(Midland Section), Chamber of Commerce, New Street, Birmingham, 7.30 p.m. Annual Meeting and Informal Discussion.

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. D. H. Wilkinson, "The Masters of Landscape Painting."

University of London, University College, Gower Street, W.C., 5.30 p.m. Miss M. S. West, "The Old Testament." (Lecture I.)

At King's College, Strand, W.C., 5.30 p.m. Mr. W. Poel, "Some Theories about 'All is True,' a play which in 1612 caused the destruction of the first Globe Playhouse." (Shakespeare Association.)

5.30 p.m. Prof. T. H. Bryce, "The Development of the Human Embryo up to the appearance of the Primitive Segments." (Lecture II.)

At Bedford College, Regent's Park, N.W., 5.15 p.m. Mons. A. Thibaudet, "Albert Sorel." (Lecture III., in French.)

Royal Institution, Albemarle Street, W., 9 p.m. Very Rev. W. F. Norris, "The Stained Glass of York Minster."

Saturday, May 17 .. British Legion (Women's Section), at the Royal Society of Arts, John Street, Adelphi, W.C., 10 a.m. Annual Conference.

University of London, University College, Gower Street, W.C., 3 p.m. Prof. Sir Flinders Petrie, "Recent Discoveries in Egyptology."

Royal Institution, Albemarle Street, W., 3 p.m. Dr. W. G. Alcock, "How Music is Made."

Journal of the Royal Society of Arts.

No. 3,730. VOL. LXXII.

FRIDAY, MAY 16, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

Wednesday, May 21st, at 8 p.m. (Trueman Wood Lecture.) Sir William J. Pope, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, "The Outlook in Chemistry." Sir Herbert Jackson, K.B.E., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

TWENTIETH ORDINARY MEETING.

Wednesday, May 7th, 1924; Admiral of the Fleet Sir Henry Jackson, G.C.B., K.C.V.O., F.R.S., in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Airth, George Rennie, London.
Broemel, Percy Rudolph, London.
Graham, Edward Alfred, Beckenham, Kent.
Webber, Henry O'Kelly, Johannesburg, South Africa.
Wreford, Ernest Henry, East St. Kilda, Australia.

The following candidates were duly elected Fellows of the Society:—

Fabini, H. V., Richmond, Surrey.
Gothard, H. A. S., Bickley, Kent.
Martynik, Jan, Gemsa, Egypt.
Sandell, H. W., North Shields.

A paper on "Wireless Navigation for Ships and Aircraft" was read by Dr. J. Robinson, M.Sc., F.Inst.P., Head of the Wireless and Photography Department, Royal Aircraft Establishment, Farnborough.

The paper and discussion will be published in a subsequent number of the *Journal.*

VISIT TO THE GUILDHALL.

About seventy Fellows of the Society and their friends visited the Guildhall on Thursday afternoon, May 8th, in response to the invitation of Mr. H. G. Downer, LL.B., a member of the Common Council.

They were shown over the Council Chamber, The Crypt, and other places of interest in the Guildhall by Mr. Deputy Alderton, C.C.; Sir Alfred George Temple, F.S.A., Director of the Art Gallery of the Corporation of London, acted as escort in the Art Gallery, and afterwards Mr. Downer entertained the whole party at tea.

At the conclusion of the visit a vote of thanks to Mr. Downer was proposed by Sir John O. Miller, K.C.S.I., and seconded by Colonel C. Napier Simpson, D.S.O., R.F.A.; a vote of thanks to Sir Alfred Temple was proposed by Mr. Noel Heaton and seconded by Mr. C. T. Courtney Lewis; and a vote of thanks to Mr. Deputy Alderton was proposed by the Secretary and seconded by Mr. F. J. Tatham.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 2nd, 1924.

Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The Chairman, in introducing Sir Lynden Macassey, said the subject of the address was, at the present moment, a very interesting, difficult, and also, he trusted, hopeful one. Sir Lynden and the audience had been able to notice during the last few days what happened to London when a considerable amount of traffic was stopped. He dared to say that if Sir Lynden had been pursuing his war-time activities, such as of Director of Shipping Labour, or dealing with the various difficulties of dilution of labour upon the Clyde, he might have been able to give some of the inner history of that difficulty; but, as it was, he hoped that it had enabled Sir Lynden to take some notes of what happened when part of the traffic of London was stopped, and also to compare it with what were the difficulties when the whole of the London traffic was in full swing.

There was no doubt that the subject was an extremely difficult one. There was seasonal traffic, race traffic, funeral traffic, sports and football

traffic, traffic at the rush hours, and traffic at different points of London which varied from time to time; there was the question of where police should be put, and many other matters upon which he need not dilate. Interesting suggestions had been made quite recently and were before Parliament at the present moment. Among those suggestions had been one of over-head roads, in regard to which he was pleased to state that Sir Alfred Yarrow, who had made a proposal and an offer to the London County Council, was present that evening and would show some slides of what he proposed as one solution of some of the difficulties of London traffic.

Probably Sir Lynden Macassey's views might have been slightly altered by recent events, but he was sure from the study which Sir Lynden had given to the subject, and from his intimate knowledge of many of its problems, the audience would listen with interest to an address which might throw some light upon the matter.

The paper read was :—

LONDON TRAFFIC.

By Sir Lynden Macassey, K.B.E., LL.D., D.Sc.,

Secretary to the Royal Commission on London Traffic, 1903-7.

When Lord Askwith asked me, as he did, some six months ago to read before the Royal Society of Arts a paper on London Traffic, the subject, important as it was then, had not become acutely controversial, and I accepted the invitation with pleasure: indeed, there was no escape. Lord Askwith, as you know, can mould a peremptory order into the ingratiating form of a request; it was that rare gift, added to his immense knowledge of industry, which made him our greatest industrial conciliator.

I had originally intended to read a paper dealing more or less critically with the political, municipal and technical questions connected with the various proposals that have been made from time to time for solving the London traffic problem. Indeed, I wrote such a paper some months ago, but in the last six days consigned it to the waste-paper basket. I felt it would not now serve any good purpose to read that type of paper because of the remarkable change in the whole situation that has occurred during the last two weeks. One of those phases of rapid transit, the strike of the tramway men and omnibus men, supervened like a bolt from the blue, and the problem ceased to be one that lent itself to critical discussion in public and became one for the judicial consideration of a Court of Inquiry. With the termination of the strike, and the conclusion of the Court's investigations, I found myself a few days ago reinvested with some liberty of speech, but that has been largely curtailed by the introduction yesterday into Parliament by the Government of the Bill relating to London Traffic, under circumstances which make me feel that I shall best assist the delicate and complicated negotiations that are involved, by laying my critical faculties for the moment under a stern self-denying ordinance. My address to-night must, therefore, take the form of somewhat general observations.

Public attention, by a turn of the wheel, has recently been directed to the congestion of traffic in London streets, very largely because of the British Empire Exhibition which is proposed to be opened shortly at Wembley. In view of the imminence of the Exhibition, Londoners became apprehensive of the growing congestion of vehicular traffic in the streets, and began to realise the importance of providing freer movement for the great masses of traffic which the Exhibition will bring into the metropolis. History is always repeating itself. It was the Great Exhibition of 1851 in London which similarly forced on public attention the deplorable conditions which then existed in regard to the streets of the Metropolis. At that time, between the top of Northumberland Avenue and the Law Courts, there were no less than seven distinct Road Authorities, each repairing the Strand at different times, and taking good care that no one co-operated with any other. That fact in itself, and the approach of the Great Exhibition of 1851, led to an agitation which finally culminated in an inquiry, out of which came the recommendation for the constitution of the great Municipal Authority afterwards known as the Metropolitan Board of Works. We can date many of our road improvements in the last century from the Great Exhibition of 1851. Will the British Empire Exhibition of this year give a similar impulse to public opinion ?

Labouring under the restrictions of the evening, I think I should probably be making best use of the wide publicity which properly attaches to any discussion in your distinguished Society if I were to focus in a convenient way before you what are the essential elements of the problem of London traffic which confront the Government and the people of London at the present moment. May I, my Lord, with your permission, proceed along the following lines? I would like in the first place to emphasize the inherent difficulties of the situation; and I think I can do that most effectively by shortly summarising them as found by the Royal Commission on London Traffic, to which I had the honour of acting as Secretary. In the second place, I would like to refer to the broad principles underlying the remedies prescribed by that Commission, and I may say in passing, that few of those remedies have so far been applied in London. The London public has almost forgotten that such a Commission ever existed, although quite a substantial number of its recommendations have been adopted in foreign capitals. I found myself, after I ceased to be Secretary, involved in lengthy correspondence with the Municipal Authorities of several Continental Cities. Thirdly, I would like to indicate how far the London Traffic Bill of the Government, which has just been introduced into Parliament, follows out and harmonises with the recommendations of the Royal Commission.

The difficulties of the London Traffic problem, as diagnosed by the Royal Commission, were conveniently summarised by them under three main heads. The report of that Commission dealt first with the streets, and with all the various questions connected with street traffic. Secondly, it examined the public transport agencies operating either on the streets in the form of tramway cars or omnibuses, or below the streets in the form of tube railways. Thirdly, it discussed the railways serving the Metropolis, whether in the form of urban railways, such as the Metropolitan District Railway and the Metropolitan Railway, or in the nature of suburban sections of what for want of a better name I may call—although the great Railway Companies do not themselves like the sobriquet—the "main-line" railways.

There can be no question of the urgency of some remedial measures being immediately adopted. Dating as far back as the reign of Elizabeth documents are in existence in the archives of the Guildhall which use language very similar to what is being used to-day, to impress upon the attention of the Government the imperative necessity even at that time of freeing what they called, the "passage" through London streets. They show conclusively that much the same problem confronted the city fathers of those days as faces the Government or the great Municipal Authorities of London at present. As to the imperative necessity to-day for action, I do not think I could say to-night anything which would improve on what was written as far back as 1905 by the Royal Commission. This is a short passage from its report:—

> "The magnitude of the population of London, and the extent of the area over which that population is spread, make the problem of locomotion specially important for London, and if the standard of movement cannot be raised to the level attained elsewhere, London must fall behind in competition with other cities, and the life and growth of the Metropolis will be slowly, but no less surely, strangled by the choking of the great arteries of traffic."

That was true in 1905, and more than true in 1924. The population of "Greater London" has increased substantially in the last 19 years, and the area which to-day constitutes "Traffic London" (because, after all, traffic laughs at municipal boundaries and parochial jealousies) has immensely widened since 1905. The distances which people travel to-day are much extended, and what may be called the "travel habit" has greatly grown and spread. Therefore, urgent as were the necessities at the time of the Royal Commission of dealing with London traffic, those necessities have since become enormously aggravated, until they represent at this moment one of the most serious and pressing social problems of metropolitan life.

The difficulties which have accumulated in regard to London's primary means of transit, namely, streets, are summarised succinctly by the Royal Commission, and I do not think I can do better than read something of what they said:—

> "The chief difficulty that stands in the way of improving the means of locomotion in London is the narrowness of the streets, and the fact that they were not originally laid out on any general plan. If the streets were of sufficient width and had been laid out on a regular plan, the congestion of vehicular traffic would practically disappear; the long distance traffic could be provided for by shallow underground railways at a cost which

would not be prohibitive; and a complete system of surface tramways could be laid down, which would carry the short distance and miscellaneous passenger traffic of London cheaply and quickly."

I pause there to make this observation: at the time of the Royal Commission the wonderful possibilities of the motor-bus had not been appreciated. The Commission then went on to say:—

> "The present unsatisfactory conditions are largely due to the fact that there did not exist in the past any Municipal or other Authority having jurisidiction over the whole area, and possessed of sufficient power and resources to enable it to deal satisfactorily with the problem of locomotion, and the other questions allied thereto. The history of the growth of London is, to a very great extent, a record of the aggregation of houses to the central, or original city, having an area of about one square mile. This central nucleus, still known as the City of London, was built, or grew up, at a time when the vast amount of business now transacted in it, and the volume of traffic that now flows through its streets, could not have been foreseen. Many street improvements have been made to relieve the special difficulties that forced themselves from time to time on the notice of the Authorities, but the great cost of such improvements, due to the high value of city property, stood in the way of any general reform, and the street accommodation of the City of London is inadequate to meet the requirements of the present day. As population increased, and business grew, various parishes and villages outside the City of London gradually became a portion of the metropolis, but were not assimilated by any central municipal authority. It is probable that the great extent to which, in early days, the river could be, and was, used as a means of communication from east to west prevented attention being given to the laying out of new streets and roads as London stretched out beyond its original limits. However that may be, the parishes preserved their separate and independent constitution and authority, and the state of confusion and administrative disorganisation that prevailed only fifty years ago is almost incredible."

The confusion and chaos flourished in profusion even when the Commission was reporting. I well remember investigating a number of cases around the metropolis where one Local Authority in the exercise of its powers under the local Building By-Laws, were actually putting pressure upon owners in their district to lay out new streets at right angles to the general lay-out of the streets in adjoining districts, so as to obstruct as far as possible the passage of through traffic, and thereby relieve the Authority, when it took over the streets, from the cost of street repairs due to traffic coming from districts beyond their own.

There are two other passages which I would also like to read:—

> "It will be seen that London, only 50 years ago, consisted of a central area of about one square mile under the Corporation of the City of London, surrounded by parishes continually growing in population and in importance; each parish a law unto itself, uncontrolled by any central, municipal, or other local authority. Under such conditions grew up the Metropolis of the United Kingdom, composed of streets laid out without plan, tortuous in direction, varying in breadth, and generally insufficient in dimensions." . . "The wants of London, as a whole, in the matter of roads and streets, have never been sufficiently considered in the past. In the early days no municipal authority existed, outside the City of London, which could deal with the whole problem in a broad spirit, and London was allowed to grow up piece-meal as local conditions or accident prescribed. No sufficient provision was, or under such conditions could have been made to meet future requirements. The streets of the present day are frequently survivals of the village roads and lanes, developed into metropolitan thoroughfares under the care of small and independent local authorities, whose views did not extend beyond the requirements of the limited areas for which they were responsible."

So that, while we find that there were in existence in Paris, Berlin and Vienna plans which laid down the general lines, dimensions and directions, in accordance with which main streets and important thoroughfares were to be developed, nothing of the kind at any time existed in London. Never any co-ordination—nothing but parochial jealousies; nothing but bumbledom *in excelsis*, each parish forming its new roads on its own petty plan, or turning what were originally cow-tracks into main thoroughfares.

Such was the evolution of London streets. As regards the means of transit on the streets, I can epitomise the Commission's conclusions; they are equally true to-day.

> "Insufficiency of mileage is not the only defect of the tramway service in London. Within the County of London nearly the whole of the tramways are owned, and in great part are worked, by the London County Council, whose policy has been consistently directed to the exclusion of private promoters from within the County of London; such tramways within their jurisdiction as do not already belong to them will be acquired, under existing powers, in the course of a few years.
>
> "In the districts of 'Greater London,' lying outside the administrative County of London, a different policy in general prevails: the tramways are largely worked by private companies. This difference of policy would not necessarily entail inconvenience if the systems on the outside were worked in harmony with those inside, so that cars should run continuously across the frontier. Unfortunately, that is not the case. The systems where they meet at the frontier are not always physically connected, and, in no case is there through running. Accordingly every through passenger is obliged to change cars.
>
> "Inside the Administrative County of London itself there are also very serious defects. Three systems of tramways are included in this area: the northern and eastern system, wholly north of the Thames; and the southern system, wholly south of the Thames. All these three systems are separated from each other by long intervals, without any connection, as will be seen by a reference to the Tramway Plan; while great districts in the centre of London, including the city, the West End, and the chief places of public resort, are entirely unprovided with tramway service. The different lines approach those districts and then break off abruptly in the middle of the street.
>
> "As a result, all the cars are obliged to discharge their passengers at dead-end terminals. At the six principal terminals (Westminster Bridge, Shepherd's Bush, Blackfriars Bridge, Aldgate, Newgate and Euston Road) nearly a quarter of a million of passengers alight from, or join, the cars every day in the streets; apart from the great inconvenience caused to all or most of the passengers, the result is a great congestion, both of tramcars and of ordinary vehicular and pedestrian traffic, at these terminal points; and the same congestion, though in a less degree, occurs at the other terminals in London.
>
> "It will be seen that, from every point of view, tramway accommodation is glaringly defective. In a great area there is no tramway service at all. Where there is such a service, travellers do not obtain the full advantage which it ought to provide, in cheapness, expedition and convenience. An 'end-on' break in the course of a journey probably causes additional expense (for two independent fares usually cost more than a through fare), whilst the consequent delay and discomfort, especially in bad weather, and the uncertainty of transshipment, are great drawbacks. Where the line abruptly terminates in the middle of crowded streets, even greater discomfort is caused, together with serious diminution of efficiency in the entire tramway service, and an intolerable congestion in the streets."
>
> "It is difficult to appreciate how such a state of things can have been tolerated so long. Whatever view may be held upon the expediency of extending tramways in London, it cannot be expedient to work those we have upon inefficient methods."

This was written in 1905. With the exceptions that at Westminster Bridge and Blackfriars "dead-end" terminals have now been abolished as a result of the extension of the London County Council tramways over Blackfriars and Westminster Bridges and along the Thames Embankment, and that through tickets are issued over the tramway, omnibus and tube-railway systems of the Underground Company, these observations of the Royal Commission are as appropriate to-day as they were when they were written.

So far as omnibuses were concerned, the Commission drew attention to the fact that their services were wholly uncontrolled, and complained of the public disadvantages that would ensue if the position were not remedied. The Commission's advice was wholly disregarded, and the trouble has now supervened in an acute and controversial form. The Commission commented adversely upon the fact that it was possible for any person who obtained a licence from the Metropolitan Police (who were the Licensing Authority for the Metropolitan Police District) and from the City of London Licensing Authority to put an omnibus on any route in Greater London he thought fit, without being subject to any control whatsoever in regard to route, comprehensiveness of service, time-table, fares, etc., thereby differing entirely from the practice in Paris, Berlin or Vienna, where the right of any person to put an omnibus on particular public streets is derived from a "concession," which imposes, in the interests of the public, certain definite obligations on the concessionaire.

In regard to railways this was and is still the position. Their construction has been entirely a question of haphazard growth. There was never any plan providing for the general lines of their development, as existed in Paris, as exists to-day in Berlin, and as did exist in Vienna. The only questions touching London railways that actively agitated the mind of Parliament or of municipalities in mid-Victorian days were three, namely, whether there should or should not be a great central station in London which would form the general terminus of all main-line railways; whether there should or should not be an "outer circle railway" connecting the main-lines somewhere outside the central districts of London and providing facilities for the exchange of goods traffic so as to avoid the necessity of passing goods waggons over crowded city lines or the cartage of goods through the congested streets of the Metropolis; and whether there should or should not be an "inner circle area" in London into which no main-line railway should be entitled to penetrate, but round which an underground railway should be built to connect up the main-line termini. The central station project was ultimately rejected; there were several fruitless schemes to construct an "outer circle railway," but the inner circle proposal was ultimately carried out.

Such were the outstanding features of the London Traffic problem. I will now endeavour, without going into any great detail, to indicate the general lines which the Royal Commission's recommendations for the improvement of the situation followed. It is desirable to bear in mind that that Commission obtained the best possible technical assistance from eminent persons of the greatest experience, in close touch with the practical realities of the problem. They were also advised by Sir John Wolfe Barry and Sir Benjamin Baker, both well-known and distinguished engineers in London, and by Mr. William Barcley Parsons, who was the Rapid Transit Engineer to the City of New York.

The guiding principle the Commission formulated—and it is, I venture to think, to-day a principle which calls more urgently for application than ever it did—was that there should be co-ordination of all means of transit. They pointed out that you cannot deal with the problem of London traffic in watertight compartments—that it is one problem undivided and indivisible. You cannot treat it as a series of separate problems whereby particular sections of London are to be served by railway or tramway or motor-bus. They emphasised the obvious and indisputable fact that no proper solution of the problem can be devised unless "Traffic London," whatever be its municipal boundaries, is treated as a whole, and unless all the means of transit serving "Traffic London" are worked in the closest co-ordination and co-operation. At that time—and even to an accentuated extent to-day—the artificial barriers which severed one transit system and another were largely the result not of traffic causes, but of parochial jealousies. Certain municipalities owned their tramways, and, of course, objected to anything in the nature of private enterprise operating in their district. In other local districts private enterprise afforded the facilities, and was denied a chance of working in co-operation with adjoining municipal systems. Therefore, the Commission laid stress on this fundamental point, that anything in the nature of a real, true, comprehensive co-ordination of the means of transit in "Traffic London" involved the repudiation by Parliament or whatever other competent authority existed, of those petty, futile and injurious distinctions as between municipal enterprise and private enterprise in matters of transit, founded not on any considerations of economy and efficiency of service, but on partisanship and prejudice.

I need not say that the area which the Commission recommended should be treated as "Traffic London" was the area known as "Greater London." Since that time, owing to the extension of London and the increasing distances people travel, an even wider traffic area than that of "Greater London" was contemplated by the recent Royal Commission on London Government.

In order to secure co-ordination the Commission laid down as the first cardinal principle, that there should, as far as possible, be amalgamation of the various systems of transit. In other words, the bigger the system, the better and the more comprehensive and the cheaper are the facilities that can be afforded to the public on an economic basis. But at that time every possible difficulty was being presented to amalgamation. In that respect this country differs extraordinarily from other countries, notably the United States of America, where every possible facility is given for the consolidation of transport undertakings, or even in countries where State enterprise is more or less the rule, as, for example in France and Germany. With the experience of all those countries to guide it, the Commission strongly urged that all possible freedom should be given to company undertakings to amalgamate. Notwithstanding that authoritative pronouncement, since that date every possible impediment has been imposed by Parliament and the Local Authorities in the way of company undertakings in the metropolitan area consolidating their respective systems. One has only to recall the history of the tube railways which exist to-day in London. They were originally authorised as local independent schemes from one point to another in the hands of separate companies, and they were only amalgamated into the present system of the London Electric Railway Company under the very greatest difficulties, and in the face of formidable opposition in Parliament. The Commission also were strongly of opinion that obstacles should not be placed in the way of amalgamation of a statutory company, *i.e.*, one incorporated by special Act of Parliament, and a limited liability company incorporated under the Companies Consolidation Act, 1908. The present position of transport companies is most illogical. Railway companies generally must be constituted by and obtain their powers from special Acts of Parliament; Tramway companies are companies incorporated sometimes by Act of Parliament and sometimes under the Joint Stock Companies' Acts, but in each case operating a system of tramways authorised by a special Act of Parliament or by a Provisional Order confirmed by an Act of Parliament. A light railway company is usually constituted by a Departmental Order, made under the authority of the Light Railways Act, to construct and work the light railway authorised by the Order. An omnibus company is incorporated under the Joint Stock Companies' Acts to work buses wherever it can get a licence. The Commission accordingly recommended that every facility should be afforded for the consolidation of transport undertakings and the working of those undertakings as one undertaking even if the owners were statutory companies or joint stock companies, or companies incorporated by Departmental Order. For some reason which it is not easy to ascertain Parliament has not given, and is not disposed to give, any facilities whatsoever for the amalgamation of these different kinds of transport companies. As a result various kinds of expedients have to be used to try and secure for the travelling public some of the advantages of consolidation, but they can hardly be viewed as entirely satisfactory. One can refer to the well-known arrangement sanctioned by a special Act of Parliament under which the five separate Underground Companies:—The Metropolitan District Railway Company; the London Electric Railway Company; the City and South London Company; the Central London Railway Company and the London General Omnibus Company—maintain a common pool. Into it they pay their net receipts after payment of working expenses and interest charges, and then the total amount of net receipts in the pool is distributed among the contributing companies by mutual agreement. The result of this complicated arrangement is that a basis is provided on which those five respective undertakings can be worked as a whole, and facilities afforded in some direction by one company which perhaps the individual means of that particular company would not justify it as a separate entity in providing. The pool supplies means for affording those facilities by placing the financial risk on the combined resources of the five co-operating undertakings. It seems inexplicable that it should be necessary for companies to resort to a makeshift contrivance of that sort as a means of effecting what ought to be effected and ought to be permitted through amalgamation of the companies' respective undertakings. The Railways Act of 1921 has provided for the amalgamation of many railway companies into four large railway groups. Why the advantages of amalgamation, which has been accepted by Parliament as the proper principle for the great main-line railway companies, should be denied to local metropolitan transport undertakings, passes ordinary comprehension.

Involved in the principle of co-ordination, which was so strongly advocated by the Royal Commission, was restriction of competition, so far as local railways, tramways and omnibus services in Greater London were concerned. This recommendation was considerably before its time, and it was many years before the public were prepared to endorse the wisdom of the view, but experience since that time has absolutely confirmed its soundness, and Parliament, in the Railway Act of 1921, has adopted and applied it to the main-line railway companies. The days are indeed past when it can be suggested that unrestricted competition affords a permanent and satisfactory basis for providing the travelling public in one large district with the most efficient and comprehensive and cheapest means of transit.

Following along and applying this general principle of co-ordination, which is the foundation of the Royal Commission's report, the Commission recommended that where amalgamations of transport undertakings for any reason could not be effected, unified working should everywhere be made possible, and indeed insisted, and were sufficiently courageous to say that if the working in any particular district of several undertakings as one meant the leasing of municipal tramways to a company to work, or meant a Municipal Corporation working all or any part of a company's tramways in its district, such arrangements should be adopted in order to ensure unified operation without any regard to prejudices or susceptibilities, if that seemed to be the effective way of providing the travelling public with the facilities of transit which they needed. But even to-day any proposition of that sort would meet with considerable political, municipal and other opposition, however outstanding were its economic advantages.

Again, proceeding resolutely towards the goal of co-ordination to which all its recommendations converged, in cases where unified working was not a practicable proposition, the Commission recommended traffic agreements providing for joint or through working, or territorial limitation or extension of operations, so as to ensure comprehensive and efficient services, and in order to eliminate overlapping and wasteful competition. Such agreements may take in practice many different forms, and involve the pooling of receipts, the division of the through fares and self-abnegation in various forms. I can appeal to the experience of those present this evening to corroborate how little of this is going on in London to-day, and what opposition is raised on all sorts of trivial grounds to every such proposal. Yet it is really of the essence of providing comprehensive and co-ordinated services that these barrier lines which exist between municipal enterprise and private enterprise should be broken down, and that apart altogether from political or other considerations, arrangements should be made for the working in harmonious unison of municipal systems of transit and companies' systems in the common interest of the travelling public.

If co-ordination was ever to be achieved, the Commission pointed out that there must be effective control over the construction and working of all systems of transport. At the time there were many objections to such a proposal. The Company said, "Why should any authority exercise control over us if they do not share in the financial responsibility of the undertaking?" The Municipality said: "No interference in our house; our local government electors should be supreme in their own district." Both forget that there was and is a considerable amount of control already existing over fares and services. If, for example, we take the question of fares, on all railways to which the Railways Act, 1921, applies fares will be subject after "the appointed day" to the jurisdiction of the Railway Rates Tribunal. On tramways the fares are fixed by special Act of Parliament or by a Provisional Order confirmed by Act of Parliament. In regard to omnibuses there is no control whatsoever as to fares. As to services and facilities, so far as railways are concerned, there is a certain amount of control exercised by the Railway Rates Tribunal or the Railway and Canal Commission. Over tramways some control is exercised by the Ministry of Transport in regard to services for workmen. The point of principle, therefore, on which the Royal Commission insisted, that there should be some fair and comprehensive and effective control over the co-ordination of, and the services and fares on all public transport systems in London, has already in great measure been accepted by the Legislature, but its partial application frustrates the benefit that would otherwise have arisen from it.

The Commission next emphasised how urgently necessary it was that the provision of all transit facilities should proceed on the lines of a "general plan," which had regard not to the circumstances of a particular district, but to the needs of "Traffic London." It pointed out, in justification of this important proposal, the haphazard growth in London of roads and of streets, of railways and of tramways, and of omnibus routes; it referred to the very different evolution of transit services in Paris, Berlin and Vienna, where transport systems were developed on the lines of a general plan. It enumerated the numerous public advantages that would result if a general plan for "Traffic London" were prepared and kept up to date by a competent authority providing for the co-ordination and future development of transit services.

In order to provide and maintain this vital element of control the Commission urged the appointment of a Traffic Board. The most effective and efficient Traffic Board would probably be some competent dictator, but that in our democratic country is a Utopian conception. It, therefore, recommended the appointment of three persons to whom numerous and responsible duties would be confided. That was the particular rock on which the Report of the Royal Commission was ultimately wrecked. The proposal immediately gave birth to a widespread agitation. Municipalities in London and in the neighbourhood expressed their firm determination under no circumstances to come under the control of anything in the nature of a Traffic Board; they insisted on their full and unfettered right to remain dictators in their own areas. A prolonged political controversy ensued, the effect of which was to stifle, for many years, any prospect of carrying into practical effect the report of the Royal Commission.

The London Traffic Bill which has been recently introduced into Parliament is a notable advance in the direction, so forcibly outlined by the Commission, as alone affording any hope of alleviation, let alone solution of the London Traffic Problem. It proposes in the first instance to constitute an Advisory Committee, consisting of a Chairman, appointed by the Ministry of Transport, 12 ordinary members and six additional members. Personally, I should have liked to have seen a small, compact, expert Traffic Board responsible to Parliament through the Ministerial Head of some Government Department, but if, from the political and municipal temper of the times, that is unattainable, then I welcome the proposal of the Government to appoint an Advisory Committee, constituted as proposed by the Bill, as a substantial approach to the ideal of the Royal Commission. The 12 ordinary members of the Committee represent the Public Departments, the Ministry of Transport, the local and highway authorities of the area which is to be treated as "Traffic London," and which is considerably larger than "Greater London." Two of the additional members are to represent the interests of labour engaged in the public transport services in Traffic London, and the remaining four will represent what I may call the Companies owning or operating those services. The main criticism of a representative committee of this kind, to deal with acutely controversial questions, is that there is a great danger of their effective decisions being shorn of all decisive action in order to secure compromise, and of this procedure degenerating into something resembling harmonious static equilibrium. I would have liked to have seen a small body imbued with plenty of dynamic force, invested with, and under no compulsion to refrain from exercising, powers of initiative, and with functions not confined merely to advising on such particular matters only as are referred to them by the Minister of Transport; but I recognise that in regard to the London Traffic Problem, the present-day principle must be "*Solvitur Ambulando.*" An immense amount of education must be effected amongst the Municipalities and all others connected with the provision of transport in London, and an attitude of mind and outlook cultivated to look on the other side of the question than that which immediately concerns themselves. All concerned in London traffic—and what citizen of London is not?—ought to welcome this Bill as being, if nothing more, at least the cradle out of which a really effective traffic authority for the Metropolis may ultimately be reared. If the right Chairman be appointed,—for with such a nicely balanced Committee, everything will depend on him,—the Committee proposed by the Bill will be able to do work of incalculable public benefit. Its very existence, and the opportunities it will provide for friendly discussion between the representatives of what have been hitherto almost hostile interests, will tend to extinguish many of the prejudices and assuage many of the asperities that have for so long militated against the provision of real co-ordination of the various traffic services in the Metropolis. In course of time I have every hope that a true spirit of co-operation will be engendered. I do not know how widely the Minister of Transport intends that the functions of the Committee are to extend—whether they are to embrace roads and streets, railways and tubes, tramways and omnibuses, or whether some more limited scope is contemplated; but I trust that their scope will be as comprehensive as is possible.

The next important provision of the Bill deals with the question of the street obstructions caused by the execution of street repair work, and by the breaking up of streets to lay pipes, cables and wires. Any of us who use the streets of London, or who lighten the burden of life by enjoying the humour of "Punch," know what an unnecessary and perfectly ridiculous amount of obstruction is caused by the inveterate and insatiable passion of every authority with statutory powers over the thoroughfares of the metropolis, to break them up at different times, without any sort of co-ordination, and make them almost impassable for traffic. The Bill represents a praiseworthy attempt to compel all such authorities to arrange a normal seasonal programme for any work involving interference with the surfaces of streets, so that, except in case of emergency, all such work may be done at one and the same time—a reform insisted on by the Royal Commission and regrettably overdue.

The next important clause in the Bill is the power which it is proposed to confer upon the Omnibus Licensing Authorities in "Greater London," that is to say, the City Police in the City of London, the Metropolitan Police in the County of London, to attach conditions to omnibus licences. That is absolutely essential if an efficient, comprehensive omnibus service is to be secured. There can be no reason whatsoever why we in London should be in a worse position than other cities abroad. It cuts at the very root of providing a comprehensive and efficient omnibus service if it be possible for any person who obtains an omnibus licence to put his omnibus on any route he thinks fit for just as long, or for such periods of the day as he chooses, and thereby skim the cream off the traffic of those routes and evade what ought to be the responsibility of any public transit undertaker, namely, to provide traffic facilities, not merely on a route at profitable times, but at all times, and not merely on the most profitable routes, but on routes which are not so profitable. In traffic operation good routes must pay for bad routes; by no other means can comprehensive facilities be provided.

It can hardly be suggested that the proposal in the Bill constitutes any very onerous restriction on the liberty of omnibus licensees. Indeed, when one considers what the public interests demand, and what is the existing practice in foreign capitals, it may be argued, and not at all unfairly, that the provisions of the Bill will preserve for the metropolitan omnibus licensee a latitude of choice in regard to when and where and how he will operate his licensed omnibuses very considerably greater than that to which he might reasonably be restricted in the interests of the welfare of the travelling public of "Greater London."

As complementary to the powers of the Omnibus Licensing Authorities in "Greater London" to attach conditions to omnibus licences providing for a proper service, the Minister of Transport himself takes power under another clause in the Bill to limit, either generally or during particular hours, and subject to certain safeguards, the number of omnibuses plying for hire in any street or part of a street within "Greater London," when he is of opinion that by reason of the width of the street, or the existence of alternative facilities for the conveyance of passengers along the street, or in its vicinity, the number of omnibuses plying for hire along the street is excessive, and the Minister may determine the omnibus proprietors who shall solely or jointly be permitted to operate their omnibuses through any such street. A power such as this was thought necessary by the Royal Commission as far back as 1905. How much more is it necessary to-day to deal with the swelling flood on London streets of heterogeneous and unnecessary omnibuses, which are being pressed into operation, not to provide a permanent and reliable service for the benefit of the public, but to snatch a transient profit at the cost of tramways and tube railways, which, unlike the mobile omnibus, are anchored fast to definite routes, and cannot be diverted from route to route as fancy dictates or profits attract. All such unnecessary omnibuses are a public detriment and not a public benefit. The public is no better served. They are merely carried on an omnibus and not on a tube railway. In the end the public must inevitably suffer. Tube railways and tramways must of a certainty reduce the facilities they offer to the travelling public if revenue which is legitimately theirs, and for which so large a permanent investment has been hazarded, is to be diverted from their already slenderly filled coffers into the pockets of irresponsible omnibus proprietors. One important comment does arise upon this clause of the Bill. It seems unfortunate that the Minister of Transport is taking no power under the clause to regulate services upon metropolitan tramways, whether owned by companies or by local authorities.

In addition the Bill confers upon the Minister of Transport on lines recommended by the Royal Commission power to make a large number of regulations, in regard to preventing obstructions in the streets and facilitating passage through them, subject to disallowance by Order in Council on an address being presented to the King, praying for such disallowance by either House of Parliament. The various matters in respect of which such regulations may be made are too numerous to mention; they are set out very fully in the Third Schedule to the Bill.

I may, in conclusion, sum up the effect of the Bill now presented to Parliament, by saying that it marks an earnest attempt on the part of the Government to go a considerable way towards carrying into effect the recommendations of the Royal Commission on London Traffic, although there are, as has been pointed out, very important and very serious omissions. There is one particular deficiency. The Bill contains no provisions enabling transit authorities, whether Company or Municipal, to enter into agreements providing for the co-ordination of their respective systems under any arrangement which seems mutually satisfactory, and involving it may be pooling of traffic revenues and their distribution as agreed. There should be no objection to giving effect to this all-important recommendation of the Royal Commission. Such a power should be conferred upon the owners of transit systems in London, be they municipalities or be they companies. No political or municipal prejudice should be allowed to weigh against the crying needs of London's travelling public.

This is a subject on which, no doubt, a number of distinguished gentlemen whom I see present, and who are closely connected with the London Traffic Problem, may possibly desire to speak, and, therefore, I shall not occupy the time of the meeting further, except to say this. Speaking under the limitations of the moment, my object in this address was a limited one, namely, to indicate what were the fundamental difficulties of the problem; secondly, to show in broad outline and in some attempt at balanced perspective the main lines along which the Royal Commission, after four years of close investigation in this country, on the Continent of Europe, and in the United States of America, assisted by the most expert and experienced traffic and technical advisers of the day, were of opinion that the solution of the problem lay, and, thirdly, to indicate how far the present London Traffic Bill of the Government carries into practical effect the recommendations of the Commission.

My Lord, ladies and gentlemen, I thank you most profoundly for your kind and sustained attention, and I venture to hope that what I have said may afford some basis for a profitable and interesting discussion.

DISCUSSION.

Sir Alfred Yarrow, Bt., M.Inst.C.E., F.R.S., in opening the discussion, thanked Sir Lynden Macassey for having placed before the audience in a very clear way one of the most difficult problems of the day.

The congestion of the traffic in London had greatly interested him of late, because he had been one of hundreds of thousands of people who were anxious to hurry on, and who had been kept waiting owing to the congestion that occurred,

(1) Partly through one line of traffic crossing another on the same level,

(2) Partly through the traffic being stopped to allow pedestrians to cross the road, and

(3) Partly on account of horse vehicles, which could not keep up the speed of the present day.

If the value of the time people lost owing to such stoppages could be estimated, it would work out to a colossal sum,—many millions sterling per annum; and, having in view the loss to the nation through such waste of time, money might well be spent in organising various methods of alleviating the present congestion.

With regard to horse traffic, two years ago he had been in Seattle, one of the most rising cities on the Pacific coast. He had been struck by the fact that horses appeared to be extinct. He had taken a drive for three hours to see the city, and during that time he had only seen one horse, and it was lame! That was an example which foreshadowed what would probably happen in in this country in the distant future, and, therefore, any arrangement made should have this change from horse to motor kept in view.

As regarded facilitating pedestrians crossing the roads, in Seattle they had an excellent system. At certain intervals there were two white lines, about 15 feet apart, painted across the road. From one pair of lines to the next pair the traffic was allowed unlimited speed. (In Seattle motorists were not fined for going too fast, as here, but for going too slow!). When a car approached the white lines the chauffeur had to slow down to three or four miles an hour and just crawl across the space allotted for pedestrians to cross. If anyone wished to cross the road in safety he must do so at such places, as between the lines all cars went very slowly and could therefore stop instantly in case of necessity. If pedestrians crossed at any other places they did so at their own risk. That scheme worked exceedingly well, and he saw no reason why something of the same kind should not be adopted in this country. It would avoid the police stopping the traffic for people to cross. If such crossing places were adopted say in Regent Street there would be six or eight between Oxford Street and Piccadilly Circus.

So much for the horses and for people crossing the roads.

Coming to the most important difficulty of all, namely, where two lines of traffic crossed on the same level, it did not require the wisdom of Solomon to see that when one line of traffic was passing the other must stop. The only way to prevent that was for the lines of traffic to cross on different levels. That had been proposed over and over again, and was carried out in railway practice. The one line of traffic could pass through a tunnel, or it might pass over the other, which ever might be most advantageous under the special

Fig. 1.—Photograph of Model illustrating High Level Crossing so that the Traffic in one direction does not interfere with the Traffic passing at right angles.

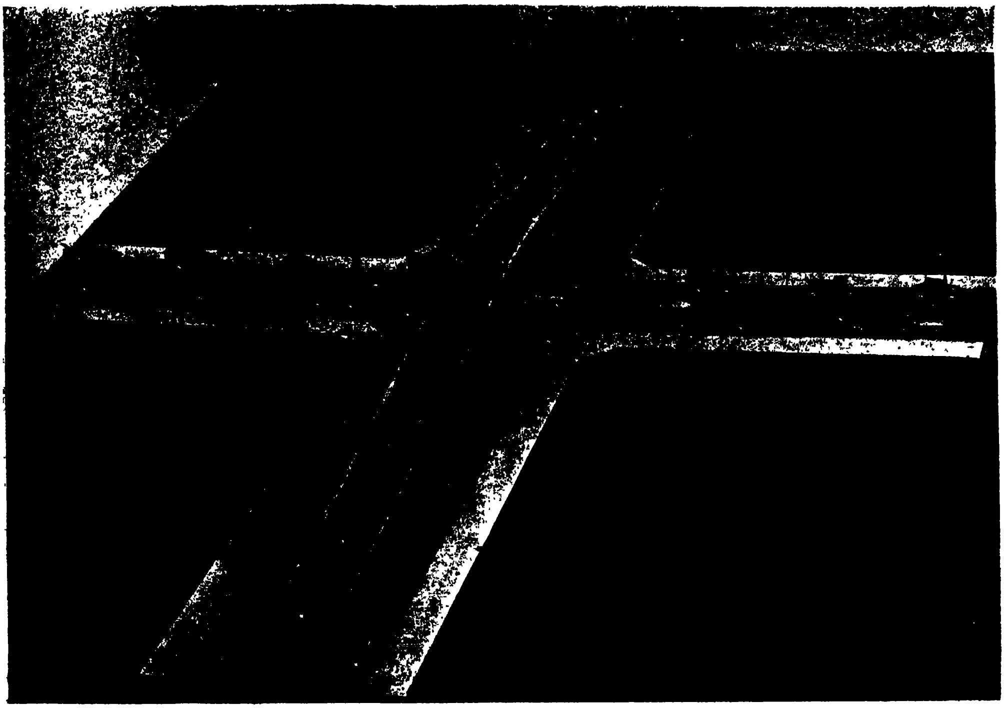

FIG. 2.—Photograph of Model illustrating a High Level Crossing so that the traffic in one direction does not interfere with the traffic passing at right angles.

circumstances of each case. In the London streets it was difficult to burrow underground on account of sewers, water-pipes, gas-pipes, electric mains, underground railways, etc., and, therefore, in most cases, it only remained for the crossing to be effected by means of an elevated road.

He had had some models made (Figs. 1 and 2), slides of which would be thrown on the screen, showing how that plan could be carried out. With regard to the height above the roadway which was crossed, 16′ 6″ would be sufficient to allow for a 6ft. man to stand on the top of an omnibus and leave 12 inches clearance.

With regard to the width of roadway for the high-level crossing, if 18 feet could be obtained for two lines of traffic (one going in one direction, and one in the other) it would be desirable (see Fig. 3); but 16ft. would be sufficient, and that was found ample in actual practice in the Blackwall Tunnel.

It might be necessary to have a kerb to keep each line of traffic distinct from one another, so as to avoid any possibility of collision.

On each side of the elevated road there should be room for a car to stand by the side of the pavement, and also one to pass; but as they would not be passing in opposite directions he ventured to think that 16ft. certainly would be ample. He believed he was right in saying that 15′ 6″ was considered sufficient by the Glasgow Authorities.

With regard to the incline, he thought that one in thirteen was suitable. He lived near Guildford. Guildford High Street had a rise of one in ten, and that was ascended by all kinds of vehicles, and he had never heard anybody complain that it was too steep. Therefore, if an incline less than

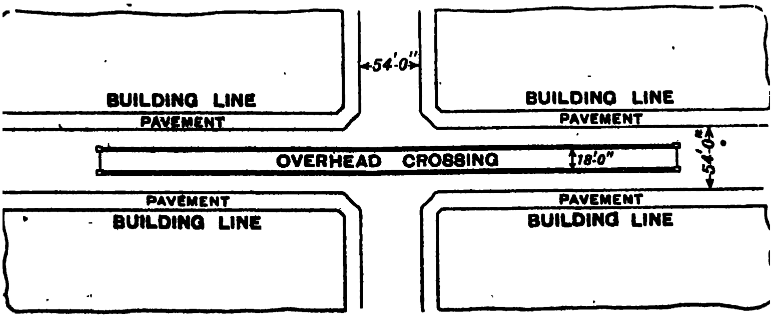

FIG. 3.

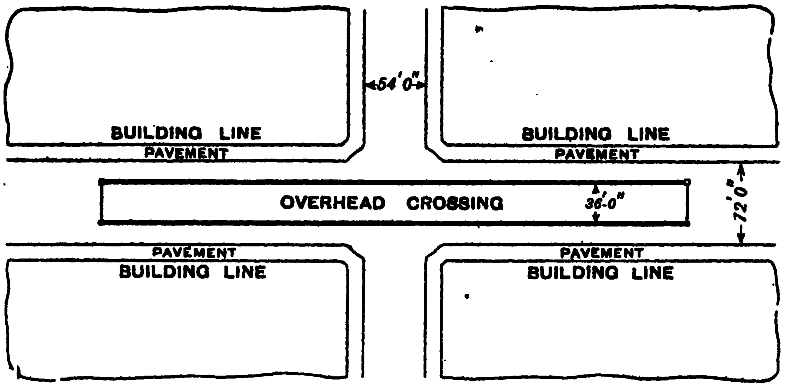

FIG. 4.

Guildford was adopted, that should meet all necessary requirements.

There was one point in connection with a high level crossing which was a decided advantage to the property owners on each side, and that was, motors could be parked in safety under the approaches and were thus easily available, instead of, as at present, having to be sent up a side street where one often did not know where the car was to be found. Therefore he ventured to think that any contention that a high level crossing was a drawback to the shops was more than counteracted by the facility for parking the cars.

Under the present circumstances he was afraid the width of the streets would never admit of more width for the overhead road than sufficient for two lines of vehicles going in opposite directions; but in any new roads that were made it would be wise to have the overhead road wide enough to take four lines of traffic. (See Fig. 4).

The various views which would be thrown on the screen showed different views of the model, and he thought they would speak for themselves. Fig. 3 showed the width desirable in order to carry out the scheme, with one line of traffic in each direction. over the high level crossing. Fig. 4 showed a sufficient width of overhead roadway to admit of four lines of traffic along the high level crossing, two in each direction. He suggested that for new roads, where there was likely to be congestion due to two lines of traffic crossing on the same level, the wider overhead road would be desirable, involving a total width between curbs of 72 feet. If the width of the road between the curbs was 40 feet, then the width of the passage at the sides of the high level crossing would only admit of one line of vehicles, and the police should have authority to insist that no motors should remain standing. If 48 feet width of road between the curbs were available then on one side of the high level crossing there would be room for two vehicles to pass, and on the other side there would be room for only one line of motors, and on this side the building line might be set back at some future time. With reference to appearance, the scheme gave a fine opportunity for the architect to show his artistic skill in designing something that would correspond to the surroundings, and Fig. 5 showed what such a structure might be like.

If arrangements were made for people to cross the road as was done in Seattle with success; if horses were forbidden to go along the main thoroughfares; and if there were overhead roads such as he had indicated, the traffic difficulty would possibly be met.

Of course, in dealing with this subject it must be borne in mind that whatever number of cars there were on the roads now, in ten years' time there would probably be double the number, which corresponded to the increase which had taken place during the last five years.

He would point out that it was reasonable, as the road traffic was increasing much more rapidly than the foot traffic, that a slice might be taken off the pavement in cases where the building line was set back, and not for all the increased space to be given to the foot passengers.

He might mention, in conclusion, that he had no financial interest whatever in any scheme. What he was doing was on public grounds, because the present condition was intolerable and it would get worse and worse every day.

SIR GEORGE HUME (Ex-Chairman, L.C.C. Highways Committee) said that he had some trepidation in speaking on this subject, because unfortunately the London County Council seemed to carry with it an atmosphere of controversy which did not tend to the useful solution of the problems with which the Society was dealing that evening. It was interesting to have the opportunity of hearing Sir Lynden Macassey who was so closely connected with this problem at a time when there was not so much fever in the illness as there was to-day. It was good to hear him lay down once more the principles which the Royal Commission had set out so clearly and apply them to the Bill which at the present moment was before the House of Commons. There had been a good many happenings since the days of the Royal Commission. There had been enquiry after enquiry. The House of Commons had considered the matter through special Committees. There had been a Committee

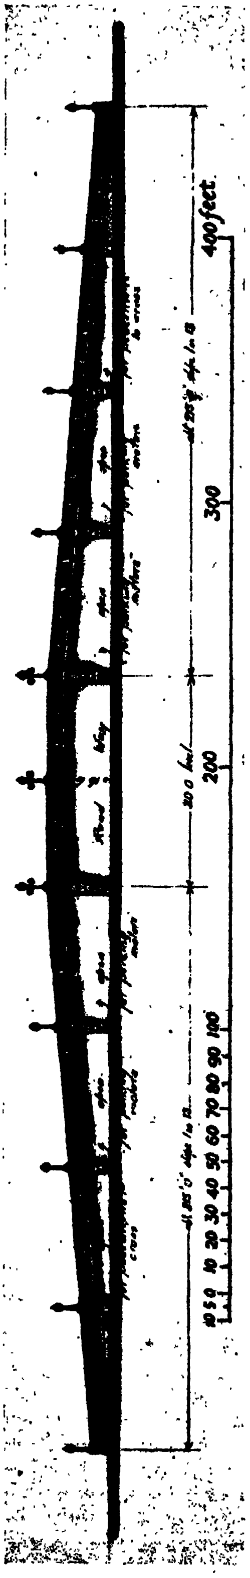

FIG. 5.—Elevation of Proposed High Level Crossing.

sitting at the Ministry of Transport under Mr. Kennedy Jones, of which the speaker was a member, and on which an attempt was made to see how this problem could be dealt with in such a way as to obtain legislative sanction. So far as the London County Council was concerned it had been wide-awake to this problem for many long years. By resolution, ever since the Royal Commission sat, the County Council had been pressing for the setting up of a Traffic Board, but successive Governments had had more interesting matters to deal with and London had gone on its way. Recently, no doubt, owing to the intervention of a number of buses which did not happen to be in what was known as the "combine," they were finding the streets rapidly filling up with traffic which had undoubtedly very much emphasised the difficulty from which they were suffering. The recent strike in the London traffic industry had added a picturesque touch to the problem. London had been denied its trams and omnibuses for something like ten days. The solution of that difficulty and the return of the men to work was, he believed, largely facilitated by the undertaking which the Government gave that they would bring in the Traffic Bill which they found in the pigeon holes when they took office. This Bill was to have been brought forward last year, and it had come before them with just a few touches to give it a little local colour. There were those who said that this was a problem which ought to be handled by the Municipal Authorities. On the London County Council they took that same view, but they took it as an ideal. They did not like the interference of any Government Departments. But it had been impossible to set up any Municipal Authority. Suggestion after suggestion was made and finally, in a very rash moment, the suggestion was made that London government generally should be remodelled. The Royal Commission sat on it, but the result was that in another sense it did sit on it! The problem was still with them. It was a burning problem, and the line they took at the London County Council was that in view of all the jealousy between authorities, no matter who brought forward the proposal, they for once should do something original, and although they did not like the Bill now before Parliament they were not going to oppose it. It was the only practicable thing they could hope for at present. If this Bill was scrapped there was nothing to replace it, and they would have to go blundering on from year to year without finding a solution for this problem. On those grounds the London County Council decided not to oppose the Bill, but hoped to make certain amendments in Committee, because happily at the moment a Government was in power which did not mind having its own measures cut about. Sir Lynden Macassey had touched on the question of co-ordination, a very interesting subject. That very troublesome body, the London County Council, had even awakened to that aspect of the situation. It did not allow itself to be absolutely paralysed by the contemplation of the iniquities of the "combine," and as good citizens, seeing that the State would do nothing for them, they did get together and make a most serious attempt to see if something could be done for themselves. In order that it should not be suggested that the London County Council was attempting to give away London's birthright to private enterprise, they succeeded in capturing the Minister of Transport, whose representative presided over the discussions, and so gave a guarantee that everything was fair and square. He ventured to say that it was not the fault of the "combine" or the London County Council if this problem had not been dealt with. All three parties on the Council came into these negotiations, but before they came to the end of their labours one party dropped out while another refused to accept the final conclusions. He did not wish to take up more of the time of the Society, because this was a subject on which a great deal might be said. It was something to have succeeded in getting a certain number of men representing different interests around one table to talk over this problem with an earnest desire to solve it. In that respect some good work would be done by this new body during the first three years of its existence, and then it might go out of existence and something else take its place. But it was very urgent that something should be done.

Colonel C. H. Bressey (Ministry of Transport), said at that late hour it was very difficult for anyone to speak adequately of London traffic, and as he was a representative of the Ministry it was as well that his words should be as few as possible. Obviously any discussion regarding policy on his part would be out of place. He had had the honour of working with Sir George Hume in connection with many problems relating to London traffic, and he knew what a weighty part he had played in these discussions. As an expert he ranked second only to Sir Lynden Macassey, the author of the great text book and encyclopædia on London traffic. There was no doubt at all as to the wide area which the London Traffic Authority would have to control. One could see to-day the most unexpected developments taking place. Any Traffic Authority set up must have an area extending as far as possible into those districts outside London whose development was still open to control and could be usefully controlled in the public interest. For example, take the air service: the aerodromes were as far afield as Waddon and Hendon. The air service was not meant particularly to serve the places at which the aerodromes were located, but it was meant to serve London, and the interests of London traffic in this particular might be supposed to extend to those places. That was a hint as to how far afield London's traffic interests might stretch. Sir Lynden Macassey had made a reference to the extraordinary parcellation of London, its minute sub-division, and in this respect he would like to mention a fact recently published in *The Observer* referring to the state of Lambeth 100 years ago, when in an area of one square mile 16 toll gates were set up for the restriction of traffic. Many of the authorities of that day and perhaps later were more concerned in restricting traffic than in promoting its movements. In the East End one saw the side streets which had been narrowed down in order that, in the turnpike era, the traffic should be driven off those narrow streets which produced no revenue into the turnpike road which did. As Sir George Hume had said the great point was not to search for impossible ideals, although these might come later, but to seize some practicable solution which would stand a chance of acceptance, perhaps with some reluctance, by all concerned. In 1855 the Metropolitan Board of Works was set up. That was succeeded in due time by the London County Council, with far greater powers, which had worked with far more credit to the Metropolis. Something of the same evolution might take place with regard to traffic, and it was the desire of them all to see the developments in traffic controlled to the best interests of all the citizens of London.

Mr. Frank Pick (Assistant Managing Director, Underground Railways) said that he had listened with much interest to Sir Lynden Macassey, and he agreed with him that the problem was not solved by reviewing simply its technical aspects: it had become political. One aspect of the problem had been more emphasised than others during the last few weeks. At one time the discussion turned upon the various means of surface transit on the one hand and the Underground Railway on the other, and one seemed to be in a fair way to arriving at a solution of the problem by a consideration of the functions of these two forms of traffic. For the shorter and more casual traffic the omnibus or tram had advantages, while for people who had to make longer journeys to town the advantage lay with the Underground Railways. In the many discussions that had taken place they had hopes that they could have come to some agreement whereby their respective functions did not clash too much and a measure of co-ordination suitable to all concerned might be arrived at. But now they had reached a different point of view. The recent strike had shown that the three main forms of transit—trams, omnibuses and the Underground Railway—had different economic capacities. The tramways and omnibuses earned approximately the same amount of money for each mile they ran on the streets, in spite of the larger capacity of the tramways, yet the tramway represented an expenditure at least four times as great as that of the omnibus, and therefore it required four times as great a margin. The relative expenses of the vehicles were not sufficiently far apart to maintain that additional margin of income. Railways did not earn so much per mile as either the buses or the tramways, and their capital cost was at least 20 times as much as that of the buses, so they had to earn a still larger margin. It had been found that there was the greatest difficulty in securing that margin for the Underground Railways, and this difficulty had been evident before the Underground

Railways were grouped together in what was now known as the "combine." The railways so grouped had themselves different earning capacities, the District Railway, for example, had a different earning capacity from the Central London Railway. Yet these railways had approximately the same expenditure and relatively the same costs to meet, so that one of them might be prosperous and another not prosperous. It all seemed to point to the principles laid down by Sir Lynden Macassey that to meet this new difficulty they must have a common financial interest in London traffic so as to provide a complete solution. If the London Traffic Bill should go through it might be subject to improvement with time, as Sir George Hume hoped, and a proper control of traffic might be instituted. When that happy day arrived perhaps their own life would be more peaceful than now, and London not less well served than it was to-day. He congratulated Sir Lynden Macassey on his address.

Colonel J. A. A. Pickard (National "Safety-First" Association) said that in the last five years the number of street accidents in the Kingdom, excluding London, had increased by over 110 per cent., but in London, thanks very largely to the campaign carried on by the Safety-First Council the increase had been only 65 per cent. There was no doubt that the great increase in the number of motor vehicles in the last five years must very seriously aggravate the danger to be met. He thought that the driver of a motor vehicle was often unnecessarily blamed for accidents which occurred, and that in many cases of accident he suffered just as much as, if not more than, the person who was injured, because the blame was not his own. Anything that could be contrived to make the movement of London traffic more easy and more safe for the public was to be welcomed and if the Traffic Bill only brought them one step nearer to what might be the correct and logical solution they in London would be grateful for it. He would like to add a word in appreciation of Sir Lynden Macassey and his lecture. The speaker had been connected with London traffic for a good many years, and the report of the Royal Commission had been a "bible" to them all.

Chief Constable Arthur Bassom (New Scotland Yard) said that he had only just returned from Paris, where also the traffic conditions were very interesting, and he was quite unprepared to say anything of great point in that discussion. He would like, however, to utter two regrets that he felt on listening to Sir Lynden Macassey's paper and the discussion. The first was a regret that Sir Lynden should have scrapped his paper, because he felt sure that it would have contained a great deal of material which to Scotland Yard at least, would have been most instructive and would have given the cue upon which they might have obtained new ideas for the working of London traffic. His other regret was that the discussion that evening should have turned so largely upon one phase of the London traffic problem, —namely, the passenger carrying side. The London traffic problem was made up of many units, in which, he agreed, the passenger side played a very important part. But it was not the only part with which the police in regulating the traffic were concerned. He did not want at that late hour to enter into the various phases that made up the traffic problem, but he would have liked the discussion to have turned upon more general subjects, dealing with that problem as a whole, so that one could have crystallised the feelings of such an assembly as that and an indication could have been obtained as to the lines to be taken for the amelioration of the traffic difficulty. That difficulty, although accentuated at the present time, had been with them since the time of Charles I. Whether the problem was more acute now than it was in those days he was not old enough to say! But one knew quite well that in going through the various historical aspects of the London traffic problem, many attempts had been made to solve it, though nothing definite had been done, and it had been largely left to the efforts of the police to get the increased number of traffic units through streets which were not appreciably wider than they were 50 or 60 years ago. The traffic census which was taken year by year showed that the traffic units were increasing in number and in size. The average speed of the London traffic was also, by reason of the congestion, becoming lower than it was some years ago. He was not prepared to assent to the figure given elsewhere a little time back, but it could not be disputed that London traffic was becoming slower by reason of the greater congestion, and no real attempt had been made to increase the facilities for the traffic to pass through the given spaces. He thought that, instead of looking so far to the future, it was necessary for those who were dealing with the traffic problem to look first of all to the present and to consider what was required. The principal requirement was an immediate amelioration of the traffic problem. It was of no use trying to visualise what was going to be done by a Traffic Advisory Committee years hence. It was essential to get to work at once. There was one point he would like to touch upon with regard to Sir Alfred Yarrow's speech and his reference to the white lines painted across the road at intervals. He would like Sir Alfred Yarrow to take the idea for those white lines across to Paris and get them adopted there. Whether the white lines would ever be recognised by the average Londoner he did not know, but his experience, which covered a number of years, was that the average Londoner would cross the road at whatever place he wanted to, irrespective either of subways or of special indicating marks.

The Chairman (Lord Askwith) thanked Sir Lynden Macassey and indeed all the speakers for the most interesting remarks they had made. There were many things which occurred to him, but it was too late for him to elaborate them. One main issue was that it seemed that now and in the past London had been extraordinarily conservative and had never got ahead with the facilities which it ought to have. A London had grown up through the ages, and its lines of buildings could not be altered without vast expense. There was present to their minds a mass of problems altering continually, changing even at different seasons of the year, which had to be coped with and required ingenuity and skill for their solution. There were certain broad lines which appealed to their intelligence. They all remembered a time when the horse was very prevalent in London, and he remembered how people before lunch, sitting in a Club in Piccadilly, would bet on the number of grey horses which would pass along Piccadilly in five minutes. To-day, one might wait almost for hours in Piccadilly without seeing one. He would not be at all surprised to find horses almost banned from the streets of London. It might be too, that in time the tramways would be eliminated and a much more mobile method of transit by omnibus or motor-car would be employed, without a fixed rail in the middle of the street. But even that would not offer a complete answer to the London traffic difficulty, because new phases of the problem were certain to arise. How would it be, for instance, when someone came down with a flying machine and desired to alight at a shop or to stack his machine at a cab-stand? With the progress of science and invention a great many more changes would take place, but at the same time they were very far behind, and if any general ruling up to a certain point could be attained within reasonable time, then at least, they would see either that they were going upon the right line or else upon a wrong line which they would have to reverse. It might be that they would have to come to dictatorship instead of having Advisory Councils; that might be the alternative to leaving the public to themselves without attention. As to Sir Alfred Yarrow's idea for crossing the street, he would rather like it to be tried in Paris first, as the last speaker suggested. He was not very hopeful of new directions of this kind. What was the fate of the "Keep to the Left" campaign? He heard an excellent speech from Lord Lansdowne who stated that as a law-abiding citizen he set out one day to try to keep to the left, with the result that he had never been more abused in his life than he was on that day. Could not Sir Alfred Yarrow present to the London County Council twelve movable bridges which could be clenched down and tried in some suburban crossings instead of being used in the first instance in Oxford Circus, where a good deal of opposition would be forthcoming? Such suburban crossings might gradually educate the Londoner up to the idea. He moved a vote of thanks to Sir Lynden Macassey.

The vote of thanks was carried unanimously.

Sir Lynden Macassey said that he thought he could best show his appreciation of their kindness by saying nothing more.

The meeting then terminated.

Mr. Arthur F. Evans writes:—

There have been numerous regulations, suggested or made, by the Governing bodies with the object of increasing the efficiency and safety of Road Traffic, but a "Rule of the Road," which should be the foundation of all these schemes has been denied all serious consideration.

I have already suggested a series of rules which I consider should be Statute Law, and the following rules I have selected as being the most important.

(1.) All vehicles shall keep to the left hand side of the road.

(2.) A vehicle shall keep clear of any other vehicle that may be on its left-hand side.

(3.) Traffic on main roads shall have precedence over all other traffic.

(4.) Traffic on all roads shall have precedence over traffic emerging from private drives, fields, farm yards, etc.

(5.) All vehicles altering direction or speed shall signal.

(8.) All vehicles shall carry lights in accordance with the classification and every vehicle (including cycles) shall exhibit a red light visible from all points behind the vehicle.

(9.) Pedestrians shall have equal rights to the road as vehicles, providing they comply with the rule of the road, except as regards lights and sound signals.

(13.) No livestock shall be allowed on the road unattended.

(14.) At night, those in charge of livestock travelling on the road shall carry a hand lantern, etc.

(17.) All other things being equal, the onus shall rest with the vehicle that has altered its speed or direction in case of accident.

I should like to point out that Rule (1) means *keep to the left*, not simply pass to the left, and Rule (2) is a development of this Keep to the Left Law. The latter provides the long-wanted direction in the case of two vehicles converging at cross roads, forks, etc.

Rule (3) was not really practicable till the roads were classified, while on the other hand the classification of the roads is of little value without this law.

The only laws governing the traffic at the moment are some vague "Laws of Custom" and local Police Regulations.

NOTES ON BOOKS.

Among the Wild Tribes of the Amazons. By Charles W. Domville-Fife. London: Seeley, Service and Co., Ltd. 21s. net.

Although one can steam in luxury two thousand miles up the Amazon, and in considerable comfort for another thousand miles, the fringe of civilisation on either side of the river is of the narrowest, and in many places a few steps will carry one into primeval conditions. A region about the size of Europe is still practically unexplored, and probably will long remain unexplorable. The forests, which extend for hundreds of miles unbroken, are so thick that the traveller must hew his way through them; the rivers which flow into the Amazon are for the most part ridden with malaria and swarming with voracious monsters from alligators to mosquitos; while in the forests lurk tribes of anthropophagous savages, whose arrows and blow-pipe darts are dipped in the deadliest poisons.

This is the kind of country which Mr. Domville-Fife set out to explore. He made his way up various tributaries of the Amazon, generally in a canoe accompanied only by two natives. His principal object was to study certain tribes of whom little or nothing was hitherto known, and he succeeded in bringing back a great deal of information about them and some exceedingly interesting photographs. These were only obtained at imminent risk of his life. Apart from such dangers as malaria, beri-beri and other tropical diseases; the risk of running short of provisions or of losing his way in the forests, he found that in many places the natives viewed him with intense suspicion —a suspicion that had too often been justified by the brutal excesses of rubber collectors—and on more than one occasion he was within an ace of falling a victim to a club or a poisoned arrow.

The Amazon Valley is extraordinarily rich in timber and vegetation generally. *Inter alia*, it possesses many drugs which are hardly known to our pharmacopœia, but which the native medicine men use with considerable skill. A potion known as *yagé* is said to have proved exceedingly beneficial in cases of beri-beri, and it is also alleged that it produces curious telepathic effects in those that take it. Some of the tribes visited by Mr. Domville-Fife practise massage and physical exercises with remarkable results.

It is quite impossible to follow the author on his precarious journeys without a great deal more space than is available here, and without a map. It must suffice to say that he tells a story of intense interest in a graphic style. His descriptions of the great rivers which he explored, of the vast silent forests on their banks, with their wealth of vegetation and the amazing beauty of their flowers and butterflies, make up a volume which all lovers of travel will read with delight; nor will their appreciation be diminished by the fact that in spite of the many dangers which menaced him from the savage tribes he visited he left amongst them no one to mourn through the wanton crack of his rifle.

Jacquards and Harnesses: Card Cutting, Lacing and Repeating Mechanism. By Thomas Woodhouse. London: Macmillan and Co., Ltd. 25*s*. net.

The story of the Jacquard loom, or perhaps more strictly, the Jacquard system of control, takes us back about a century and a half to the young J. M. Jacquard whose tastes from childhood had been discursively mechanical. His parents left him an interest in some kind of weaving industry at Lyons, but he very soon failed and lost everything; apparently at this time having been engaged in what seems to have been regarded as an utterly mad scheme for controlling the loom action by perforated sheets of cardboard.

So the impoverished Jacquard became a soldier, and in 1792 he fought against the revolutionary army; but matters becoming more settled he renewed his labours with some success, and acquired a germ of fame, and one version of the story is that he was officially called to Paris, where he went in fear of being punished for his activity against the revolutionary party. On the contrary, he was received in a spirit of high appreciation by Napoleon, Carnot and other eminent persons; now his troubles were ended and he lived to see his method of automatic pattern weaving established as an industry at Lyons.

Mr. Woodhouse's magnificent volume of 430 large octavo pages, includes over 400 admirable illustrations in the text, many of these illustrations, like Fig. 267, being a number of illustrations grouped together, while others (Fig. 224 for example) represent complex machines with 50 or 60 references to parts. The work, however, is not of the nature of a general treatise on the Jacquard loom, nor is it in any sense a handbook of Jacquard weaving; its limitations being clearly indicated by the title. Some of the devices for controlling repeats, reversals and special adaptations are quite remarkable, and although the work is intensely technical, and moreover, departmentally technical to the weaving industry, all members of the Society may learn something from it as to general method and overlap of method on method under high complication. Remarkable and interesting combinations are involved in devices for weaving extra wide curtains, damasks, or comparable unit-systems or sheets, which often include direct and reversed aspects of the same device with repeats, overlaps, changes in the aspects of twilling and also a complete or four-sided border to each unit-system. A device of this kind, consisting of a broad loom, under the control of four Jacquards is represented as a back view on p. 70 (Fig. 45).

Applications of the Jacquard weaving system to Paisley shawls, plaids, carpets, multi-coloured tapestry and to many other textiles are considered and illustrated.

The general reader will get some notion of the surprising extent of the Jacquard industry at present, notably as replacing printing and expedients incidental to printing, like multiple mordanting, resists and discharges. The Jacquard weaver cannot fail to learn many new facts and notions, and manufacturers in other branches of the industry will be able to gather much as to economy of manufacture in its broad aspects. Although advertisements in technical books are unusual and perhaps generally undesirable, there appears to be excellent reason in this case for advertisement pages which in themselves indicate the present magnitude of the Jacquard industry.

X-Rays and Crystal Structure. By Sir W. H. Bragg and W. L. Bragg. Fourth Edition. London: G. Bell and Sons, Ltd. 21*s.* net.

In the preface to the present edition the authors refer to the difficulties of finding "words which remain suitable in the face of a succession of new researches." We may observe that this is a difficulty incident to all theoretical considerations based on rapidly progressing experimental work; but the mere fact of the authors having recognised this difficulty has evidently helped them to do much to render the work before us clearer in meaning than the greater number of books which deal with the theoretical aspects of experimental work. Language, at best, is very imperfect in relation to the higher branches of human knowledge.

The basis of those studies which have made the position of Sir W. H. Bragg so pre-eminent in modern scientific progress is the observation of Von Laue that X-rays can be diffracted like light, provided that we can find something of the nature of a diffraction grating but much finer than anything which can be produced by ruling, as for example a crystal. Thus it may now be considered as demonstrated that X-radiations are essentially, in their nature, similar to light but so extremely ultra-violet that the wave-length is very approximately about one ten-thousandth that of light (*i.e.*, real light or visual light); further the diffraction grating for this extreme ultra-violet must be of the gauge or measure or order of the distances of the molecules in matter.

By applying these principles in connection with known conditions by which X-rays lead indirectly to action on a photographic plate, the authors of this remarkable work lead us along devious and wonderful paths, and considerations more or less similar to Newton's concept of "fits" give us new and surprising views of matter and of molecular structure.

The diagram which represents the molecular concept of naphthalene tetrachloride (*p.* 253) affords an example of one aspect of progress; while the X-ray spectra of fatty acids (plate viii. *p.* 172) affords another aspect, and the crystalline structure of the diamond as represented on *p.* 100 exemplifies a third aspect.

MINERAL RESOURCES OF SOUTHERN HSINKIANG (Chinese Turkestan).

Southern Hsinkiang is exceptionally rich in valuable minerals and oil, none of which are exploited on modern lines and some not exploited at all. The following are worked in the order of their importance:—Jade, gold, copper, oil and coal. Other deposits which are known to exist but which are not, so far as is known, worked at the present date are:—silver, lead, iron, antimony, sulphur and mica. The following particulars regarding the minerals worked are taken from the Report by H. M. Consul-General at Kashgar on the trade of Chinese Turkestan in 1922-23:—

Jade. Jade is found in the micaceous and horneblendic schists of the Kuen Lun Mountains, whence it is carried down in lumps and pebbles of varying size by the Karakash, Yurungkash and Keriya Rivers. The people of Khotan, Keriya and neighbouring villages recover the stone in considerable quantities from the river beds; formerly it was mined *in situ* at an almost inaccessible spot in the gorge of the Karakash south of Khotan, but the mine has not been worked for many years and its very existence is now forgotten locally. There is no longer the free market for the product of the river beds that there used to be; most of it is taken up at prices fixed by themselves by the Chinese officials, and lumps of first quality translucent green stone seldom or never come into the open market. The white and dull green jades cost little in the uncarved state, the value being in the carving, which is done by artists at Peking. This work is not and has never been done at Khotan itself, where the stone is only worked into simple articles such as beads, bangles, cups, etc.

Gold. "Placer" gold workings of considerable importance exist at several places, notably at Surghak on the Niya River, 45 miles east south-east of Keriya and at Kapa, 25 miles south of Keriya. There are also workings at Chugullak and Chapchand in the same neighbourhood; the high snowy range, part of the Kuen Lun system, at the foot of which these mines are situated, being known as the Altyn Tagh or "Golden Mountains." The mines are exploited in a primitive manner by the Chinese officials through local contractors, who slave-drive the miners to such an extent that being sent to work in the gold mines is a common form of punishment for criminals in the Khotan and Keriya districts. The Chinese frequently have trouble with the contractor and the output varies accordingly; in a good year as much as 900 lbs. of gold is produced by an average of 2,000 miners. Nuggets of a pound or more are frequently found. Gold "placers" are also worked at an extremely lonely and desert place called Ak-tagh in the Karakoram, eight days' march south of Yarkand. This place is so inaccessible that it can only be worked for two months in the early summer, after the snow has melted and before the summer floods have reached their height, and then the miners have to bring all their food and firewood with them. Owing to the lack of pumping plant the output of these workings, which are continually being flooded, is small; but the gold-sand is very rich and if worked properly would yield large profits. There are also undoubtedly gold deposits in other parts of the mountains to the south of Yarkand, but the people keep them secret in order to prevent the Chinese starting mines and forcing the local people to work them.

Copper. Extremely rich deposits of red, black and green copper ores, from which pure metallic copper is produced by one smelting only, exist on the Terek river in the foothills of the T'ien Shan to the north of Kashgar and at Kanjigan, west-north-west of Kashgar. The "mines" are mere scratchings, as the Chinese who exploit them do not know how to carry their shafts to any depth, but even so about 40,000 lbs. of the metal are produced annually and made into all kinds of utensils for the local market. Copper is also worked at Onbash on the Muzart river, 70 miles north-east of Aksu, while the ore is found near Kokya on the Yarkand-Ladakh road and in the Alai Mountains to the west of Kashgar. No one in Kashgaria has any idea of how to refine copper chemically.

OIL. The "Ferghana series" of oil-bearing strata extends into Kashgaria through Kanjigan, along the foot of the T'ien Shan, past Aksu and right up to Kuchar. The chief wells worked by the Chinese are at Kankjigan, Aksu and Kuchar; boring and chemical refining are alike unknown, the crude oil being scooped out of surface wells and holes. Even so, the strata are so rich that petrol, kerosene, machine oil, grease and mineral wax (ozokerit) of tolerable quality are all produced by means of primitive plant and used freely in the chief towns. Here again the exploitation and manufacture, such as they are, are kept carefully in their own hands by the Chinese. The chief refineries are those worked at Kashgar by the Titai (General Officer Commanding, Kashgaria) and at Aksu by the Magistrate.

COAL of fair quality, rich in coke, is found at Kanjigan, where shallow and primitive mines are worked by the Chinese. As only out-crops and weathered layers are mined, the coal is full of ash and is unsatisfactory for domestic use; but it would make an admirable fuel for metallurgical purposes. Coal exists at many other places in the province, but the only other mines worth mentioning in the southern part are near Aksu and in the Karatash Valley south of Yangi Hissar.

Beside the above minerals, the following are worked by the local Turkis and are always to be found in the bazaars: ozokerit (found in natural state near Kuchar and south of Yarkand; used extensively for candles); alum, sal ammoniac, gypsum. Good quality fireclay is found in the carboniferous strata and is extensively used by the natives in their smelting operations; it will be invaluable if and when the mineral resources of Southern Hsinkiang are ever properly worked. At the present the one idea of the local Chinese authorities seems to be to keep foreign enterprise out and exploit the minerals of the province for their own sole benefit.

GENERAL NOTES.

◆

NEW PROCESS FOR MAKING WOOL FUR.—A paragraph under this heading appeared in the *Journal* of March 16th, 1923, reporting a newly invented process from Western Australia, whereby certain kinds of fleece can be manufactured into a rich fur-like material of remarkable warmth and lightness. A number of enquiries were received, asking where specimens of the material could be obtained. At that time there were no samples in this country, but the inventor, Mrs. Mary E. Southern, has now brought some over to London, and a collar and muff are on view in the Australian Pavilion of the British Empire Exhibition at Wembley. The process of manufacture is original and interesting, and the material, which should be obtainable in almost endless natural shades, appears to be as durable as it is attractive in appearance.

EMPIRE MINING AND METALLURGICAL CONGRESS.—This Congress will be held at the British Empire Exhibition on June 3rd, 4th, 5th and 6th, 1924. The Congress has for its chief objects: (*a*) The discussion of papers dealing with the scientific, technical, and economic problems connected with the development of the mineral resources of the Empire, and the mining and metallurgical industries. (*b*) The constitution of an Empire Council of Mining and Metallurgical Engineering Institutions, whose principal functions would be: (1) To serve as an Organ of intercommunication between the co-operating institutions, and to promote the interests of the professions and industries. (2) To create and maintain throughout the Empire a high standard of technical efficiency and professional status. (3) To convene successive Congresses within the Empire. (4) To establish, if it be found after discussion by the Empire Council and the co-operating Institutions to be necessary or desirable, a Register of British Mining and Metallurgical Engineers.

JACOBITE WINE GLASSES.—The large collection of English glass at present on exhibition in the Loan Court at the Victoria and Albert Museum has been further augmented by a fine collection of about fifty pieces lent by Mr. C. Kirkby Mason. These pieces (including two rare decanters) consist exclusively of glasses engraved with portraits, mottoes and emblems commemorative of the Jacobite cause, and date from the middle and second half of the 18th century. There are several unique specimens, and the collection as a whole worthily represents, not only the finest period of English glass-making, but also an interesting phase of English history.

MEETINGS OF THE SOCIETY.

◆

ORDINARY MEETINGS.

WEDNESDAYS:—

MAY 21, at 8 p.m.—(Trueman Wood Lecture.) **SIR WILLIAM J. POPE**, K.B.E., D.Sc., F.R.S., Professor of Chemistry in the University of Cambridge, "The Outlook in Chemistry." **SIR HERBERT JACKSON**, K.B.E., F.R.S., will preside.

MAY 28 (at 4.30 p.m.)—**MRS. ARTHUR MCGRATH** (Rosita Forbes), "The Position of the Arabs in Art and Literature." **LORD ASKWITH**, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

MONDAY JUNE 30, at 4.30 o'clock.—**J. C. FRENCH**, I.C.S. "The Art of the Pāl Empire in Bengal." **THE RIGHT HON. THE EARL OF RONALDSHAY**, G.C.S.I., G.C.I.E., will preside.

DOMINIONS AND COLONIES SECTION.

TUESDAY, MAY 27, at 4.30 o'clock.—**C. GILBERT CULLIS**, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "A Sketch of the Geology and Mineral Resources of Cyprus." **DR. J. W. EVANS**, C.B.E., F.R.S., President of the Geological Society, will preside.

MONDAY, JUNE 2, at 5 o'clock.—**THE RT. HON. SIR FREDERICK LUGARD**. G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member, Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates." **THE RT. HON. VISCOUNT MILNER**, K.G., G.C.B., G.C.M.G., will preside.

MONDAY, JUNE 16, at 4.30 o'clock.—**C. V. CORLESS**, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, MAY 19 Geographical Society, 135, New Bond Street, W., 8.30 p.m. Ahmed Hassanein Bey, "Through Kufra to Darfur."
British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. S. Perks, "London Town Planning Schemes—1666 and After."
University of London, University College, Gower Street, W.C., 5 p.m. Prof. G. D. Hicks, "Kant's Theory of Sublimity and Beauty." (Lecture II.)
5.30 p.m. Prof. Sir Flinders Petrie, "Recent Discoveries in Egyptology."
At King's College, Strand, W.C., 5.30 p.m. Prof. T. H. Bryce, "The Development of the Human Embryo up to the Appearance of the Primitive Segments." (Lecture III.)
University Extension Lectures, Gresham College, Basinghall Street, E.C., 6.15 p.m. Dr. A. Compton-Rickett, "Personal Forces in Modern Literature." (Lecture III.) Eugene O'Neill.

TUESDAY, MAY 20 Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.15 p.m. Dr. Major Greenwood, "The Mortality Statistics of Sweden and England and Wales—an International Comparison."
Anthropological Institute, at the Royal Society, Burlington House, Piccadilly, W., 8.15 p.m. Mr. S. Routledge, "The Austrel Islands and Mangarera, S.E. Pacific."
Transport, Institute of, at the Institution of Electrical Engineers, Victoria Embankment, W.C., 5.30 p.m. Mr. F. Bullough, "The Scientific Preparation of Railway Time-Tables."
Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. J. Barcroft, "Effect of Altitude on Man." (Lecture IV.)
Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. H. Willford, "Some Methods and Results in Nature Photography."
University of London, King's College, Strand, W.C., 5.30 p.m. Mr. D. Subotü, "The Second Reign of Prince Milos" (1858—1860).
5.30 p.m. Prof. H. Bryce, "The Development of the Human Embryo up to the Appearance of the Primitive Segments." (Lecture IV.)
At the Imperial College of Science, South Kensington, S.W., 5.15 p.m. Dr. W. G. Miller, "The Pre-Cambrian—with special reference to that of Ontario." (Lecture II.)

WEDNESDAY, MAY 21 Meteorological Society, 49, Cromwell-road, S.W., 5 p.m.
Literature, Royal Society of, 2, Bloomsbury Square, W.C., 5 p.m. Anniversary Meeting.
University of London, University College, Gower Street, W.C., 3 p.m. Prof. E. G. Gardner, "Problems of the Inferno of Dante." (Lecture I.)
At King's College, Strand, W.C., 5.30 p.m. Prof. L. T. Hobhouse, "Religions of the Empire."
At the Imperial College of Science, South Kensington, S.W., 5.15 p.m. Prof. Dr. P. Zeeman, "The Optical Effects of Motion."

THURSDAY, MAY 22 British Science Guild, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 2 30 p.m. Annual Meeting.
London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Rev. A. G. B. West, "The Spirit of London."
Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.
Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.
Structural Engineers, Institution of, 296, Vauxhall Bridge Road, S.W., 7 30 p.m. Mr. B. C. Davies, "Economics in Concrete."
Royal Institution, Albemarle Street, W., 5.15 p.m. Dr. E. V. Appleton, "Atmospheric Interference in Wireless Telegraphy." (Lecture II.)
University of London, King's College, Strand, W.C., 5.30 p.m. The Rt. Rev. the Lord Bishop of Manchester, "The Philosophical Pre-Suppositions of the Doctrine of the Incarnation."
5.30 p.m. Prof. A. J. Toynbee, "Outlines of Byzantine, near Eastern and Modern Greek History" (378—1841 A.D.). (Lecture V.)
5.30 p.m. Mr. A. Del Re, "English Influences in Italian Literature during the XVIII. Century." (Lecture III.)
Linnean Society, Burlington House, Piccadilly, W., 5 p.m. Anniversary Meeting.
Constructive Birth Control, Essex Hall, Essex Street, Strand, 8 p.m. Mr. H. G. Cannon, "Reduction in number of offspring of Animals as they ascend the Ladder of Evolution."

FRIDAY, MAY 23 Transport, Institute of. L.M. and S.R. Offices, Hunt's Bank, Manchester (N. Western Section). Annual Meeting.
Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.
Royal Institution, Albemarle Street, W., 9 p.m. Dr. Andrew Balfour, "Historical Aspects of Malaria."
Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. W. L. Rea, "Wanderings in Northern Italy."
University of London, University College, Gower Street, W.C., 5.30 p.m. Miss M. S. West, "The Old Testament." (Lecture III.)
At King's College, Strand, W.C., 5.30 p.m. Dr. E. R. Bevan, "Ancient Ghost Stories and Theories about Ghosts."

SATURDAY, MAY 24 . Royal Institution, Albemarle Street, W., 3 p.m. Dr. W. G. Alcock, "Musical Ornamentation."

Journal of the Royal Society of Arts.

No. 3,731. VOL. LXXII.

FRIDAY, MAY 23, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

TUESDAY, MAY 27th, at 4.30 o'clock. (Dominions and Colonies Section.)—C. GILBERT CULLIS, D.SC., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "The Geology and Mineral Resources of Cyprus." DR. J. W. EVANS, C.B.E., F.R.S., President of the Geological Society, will preside.

WEDNESDAY, MAY 28TH, at 4.30 p.m. (Ordinary Meeting.)——MRS. ARTHUR McGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature." LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

A meeting of the Council was held on MONDAY, MAY 12th. Present:— Lord Askwith, K.C.B., K.C., D.C.L., in the Chair; Sir Thomas J. Bennett, C.I.E.; Lord Blyth; A. Chaston Chapman, F.R.S.; Mr. Edward Dent, M.A.; Mr. P. M. Evans, M.A., LL.D.; Sir Robert Hadfield, Bt., D.Sc., D.Met., F.R.S.; Rear-Admiral James de Courcy Hamilton, M.V.O.; Sir Thomas Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.; Sir Herbert Jackson, K.B.E., F.R.S.; Major Sir Humphrey Leggett, D.S.O., R.E.; Sir Philip Magnus, Bt.; Mr. Alan A. Campbell Swinton, F.R.S.; Sir George Sutton, Bt.; Mr. Carmichael Thomas; Dr. J. Augustus Voelcker, M.A., Ph.D.; Sir Frank Warner, K.B.E.; Sir Philip Watts, K.C.B., LL.D., F.R.S.; and Sir Alfred Yarrow, Bt., M.Inst.C.E., F.R.S.; with Mr. G. K. Menzies, M.A. (Secretary of the Society) and Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

The question of the award of the Albert Medal for 1924 was further considered.

Preparation of the balloting list for the new Council was begun.

The entries for the June Section of the Examinations was reported. These are 43,838. The entries in April were 27,273, making a total of 71,111, as compared with 68,251 in 1923, an increase of 2,860.

Sir Thomas Holland, F.R.S., was appointed to represent the Society at the Franklin Institute Centenary Celebrations, and Major Percy A. MacMahon, F.R.S., to represent the Society at the International Mathematical Congress, Ontario.

Other formal business was transacted.

TWENTY-FIRST ORDINARY MEETING.

WEDNESDAY, MAY 14th, 1924; MR. ERNEST POLAND, Vice-President of the London Fur Trade Association, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Angle, Edward John, M.D., B.Sc., A.M., Nebraska, U.S.A.
Birch, Prof. T. Bruce, A.M., Ph.D., Springfield, Ohio, U.S.A.
Else, J., R.B.S., Nottingham.
Hansard, Colonel Arthur Clifton, C.M.G., London.
Henderson, Francis, J.P., Tunbridge Wells, Kent.
Hertz, Jacob, London.
Holdengarde, Theodore Albert Edward, Bulawayo, Rhodesia, S. Africa.
MacGallavry, Robert, Java, Netherlands East Indies.
Shehata, Nasif Girgio, Birmingham.

The following candidates were duly elected Fellows of the Society:—

Archibald, John Smith, Montreal, Canada.
d'Erlanger, Baron Emile Beaumont, London.
Drake, William Allen, Dayton, Ohio, U.S.A.
Flavelle, Sir Joseph Wesley, Bt., Toronto, Canada.
Fleming, Alfred, Southsea, Hants.
Garrigues, H., Copenhagen, Denmark.
Hodges, Gordon, London.
Izod, Edwin Gilbert, Johannesburg, Transvaal, South Africa.
Lynn, Scott, Mem.A.I.E.E., Toronto, Canada.
Nicholson, Reginald, M.B.E., Midhurst, Sussex.

Rai, H., Indore, Central India.
Whitby, Thomas Broom, Nottingham.
Williams, Frederic N., Shreveport, Louisiana, U.S.A.

A paper on "Furs and the Fur Trade" was read by Mr. F. C. Ingrams, President of the London Fur Trade Association.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 9th, 1924.

Sir Frank Dyson, LL.D., F.R.S., Astronomer Royal, in the Chair.

The Secretary said that Professor Vernon Boys, who was to have taken the Chair that night, was, unfortunately, unwell. The Society, however, had succeeded in securing the attendance of the Astronomer Royal, who had undertaken to fill the Chair at very short notice.

The Chairman, in introducing the lecturer, said he was sure everybody would be extremely sorry at Professor Boys's absence. Professor Boys was the prince of experimenters. No one in the world was more capable of making beautiful and delicate experiments, and the audience, no doubt, would have liked to have his appreciation of Mr. Hope-Jones's clock. What Professor Boys would have had to say about it would have been of the greatest value and interest.

Personally, he was very pleased to take the Chair that night, although he might as well confess at once that his knowledge of the intricacies of clocks was very small. As an astronomer, however, he was much interested in the making of clocks, but he was afraid that he simply trusted to others to supply him with a clock, and then saw how it went. Astronomers had used clocks for 250 years. Up to that period they had got the time by observations of the altitudes of stars. Just before coming to the meeting he had looked up the record of Bradley's clock, and he had been very surprised to find how well it had gone. Its date was about 1755. It had gone between June 1st and August 31st with its rate changing only from a second to a second-and-a-half a day, and its rate changed from one day to another by about a tenth of a second. In recent times, a very great improvement in clocks had been made years ago by Riefler, but from what he had seen of the author's clock at Edinburgh, it seemed to be far ahead of Riefler's clock, and without more ado he would ask Mr. Hope-Jones to state how it had been done.

The paper read was:—

THE FREE PENDULUM.

By F. Hope-Jones, M.I.E.E.

Exact measurement is the basis of scientific advance. The new Journal of Scientific Instruments recently established by various London Societies, has adopted this axiom as its watchword, and it is a truth which the Royal Society of Arts has always recognised. Last year's series of Cantor Lectures was devoted to precise measurements of length, and, whilst I can make no pretensions to such an exhaustive and brilliant treatise as that of Mr. Sears, the subject I am dealing with this evening is very closely akin to it, being the precise measurement of time.

Just 100 years ago Parliament made provision for restoring the standard yard, should it be lost or damaged, enacting that in this event a new standard should be made, bearing the same proportion to a pendulum beating seconds of Mean Time, in a vacuum at London and at sea level as 36 inches bears to 39.14 inches. Within ten years thereafter the Houses of Parliament were burnt down and the British standard destroyed, but the reference to the pendulum was found to be impracticable.

Thanks to the refinements of modern methods of measurement, we are able to satisfy ourselves that our national standards of length, when compared with one another from time to time, agree to within one part in two million, but that is no proof of their stability, as they may both be changing equally and imperceptibly. It is therefore highly desirable to find some "natural" or external standard as a basis of reference. Mr. Sears has put forward a proposal to refer his standards of length to the length of an Elinvar rod, which, when caused to vibrate longitudinally makes a definite number of vibrations per day. The success or failure of this method depends upon the continued constancy of the *modulus of elasticity* of the rod, its mass and its length.

If we look upon Mr. Sear's vibrating rod as a clock, it may be said that *ultimately* the constancy of its rate depends on the constancy of its *elasticity*, whereas the constancy of the rate of the ordinary pendulum clock *ultimately* depends on the constancy of the value of *gravity.* Which of the two has the higher order of constancy remains to be proved.

We, at any rate, are chiefly concerned with the type of clock which depends on gravity, and our efforts have been directed to eliminate the effect of the various subsidiary influences, and to make the timekeeping of our clock, as Professor Sampson, the Astronomer Royal of Scotland, has put it, "as steady as the length of a rod," and dependent only on gravity. As we have succeeded in measuring time for considerable periods to within 100th of a second per day, or one part in 8 million of the time measured, representing a change of length of one part in 4 million of a pendulum rod beating seconds, it would appear that we have reached the limit of accuracy *if so defined*, and if we can maintain such a constant rate indefinitely—a very different thing to doing it for a month or two.

It may be asked, how do we know that we have achieved this rate ? There is no standard in existence with which you can compare your clock to such a degree of accuracy from day to day, but there is, of course an ultimate standard of time based upon the rotation of the earth, and ascertained by transit observations of fixed stars. The methods of observing them, however, are comparatively crude. The transit circle observations, with automatic or semi-automatic travelling cross wire, give only a coarse and approximate reading, compared with the way in which we now record the performances of clocks. At the Edinburgh Observatory the recording instruments comprise an oscillograph and a cinematograph film with continuous motion used as a chronograph, which easily enables the clocks in the Observatory to record their beats to an accuracy of 1/1000th of a second, and they are commonly so recorded every day.

You cannot use stellar observations for a day to day test. When two clocks keep together to within 1/100th of a second for considerable periods, and the telescope frequently makes them wrong—sometimes to the extent of ± 1/10th of a second—one knows it is the transit observations which are at fault and not the clock. Such observations being admittedly 100 times as rough as the clock observations, you rate the clock from a long series of daily transits, of which you may require to take 100 to establish a straight datum line.

But in this matter Astronomers have had valuable assistance from wireless telegraphy, which now enables them to compare with one another the times of distant Observatories as determined by transit observation. This is done by means of the Rhythmic Signals or Time Vernier, first established by General Ferrié at the Eiffel Tower in 1911, and it enables distant clocks to be compared to an accuracy of 1/100th of a second. It has revealed some rather disturbing discrepancies, unaccountable and irregular; differences amounting to as much as ½ of a second being frequently observed. This remarkable service has thus demonstrated the need for improvement in clocks of the highest order, and will doubtless exercise a powerful influence in that direction, just as on a lower plane the broadcasting of time signals is tuning up the watch and clockmaking profession, and improving the punctuality of the community.

I have said enough to remind you of the importance of precise time measurement, and to give you some idea of the degree of accuracy now demanded by the advance of science. It is in the nature of a race; accuracy of means of comparison has outstripped instrumental accuracy of both clocks and telescopes; and an effort is now being made to bring the clock up to scratch. Improvement is long overdue, for there has been no really important advance in horology for nearly 200 years, that is to say, since the days of Graham, Harrison, Mudge and Arnold, with the exception of Riefler, of Munich, of whom more anon.

Since 1895, when I read my first Paper in London at the British Horological Institute, I have approached this subject from a very definite point of view. My aim throughout has been to relieve the clock, or its pendulum,

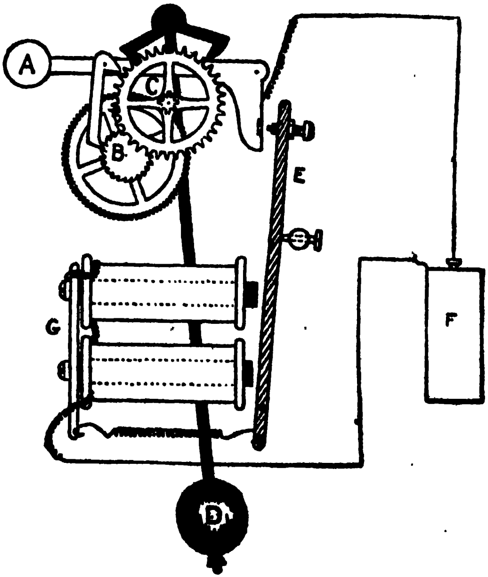

FIG. 1. The "Synchronome" Remontoire.

of interference. The first objects of attack were those innumerable contact applications intended to make clocks self-winding. In so far as energy was robbed from the clock, and was obtained at the expense of the time-keeping function, they were vicious, and had made electric clocks a byword for unreliability. That matter was successfully disposed of by using a cranked lever to drive the clock, lifting or resetting it by the armature of an electro-magnet in the manner shown in Fig. 1.

The weighted lever A as it falls turns the wheels B and C and keeps the pendulum D swinging. When it reaches the armature E the circuit of the battery F is closed, and the electro magnet G replaces the weight by throwing it up on to the next tooth of the ratchet B. The feature of this arrangement was that no energy was taken from the clock, yet inasmuch as the whole of the driving force was transmitted through the surfaces of the contact, its reliability was assured.

That brought us, at the beginning of the century, to the point of being able to say that clocks were no worse for being electrically re-wound, in fact, as the rewinding was frequent and the drive constant, they were perhaps a little better. Incidentally the remontoire action constituted an excellent switch for the operation of circuits of electrical impulse dials, but that has nothing to do with us now, excepting only this, that it exercised its influence towards breaking away from the stereotyped forms of escapement. The vision of the clockmaker had been bounded for a century or more by escapements. Pin wheel, anchor, half dead-beat, dead-beat and gravity, all had been analysed and tried out to the very end. The Graham dead-beat emerged as the best for precision timekeeping.

The limit of accuracy had apparently been attained; an impasse had been reached, and there was no room for further theorising or experimenting.

It appears to have been taken for granted from the earliest days of clockmaking, that it was desirable, or perhaps necessary, for the impulse to be imparted to the pendulum at every swing. In explaining how it has been found possible to free the pendulum altogether, I shall show you that it is neither desirable nor necessary to give frequent impulses, and that electrical time circuits of half-minute periodicity have contributed materially to the breaking away from a hide-bound custom.

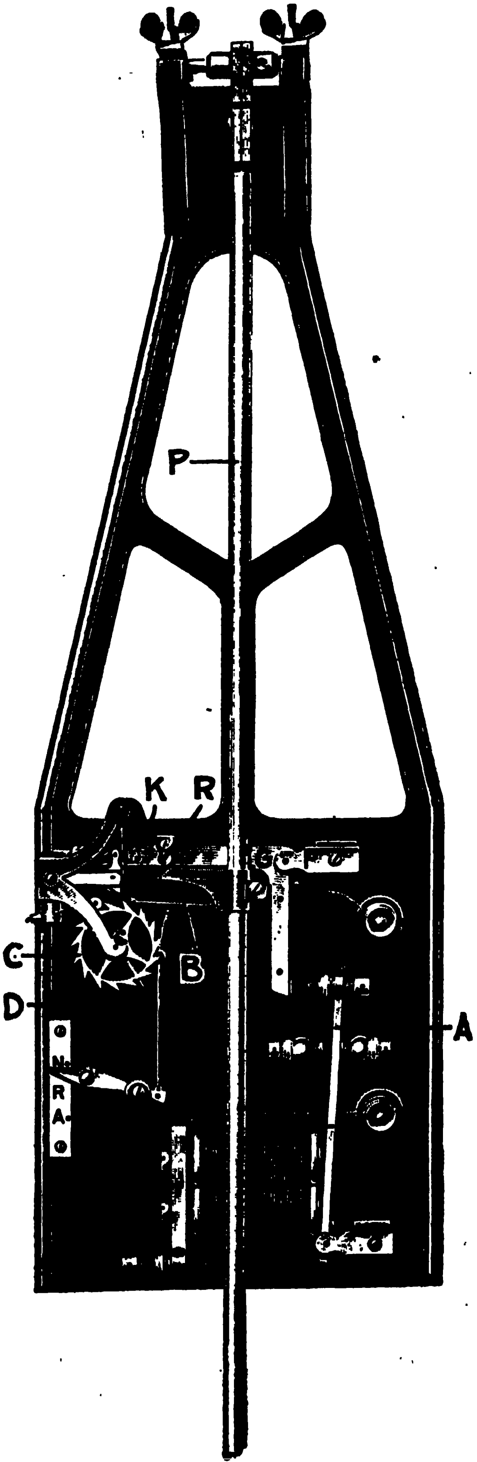

Fig. 2. The "Synchronome" Switch.

There are, of course, two sources of interference with the natural swing of a pendulum; firstly—the very word "escapement" implies it—the releasing of stored power in small instalments; the energy expended by the pendulum in that act of release may be variable; secondly, the impulse itself when given must necessarily interfere to some extent with its free swing.

The first can be dispensed with altogether; the second may be rendered innocuous by imparting it to the pendulum when the latter is passing through its zero position.

To understand how this is done, it is necessary in the first place to master thoroughly the action of this simple electro-mechanical device known as the Synchronome switch, illustrated in Fig. 2. It is a combination of a pendulum and a switch. The pendulum tells the switch when to work (usually every half-minute), and the switch imparts an impulse to the pendulum when it falls.

The switch consists of two moving parts; the right-angled lever G and the magnet armature A resting against stop E. The right-angled lever G is centred at F and normally supported on the spring catch K. Once every half-minute the lever is released, and, after giving impulse to the pendulum, makes contact with the armature, with the result that an electric current passes through magnet M, which accordingly attracts armature A, and throws the lever G up on to its catch again. A number of electrical impulse dials are usually included in this circuit.

If the current is insufficient the armature does not move, and the circuit remains closed until the pendulum on its return swing comes to the assistance of the magnet. This abnormal increase in the time of contact is utilised to give a visible or audible warning of the impending failure of the battery, by lighting a lamp or ringing a bell. The pendulum will usually continue to operate under battery warning conditions for some days, and only ceases to do so when the current has got so low that magnet plays practically no part in the lifting of the lever.

The pendulum releases the switch by means of the 15T wheel C and the vane D, which engages with the catch K at each revolution. The hook B, pivoted upon the pendulum P, rotates this wheel one tooth at a time once every thirty seconds. L is a backstop.

Impulse is given to the pendulum by the little roller R, attached to the gravity arm, running down the curved end of the pallet J fixed to the pendulum. At the moment of release the sloped face of the pallet has just *not* passed under the roller, and the pendulum has just not reached its mid position. Thus the impulse is given while the pendulum is passing through its mid or central position, and the pendulum is quite free at the ends of its swing. The escapement is, therefore, not only detached, but operates at zero, and thus fulfils the horologist's ideal.

The shape of the impulse face of the pallet J has been determined mathematically, so that the impulse commences very gradually, increases to its maximum at zero and then decreases in an identical manner.

When the switch is used to operate circuits of electrical impulse dials it is called a master clock, and is designed so that its minimum operating current is more than that required by any dial or other instrument in the circuit, and, as all the operating magnets are in series, it follows that the circuit has considerable self-induction, and that the current takes some hundredths of a second to attain its full value. Consequently, it is impossible for the switch to operate without supplying sufficient energy to the various dials to propel them.

I demonstrated this by oscillographs in my 1910 Paper, before the Institution of Electrical Engineers, one of which is reproduced here. It may be described as a photograph of one of the Synchronome half-minute impulses. The small depression

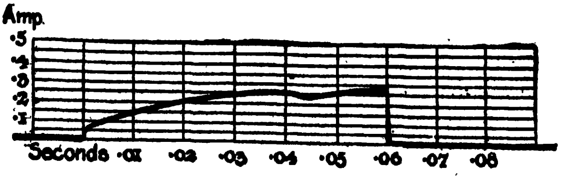

FIG. 3. Oscillograph of Synchronome impulse.

between .04 and .05 seconds represents the operation of the dials, and the area enclosed between the curve and the base line represents the quantity of electricity consumed per impulse, which in this case is .012 coulombs, and, since the impulses are repeated every half-minute, this equals about 3½ amp. hours per annum. As each dial requires about 1½ volts across its terminals, the annual consumption of energy per dial is about 5¼ watt hours.

As the voltage of the battery drops, the duration of the contact increases, the energy consumed remaining practically unaltered; consequently a very considerable drop must take place before the switch commences to indicate failing battery.

The oscillograph test, which will infallibly reveal the slightest intermittency or raggedness of impulse, demonstrates the perfect cleanliness and precision of the make and break, cardinal virtues not easily obtained.

It will be observed that the energy devoted to making a good and reliable contact is considerable, but it is not taken from the pendulum. It comes from the electro magnet, being, in fact, the whole of the energy developed by that magnet, and it is all mechanically transmitted through the surfaces of the contact.

All that the pendulum has to do is to count out the half-minutes (by pulling round an idle wheel), and to release the catch supporting the gravity arm.

If only these two duties could be done for it, then we could truthfully call it a free pendulum, subject to no interference whatever, excepting only that which is inevitable and inherent in the act of impelling it. Is this possible? For long enough it seemed so impossible that no one even asked for it. After all, we can hardly blame clockmakers for not inventing an escapement which does not escape.

The idea is to employ a subsidiary instrument—some extraneous mechanism—charged with the duty of releasing the gravity arm, and that this instrument should be dominated or controlled in some way, so far as time-keeping goes, by the free pendulum. Thus, if perfect phase synchronisation could be maintained between two pendulums, one could be employed to perform the duty for the other.

At first view it is not easy for a person of average intelligence, even though he may have the mechanical instinct and be well versed in clock escapements, to understand how it is possible for a free pendulum, which is not allowed to touch anything, or to do any work whatever, to communicate synchronising impulses to another. In saying "Not allowed to touch anything" I was not quite correct, for it is touched by something, viz., a falling gravity lever, which imparts an impulse to it. Advantage is taken of the fact that the exact point of time at which the impulse terminates is determined by the pendulum, and, the impulse being over, the gravity arm in its further fall is employed to give the synchronising signal. It is with a view to simplifying this explanation that I have had to tax your patience to acquire a thorough understanding of the Synchronome switch.

Refer to Fig. 2, and consider for a moment what determines the precise instant at which contact between G and A occurs. It is, and always must be, dictated by the pendulum in its passage from left to right, after receiving the impulse. Assume for a moment that we have found some means of releasing the gravity arm G without the aid of hook B, wheel C and vane D, then let us establish our free pendulum and apply such a gravity arm catch and magnet to it. The gravity arm being released by some means, delivers its impulse to the pendulum, and the resetting of it (in other words, the remontoire or switching operation) will take place, as we have seen at a point of time dictated by the free pendulum itself.

Obviously, therefore, we have in this switching operation a synchronising signal of absolute precision, obtained from the free pendulum without affecting it in any way, and with regard to the impulse which is the immediate preceding cause of the operation, it only affects the free pendulum in so far as any impulse not absolutely concentrated as a blow delivered upon it when passing through its zero point, may rank as a possible disturbance to its natural period of vibration.

The diagram, Fig. 4, in which the same reference letters are used as in Fig. 2, shews the arrangement and inter-connection of the two clocks. It will, of course, be understood that in the free pendulum the catch K, which holds up the impulse lever, is released by an electro magnet at the moment the impulse pallet reaches precisely the right position. This magnet (which substitutes the count wheel and releasing mechanism of the standard switch movement)

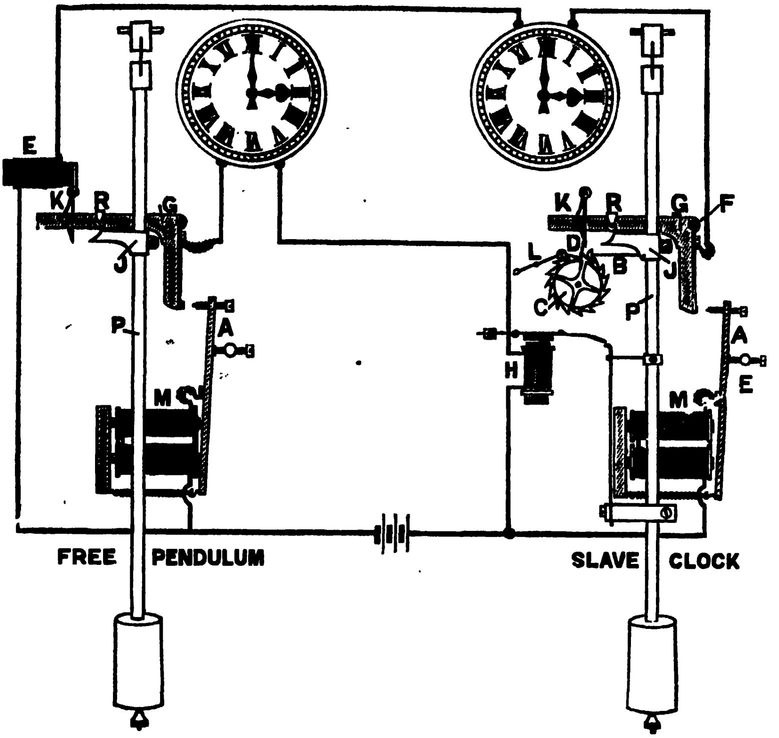

FIG. 4. Circuit diagram of Free Pendulum and Slave Clock.

is connected in the remontoire circuit of the slave, while the slave is synchronised through the agency of another electro magnet connected in the remontoire circuit of the Free Pendulum.

Just as the remontoire of the free pendulum operates the synchronising magnet on the slave every half-minute, so the remontoire of the slave operates the releasing magnet of the free pendulum's gravity arm every half-minute, and the effect is that one pendulum measures time and does no work, whilst the slave does all the work and has its precise timing done for it, a very satisfactory mutual arrangement.

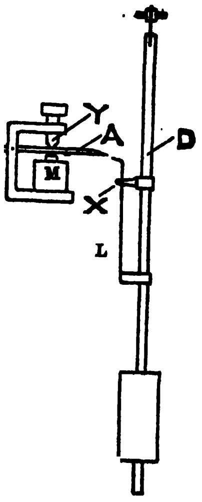

FIG. 5. The "hit or miss" Synchroniser.

The synchronisation of the slave pendulum is achieved by means of the device illustrated in Fig. 5.

The synchronising electro magnet M is fixed adjacent to the slave pendulum D, so that its armature A is horizontal, and will, when attracted, just engage with the upper end of the springing vertical lever L attached to the slave pendulum, as the latter passes through its mid position, the engagement only being possible when the pendulum is swinging from right to left.

When this engagement takes place the continued movement of the pendulum bends the springing lever L and calls into play a force which assists gravity, and consequently accelerates that particular half swing by a small fraction of the period of vibration. X and Y are stops against which L and A normally rest.

The slave is given a small losing rate of about 6 seconds a day compared to the master, and is started up so that when swinging from right to left the operation of magnet M by the remontoire contact of the master pendulum movement is just too late for A and L to engage. Then, as a result of the losing rate, the phase difference of the two pendulums will gradually decrease until engagement finally takes place, with a consequent advancement of the phase of the slave corresponding to the quickening action of the spring. As this quickening action is arranged to be about twice as great as the amount lost by the slave during the interval in which it is undisturbed, it follows that at the next impulse the slave will not have dropped back quite enough to permit engagement by the electro magnet and a miss will occur; by the end of the next half-minute, however, the phase difference will be approximately the same as when the initial engagement took place, and a second engagement will ensue with a corresponding quickening.

This cycle of operations will obviously continue indefinitely, and the phase difference between the master and slave will not be allowed to vary by more than plus or minus the advancement produced by one operation of the spring. A losing rate of 6 seconds per day equals 1/480th of a second per half-minute, so that the quickening action of the spring need not exceed 1/240th of a second, and the phase difference of the two pendulums will never exceed plus or minus this amount. As long as the losing rate of the slave relative to the master does not increase to more than 12 seconds per day, nor decrease to less than zero, it will be held in phase with the master, and it will be agreed that the above limits of rate are amply sufficient to warrant the statement that the control of the slave by the master is complete.

It should be mentioned that the impulse roller and pallet are arranged in the master, or free pendulum, somewhat differently from that shown by the diagram Fig. 4, and the drawing Fig. 2, in order that the termination of the impulse may be independent of the drop of the lever, and dependent only on gravity and the arc of the pendulum.

Having thus relieved the pendulum of the last vestige of its duty, let us now consider the extent to which the impulses we impart to it are likely to interfere with its natural period of vibration. They are, of course, constant in value—uniform weight falling uniform distance. They are concentrated as far as possible at the centre of its path where its velocity is greatest. If this concentration were complete, the interference would not affect its natural period of vibration at all. If the duration of each impulse is about the 1/10th part of a second, and occurs only once in each half-minute, it represents 1/300th part of the time measured. Compare this with existing clock escapements, where the duration of the disturbance is either continuous or of the order of 50 per cent., or one second out of every two.

Nevertheless, "impulsing" is the one source of possible disturbance, and must be reduced to the absolute minimum. With that object and also with a view to cutting out the whole set of complex considerations involved in variation of air density, we proceed to exhaust the case from the normal of 760 mm. to about 30 mm. of mercury, by enclosing the whole free pendulum in an airtight case and pumping it out.

This reduction in pressure reduces the pendulum friction practically to that of the flexing of the suspension spring, and enables the normal arc to be maintained with an impulse lever of about 1/5th of the weight that would be required had the air been left in the case at atmospheric pressure. An arc of 100 minutes is maintained by a weight of .43 grammes falling 2.0 millimetres once every half-minute, the equivalent of about 1/8th foot-lb. per week. One seldom puts less than 50 foot-lbs. into the grandfather clock on Saturday night.

Of the stagnation of clock invention for nearly 200 years I have already spoken. The only other developments in that period which occur to me as worthy of mention are the Grimthorpe gravity escapement and Riefler's clock. The former has been a conspicuous success on turret clocks, for which it was designed, but it has not otherwise contributed to the science of accurate time measurement. The latter, on the other hand, has been adopted to an increasing extent in the world's observatories for the last thirty years, and held all the records until beaten at the Edinburgh Observatory last year. Briefly described, the top chops and trunnion are rocked on knife-edges coincident with the axis of suspension. By this means the impulse, derived from an escape wheel, is transmitted to the pendulum through the suspension spring. For a short distance beyond zero the spring is straight, the pendulum and trunnion swinging together on knife-edges, then the scape wheel delivers its impulse to the pallet and rocks the trunnion back a little, locking it there, and thus imparting its impulse through the spring.

Of course, it is not a free pendulum, though at first sight it appears to be, but the evils of interference are greatly reduced by avoiding all mechanical contact with the pendulum below the point of suspension.

The credit for the general idea of this division of labour by the employment of another clock must be accorded in the first place to Mr. R. J. Rudd, of Croydon, who accomplished it in the year 1898, but he hid his light under a bushel, and though he published a short description of it, it was never discovered by anyone competent to express the theory, and to turn his application of it to practical use.

A year or two later, in ignorance of Rudd's work, the late Sir David Gill attempted it in a clock for the Cape Town Observatory. He failed, but he was the first to speak of a "slave" clock. Mr. C. O. Bartrum, of Hampstead, in ignorance of both, patented a method of free pendulum and slave in 1913, and Father O'Leary, S.J., of Dublin, patented one in 1918. But I have not heard of any attempt to develop these inventions or to test their possibilities.

The principles involved appear to me to have been very inadequately dealt with by these inventors, and it is doubtful whether any of them appreciated fully the advantages inherent in this division of labour. Also, their electro-magnetic and/or mechanical apparatus usually transgresses one or other of what may now be laid down as two fundamental precepts, that just as the right time to impart impulse to a pendulum, with a view to minimum interference with its natural rate, is when it is passing through the centre or zero position at its maximum velocity, so the right time to synchronise it, i.e., to apply maximum interference to its natural rate, is when it is at the end of its swing and its velocity is at its lowest.

When once stated, these principles are perfectly obvious, but they have neither been realised nor expressed before, and I think there has been a tendency in our horological schools to adhere too closely to the text books on clock escapements, instead of looking beyond them with a wider vision and using them to illustrate great truths and natural laws.

These principles have not been easy to realise. The first, the delivery of impulse at zero, was achieved by Arnold and Earnshaw in the chronometer detent escapement 140 years ago. Many attempts have been made to apply the same method to a pendulum by those who appreciated the fact that none of the recognised clock escapements leave the pendulum free at the ends of its swing. Several people did it, but success being measured by adoption rather than by grace, the one to be mentioned is that of Sir Henry Cunynghame, who accomplished it with a mechanical escapement in 1906, which he assisted me to incorporate into the Synchronome System.

The second, however, the theory of synchronisation, is comparatively young as a problem, as it involves the use of electrical impulses, and this subject has been greatly neglected and misunderstood. A chronicle of attempts would reveal many blunders. One veritable stumbling block has been the confusion of indicated error and error of rate, two very different things. The synchroniser above described and the method of using it in combination with the Synchronome system to produce the free pendulum, is the invention of Mr. W. H. Shortt, M.Inst.C.E., who has been carrying out research work on high grade time-keeping since 1910. We had both been seeking a solution of this particular problem since I saw Rudd's clock at Croydon, and many methods were patiently tried out and discarded. I want to bear testimony to Mr. Shortt's ability in the conduct of patient and systematic research which has won for him the blue riband of our Turf, that is to say, a record of a higher degree of time measurement than any that has yet been achieved by man.

Synchronization involves two things, first a comparison, and then a correction. In Mr. Shortt's synchronizer the comparison is made when both pendula are at zero. It is then, immediately after impulse has been delivered, that the free pendulum transmits the comparing signal and it is when the slave clock is also at zero that it receives the signal and makes the decision as to whether or not acceleration is required. The correction, if it is made, takes place when the pendulum is on its half swing to the left, out and home, the action thus completely embracing the extremity of the swing which is where interference disturbs the pendulum most.

Before discussing the performance of the clock as recorded on the rate chart, let me sum up briefly those features to which I attribute the success achieved :—

There is NO INTERFERENCE with the pendulum's natural period of vibration, that is to say, it has nothing to do but to swing.

The IMPULSE is

(1) Uniform in value ;

(2) Delivered at or about zero ;

(3) Small in quantity ;

(4) Imparted occasionally, *i.e.*, at wide but regular intervals.

It is in a VACUUM which makes (3) and (4) possible, and eliminates all barometric considerations.

It is erected in a room kept at CONSTANT TEMPERATURE, because although the pendulum itself is compensated with the greatest thoroughness and care, the compensation can never be sufficient of itself.

It has only been possible to realise the

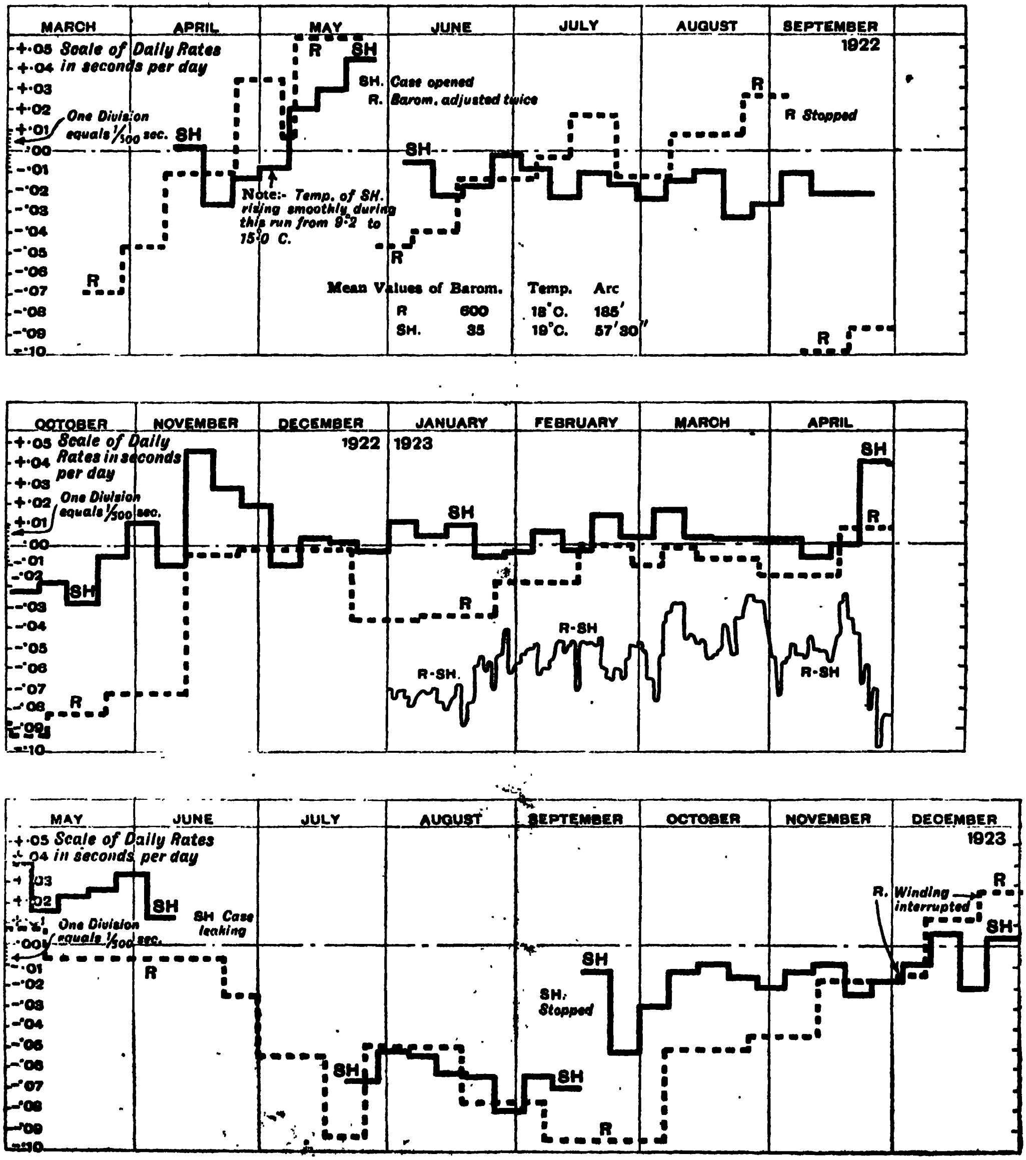

FIG. 6. Rates of Clocks Shortt (Synchronome) and Riefler, plotted from figures given in Professor Sampsons' Paper, R.Soc. Edin. January 14th, 1924.

above conditions by means of the Synchronome system, which had already met most of them and what is more important had proved its reliability up to the hilt. Not until a system has "worked out its salvation in fear and trembling" by public use in competition can it be trusted for the responsible work of an observatory. Astronomers cannot afford to waste time and money in experimenting and they would be particularly disinclined to do so in the case of electric clocks in whose name so many crimes have been committed.

The experience we have had of this clock since 1921, added to the obvious moral to be drawn from the success of Riefler's, has led me to the firm conviction that, for precision timekeeping, escapements are dead.

For this experience of the running of the clock we have had to thank Professor Sampson, the Astronomer Royal of Scotland.

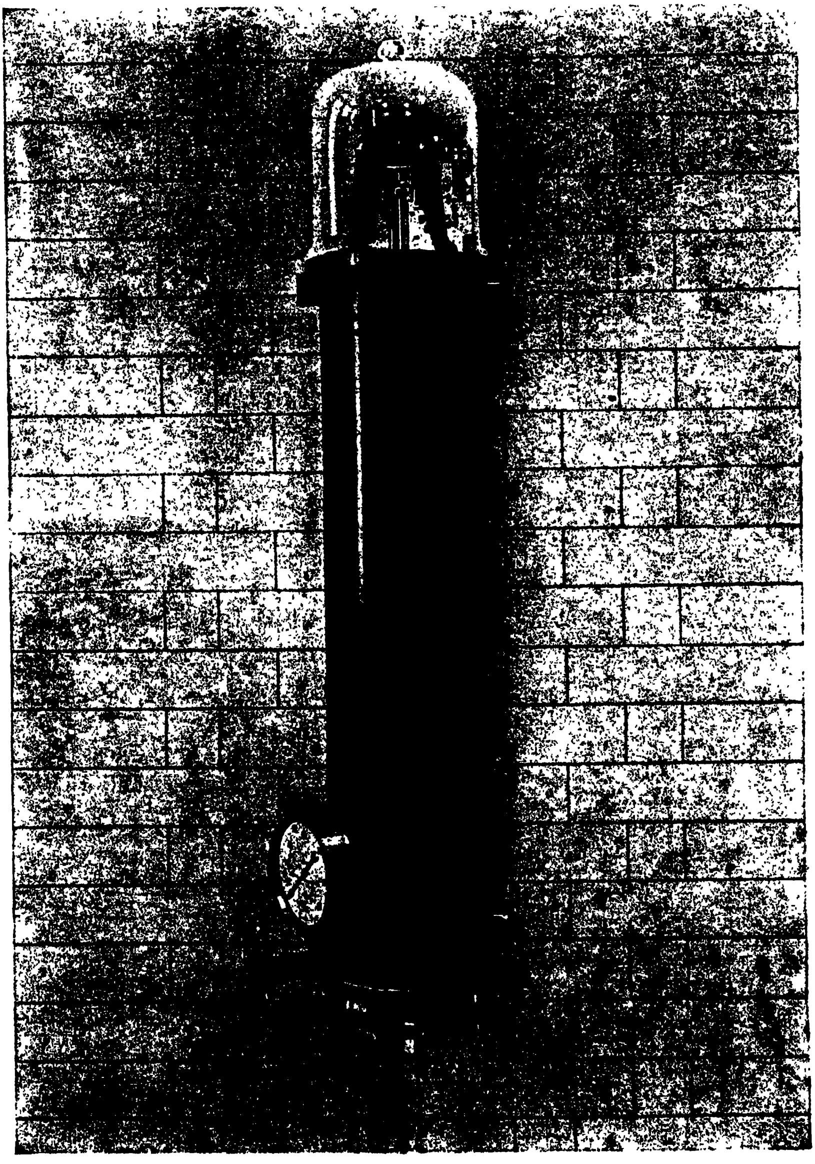

FIG. 7. Free Pendulum in Vacuo.

Since 1918 he has been contributing a series of papers to the Royal Society of Edinburgh on timekeeping. These and other contributions to the Proceedings of the Royal Astronomical Society in description of his special apparatus installed at the Edinburgh Observatory, have placed him in the forefront among the astronomers of the world as having specialized on accurate time measurement. His instruments at Edinburgh comprise an oscillograph and a cinematograph film with continuous motion used as a chronograph having the 10th parts of a second automatically recorded on the strip by means of a vibratory tongue over a window slit obscured and revealed at each vibration. With the use of a reading microscope the record is measured to the thousandth of a second. All the clock records appear on this strip.

I exhibit on the wall a chart (Fig. 6) produced with his permission from his last Royal Society of Edinburgh Paper. On it are plotted the rates of the Free Pendulum in red (black line) and of Riefler No. 258 in blue (dotted line). This particular Riefler has acquired some fame as probably the best ever produced by that firm. It is, of course, far superior to the best Graham dead beat escapement clock. I must here emphasise the unusual scale upon which the rate chart is drawn. If the horizontal divisions had been made to represent seconds as is customary, the curve would be so flat as to lose all interest—as flat as ditch water. It is doubtful if you could see any deviation from the zero line. And even if we multiplied the vertical scale by 10, so that each division represented a 10th of a second, it would still be too small a scale to express the facts clearly; the curve would lie entirely within one division. So we multiply by 10 again, using widely spaced horizontal lines, each space between them representing 1,000th of a second.

Owing to imperfections of transit observations, the problem of clock comparison on this high plane of precision is an exceedingly difficult one. Professor Sampson expresses the problem as follows:—"Given a number of clocks, A, B, C, . . . compared regularly, frequently, and accurately with one another, and compared also at irregular intervals, sometimes entailing long gaps, with the much rougher final stellar standard, to ascertain precisely what is happening in any interval." Professor Sampson treats the problem in this way: "The simplest plan, and that which I have taken, is to adopt one clock as director. The errors which are indicated by stellar observation for the director are charted just as they are observed, on every practicable night, without any smoothing whatever. Against these are also set the relative going of the director and each of the other clocks as shown by the microchronograph. The former chart may often run as a set of improbable zigzags. The latter will indicate reliably all sharp changes of relative rate that actually occur."

This method is open to the objection that if one of the other clocks was actually going better than the director, it does not get justice done to it, but is debited with the director's faults. Professor Sampson gives several instances of this, and I need hardly say that I believe our rate to be steady, that our line, to be truthful, should be a straight one and that the variations are the other fellow's; further, that it will so be proved when the free pendulum is elevated to the position of the director in the Edinburgh Observatory.

Now a few words with regard to nomenclature. New inventions require new names; the inventor coins them and their currency depends upon their utility. I have coined one, the Synchronome Switch, because it seemed to me to be a fundamental device possessing a number of distinctive qualities—a device which is likely to be used in different ways for different purposes; therefore, a single word to express it and its inherent virtues will be a convenience.

The word Slave, first used in this connection by the late Sir David Gill, is obviously appropriate as applied to the pendulum synchronously coupled to the Free Pendulum to perform the releasing function for it. This might lead one to speak of the Free Pendulum as the Master, but it must not be forgotten that what we now use as a Slave has been customarily regarded as a Master Clock, and will still remain so in so far as it is a transmitter of electrical impulses for the purpose of operating circuits of electrical impulse dials. When it is so used perhaps the term "Transmitting Slave" will be more appropriate than Master Clock.

Any number of transmitters can be controlled by a Free Pendulum and there is absolutely no limit to the contact making and switching operations which a Slave may perform without affecting the Free Pendulum even indirectly. A slave clock will operate

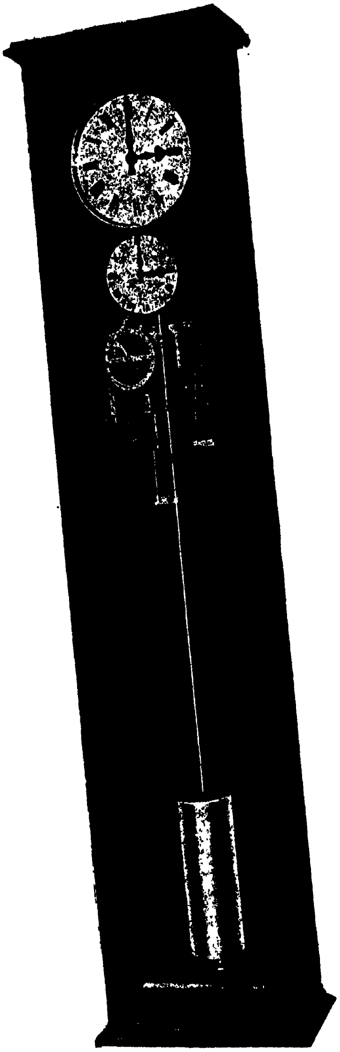

FIG. 8. Slave Clock.

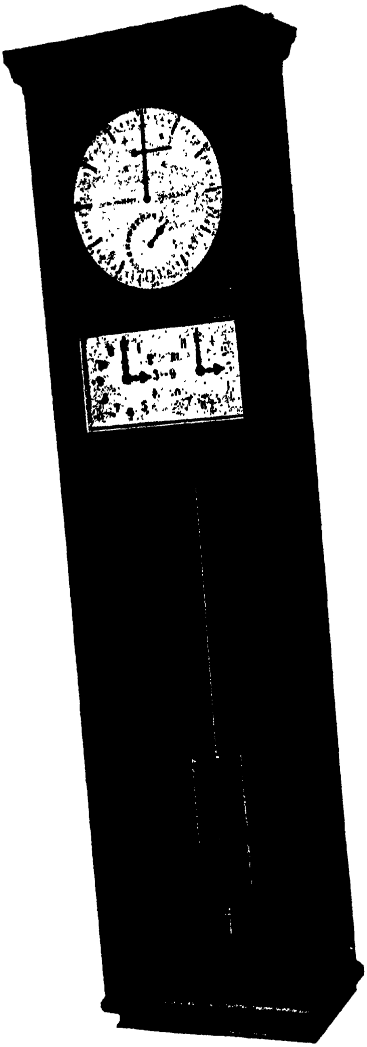

FIG. 9. Slave Clock indicating seconds.

circuits of electrical impulse dials, including turret clocks, just as well as chronograph pen magnets and seismograph recorders, and if the Free Pendulum is a Sidereal, it may control the motion of telescopes used for stellar photography.

It is also a great convenience to be able to set the clock to time. Hitherto it has not been possible to set to time clocks sealed up for constant barometric pressure without breaking the seal. A feature of the Free Pendulum which will be highly appreciated by astronomers is that the slave clock (its only time indicator) can be readily set either forwards or backward, the only limitation is that it cannot be set less than two sceonds either way, that being the period of vibration of the Free Pendulum which, of course, is never touched.

Time has not permitted me to deal adequately with other methods of maintaining and counting the vibrations of a Free Pendulum. I had to choose between an historical and a practical lecture, and I chose the latter, but I must remind you that it can be and has been done by radically different methods, such as by means of a selenium cell, and also by means of the Triode valve. I have, however, found these proposals to be deficient in the counting and switching functions, which are of the utmost importance, and for this and many other reasons I prefer my own methods.

DISCUSSION.

THE CHAIRMAN, in opening the discussion, said Mr. Hope-Jones had given an extremely lucid account of what he himself, at any rate, found rather a difficult subject. One thing about which he felt very strongly was that the author's clock, and the rates which were shown to have been got at Edinburgh, certainly met—and very much more than met—all the requirements of astronomers at the present time. The difficulty of the astronomer was with his instrument; there were questions of stability of his mounting, possibility of flexure in the axis, and so forth, and under those conditions, with such instruments, astronomers did not get anything like as much precision as they did with clocks.

MR. C. O. BARTRUM said that he had recently spent an afternoon at the Edinburgh Observatory, when he had been very much impressed by Mr. Shortt's clock. To see the dream of his youth actually realised before him was quite moving. He had been greatly flattered to find that the humble effort which he had made in 1917, to which the author had made reference in his paper, had been proved by Mr. Shortt's results to have been on the right lines in so very many ways. Unfortunately, his clock had been left in a rough model, and it had never been realised as a properly made instrument. It was rather curious that so many investigators had been working on the same idea without knowing of each other's efforts. For instance, he had never heard of Rudd's clock. When he designed his clock he thought that the slave principle was absolutely new, but he had found that it was quite an old idea. He was pleased to find that Mr. Shortt had dropped his inertia escapement; he had always felt it was wrong. What Mr. Shortt had done was to remove the symptom of a complaint without remedying the disease itself. On one occasion he had ventured to correspond on the subject, and he had to confess that Mr. Shortt had given him a very clever and charming reply which had made him feel rather uneasy.

He considered that Mr. Shortt's clock marked an epoch in time-keeping, and he thought the lecturer had convinced the audience of that fact. Genius was here shown as a combination of simplicity and efficiency, but genius had also been defined as an infinite capacity for taking pains. Mr. Shortt had shown this too by the way he had studied every detail with such care. After all, the carrying out of details and the way in which an idea was developed, was almost as important as the actual idea itself. That was exemplified by the reference which Mr. Hope-Jones had made to the Leroy clock at Edinburgh. Mr. Hope-Jones had described the escapement—a very commonplace idea; it was based on the principle of the old Mudge gravity, but it was so beautifully carried out and made, that the clock was only second to Shortt's, and better than the old Riefler.

He believed it would be agreed that Mr. Shortt's great advances were two in number, firstly, the simple mode in which he synchronised his slave pendulum, and, secondly, the hanging of the master pendulum in a low pressure.

He took exception to what Mr. Hope-Jones had said about inventors not understanding the principle of the slave. Personally he ventured to think he did understand it. When he read his paper before the Physical Society, Professor Boys was in the Chair, and after the paper had been read Professor Boys had made some very interesting remarks, one of which was that his (Mr. Bartrum's) method of synchronising could have been greatly simplified if he had merely arranged that the error of the slave should be wiped out by a definite chunk, either positive or negative. Mr. Shortt had gone one better than that. By keeping his slave with a losing rate he just wiped out a chunk of error and reversed it in one direction only. That was a wonderfully clever idea.

With regard to the low pressure, however, it had been a great surprise to him to find that the resistance to the pendulum had shown such a decrease as the pressure was lowered. He believed the ordinary orthodox physicist would state that the logarithmic decrement of a pendulum, or the dissipation of energy, depended on the viscosity and that the viscosity was independent of pressure. In fact, a learned Professor had given him the figures which Professor Crookes had found as the result of his experiment of swinging a pendulum in different pressures. If the dissipation at atmospheric pressure was taken at 100, when the pressure was reduced to one ten-thousandth of an atmosphere it only fell to 78, and at one-millionth it was still 14. Mr. Shortt had experimented and had found that when he reduced it merely to one-twentieth he had brought down the dissipation of the energy to something like one-fifth. He hoped that Mr. Shortt would publish those results as they would be most interesting. He noticed that the American Geodetic Survey used pendulums hanging in a low pressure—he presumed in order to keep up the swing for a long time.

With regard to the amplitude of vibration, he had discussed that question in his paper with reference to his own arrangement, which was precisely similar to Mr. Shortt's from that point of view, and he had made some experiments. He had come to the conclusion that in a case like this, where the escapement error was likely to be quite small as compared with the circular error, a small amplitude was indicated. He had adopted one degree on each side. Mr. Hope-Jones said that he had taken 140 minutes.

MR. HOPE-JONES: One degree, 40 minutes.

MR. BARTRUM asked if that meant semi-amplitude or the whole.

Mr. Hope-Jones replied the whole.

Mr. Bartrum said therefore that would be 70 minutes on each side.

Mr. Hope-Jones: Fifty.

Mr. Bartrum asked if Mr. Hope-Jones could give any idea of the variation of that amplitude.

Mr. Hope-Jones said it appeared in Professor Sampson's paper of January 14th, read before the Royal Society of Edinburgh. There were some figures given there of the amplitude. Professor Sampson watched the amplitude of the arc very closely under the microscope, but they were small variations.

Mr. Bartrum, continuing, said he desired to conclude by making some general remarks. With his three clocks Dr. Sampson was now getting such records of time that there were indications he was not measuring time, but measuring conditions—either changes of gravity or changes of the earth's magnetic field, or some other changing conditions. Personally he began to think from Mr. Shortt's final result that the next step would be possibly a time-keeper, independent of gravity, and non-magnetic. It seemed to him that they were coming to that—that the pendulum clock had come to finality, because after all, Mr. Shortt measured time to one part in 8-millions. That meant he could detect a change in gravity of one part in 4-millions. He did not know whether there was any possibility of such change, but it seemed to him there were interesting possibilities when one got to such accurate time-keeping.

The Chairman said there was one point he would like to put to the author as a possible limit of the pendulum clock, and that was earth tremors. One got earthquake shocks now and again, and one knew that there were small seismic vibrations. If those should, by any fortunate chance, have a period of two or three seconds, they would, he took it, make an ultimate limit on the accuracy obtainable by pendulum clocks; but there was not the slightest evidence so far. One simply had to say that the evidence was against those seismic vibrations being of such amount as to affect the pendulum.

Mr. Bartrum said that Prof. Sampson had showed him that his three clocks—the Riefler, the Leroy and the Shortt—were at times altering their rate together, as if there was some external effect acting on them all.

Father J. P. Rowland said, with regard to seismic disturbances, he doubted very much if the vibrations, which whilst varying somewhat in magnitude, were always very small, would be likely to affect the clock, but he had often wondered whether small tiltings of the ground, which certainly indicated changes of level with changes of temperature, atmospheric conditions, and perhaps other things, influenced the rate of a clock. It would be extremely interesting if investigations were made as to how far earth movements might limit the accuracy which could be obtained by pendulum clocks. If an instrument were set up to indicate more definitely earth tiltings rather than vibrations, some correlation might be found between the levels and the rate of the clock which would show connection.

Major C. E. Prince said the author had referred to the extraordinary accuracy of astronomical clocks. It was rather interesting to try to discover how much of that accuracy was due to physical perfection and how much was due to perfection of the method. For example, it was obvious that, with a pendulum which was non-expansible and working in a perfect vacuum, any errors would be the errors of the method and not of the pendulum itself. He would have been interested to see the two divisions of the subject separated in order to see how much of the accuracy was due to each of them.

It seemed to be laid down by everybody that the smallest possible interference of the pendulum was desirable, but would it not be more scientifically accurate to impulse as often as possible; that was, to supply energy in far more minute quantities more often? It seemed to him from fundamental considerations that was what ought to be done, but there seemed to be some rule against that which apparently had been arrived at by practice, and which he would like to have explained.

With regard to the question of the accuracy obtained from putting the pendulum in a very low pressure, was that because the pressure was low, or simply because in the containing case the variations of atmospheric pressure from outside were not felt?

Mr. R. J. Low said it appeared from the diagram shown on the wall that the rate was always changing. Had any attempts been made to compare it with magnetic charts over a corresponding period, and also with the gravitational effects of the position of the moon, and the sun, and the tide? Also, were the comparisons taken at exactly the same time every day? He asked this because when he was watching the Synchronome slave clock working, he had noticed that the hit-and-miss governor did not work every time. If one looked into it very carefully one saw that it was undergoing what he might call a rhythmical hunt. It might be the same with the master clock—that if one could analyse its motion carefully enough one would find it was alternately running fast and slow, and that if one got a graph of it it might look something like an ordinary sine curve. When those concerned had compared the clock every day for a week they might have chanced to take all the points above the zero line for one week, and in another week they might have chanced to take them all below the zero line. Had that any bearing on the graph shown on the wall?

With regard to magnetic effects, to his mind it seemed entirely wrong to have a magnetic field anywhere near a swinging pendulum, as this field is never constant, owing to the varying battery voltage and resistance, and also the earth's field. These fields were bound to affect even a metallic pendulum of non-magnetic material, and much more so one of invar, which was magnetic.

The Author, in reply to Mr. Low, said the period at which the clocks were compared every day at Edinburgh was either uniform, or else an allowance was made for any differences which might occur through known causes, and things were brought to a uniform time datum for observation. That was mentioned in the paper to which he had referred, which had been read before the Royal Society of Edinburgh on January 14th last. He hoped it was perfectly clear to Mr. Low's mind that no variation of battery in the electric self-winding action or Synchronome remontoire, could possibly affect time keeping. In many systems of electric clocks he was sorry to say the impulse imparted to the pendulum varied as the battery varied. There was nothing whatever of that kind here. He gathered that Mr. Low objected to the presence of an occasionally active electro magnet anywhere near the pendulum. That was one of those refinements to which possibly people would turn their attention now. Having got down to a fresh datum of accuracy one looked forward to the slightest possibilities. It had never occurred to him before that such things could possibly be a source of variation.

Mr. Bartrum had ably put forward the possibilities of the achievement of such great accuracy in time-keeping leading investigators into deeper considerations altogether—as to whether it was quite Time which they were measuring.

The chart on the wall actually did show the variation of gravity. The question had been asked as to whether the moon was affecting that rate. It had been pointed out to him that for the period of nine months the variations in the chart exactly corresponded with the adding or subtracting of the moon's weight to the earth and gravity. Such matters certainly did want looking into. Some of them might be quite laughable when they came before an astronomer, but the fact that such questions were asked showed the present trend of thought.

Major Prince spoke of the impulse being given more often. He quite admitted that, on the basis of pure reason, it might be very well asked what was the difference between giving 30 very small power impulses, one every second, and one larger impulse equal to those 30 added together every half minute? Theoretically it was the same thing, but in practice it was not. They just had to take it from a common sense point of view and consider which could be done with the least variation. He might say that to divide up that impulse of .43 grammes falling a distance of 2 mm. every half minute into 30, the pivot friction might be 50 per cent. of it every time, and that pivot friction would be subject to variation. He thought Major Prince would see his point. It was just a matter of common sense, what one could do best. Prof. Sampson had expressed to him the opinion that very likely it would be better if the impulse was given every minute instead of every half minute.

A vote of thanks to the author for his paper concluded the meeting.

POPULATION, MIGRATION AND EMIGRATION.

The report of the Oversea Settlement Committee for the year ended 31st December, 1923, refers *inter alia* to a memorandum prepared in the Department of the Registrar General. The memorandum, which is printed as an appendix, deals with the factors governing the growth of population in Great Britain and the tendencies which appear to affect that growth. It shows, says the report, that during the past fifty years the annual natural increase of population in Great Britain, notwithstanding a decline in the birth-rate, averaged, before the war, 418,000, or making allowance for the balance of outward over inward migration, about 361,000 a year. It is suggested that there are no sufficient reasons for anticipating any immediate or considerable departure from this amount of natural increase, but that, while the birth-rate may fall still more, there is less scope for a continued decline in the death-rate.

During the past century the population of Great Britian has increased from 14,681,000, its estimated size in 1823, to over 43,000,000, in 1923. This increase was made possible by the discoveries which created modern industry.

As a result of the disturbances which the war has produced, distress has been widely prevalent in this country, and a large part of the population has suffered from unemployment. This situation has raised the question whether Great Britain is or is not over-populated. This is a problem of extreme complexity. Though closely related with the main subject of this report, viz., migration, it covers a far wider field, and raises many issues upon which the Oversea Settlement Committee are not in a position to express an opinion. They therefore confine themselves to an enumeration of the following factors in the problem, which are directly related to migration, viz.:—

(1) There has been a gradual decline in the birth-rate over the last fifty years, but
(2) the effect of this decline on the annual increment has been offset:—
  (a) by the decline in the death-rate, and
  (b) by the geometrical effect upon numbers of any given rate of increase, but
(3) the great diminution in child mortality, which has been largely responsible for the decline in the general death-rate, cannot be expected to have so marked an influence in the future.

On the other hand, a continuous fall in the birth-rate is impossible to predict, since it may be checked by economic recovery.

(4) Having regard to the foregoing, there is no ground for anticipating a rapid reduction of the annual natural increment of something over 400,000, which has persisted since 1870. (The last two years, mid 1921 to mid 1923, during which the natural increase averaged 372,000, may be regarded as abnormal, owing to the exceptional industrial conditions).

(5) The only other important counterbalancing factor is migration. The average annual deduction to be made on this account for the ten years before the war, as shown by the figures for net outward balance of passenger movement to all countries, was 178,000. (This figure, however, includes Ireland. It was based up to 1912 upon the total passenger movement, and after that date was restricted to persons permanently changing their domicile.) The total net migration for the last two years was :—

1922	106,000
1923	198,000

It is thus apparent that migration has not counter-balanced the net natural increase (*i.e.*, balance of births over deaths) of the population.

(6) In the light of these figures and tendencies, it is at least safe to assert that there is no prospect of migration reducing the numbers of the population of Great Britain in a manner injurious to prosperity.

INDUSTRIAL DEVELOPMENT IN CHINA

In his report on the industrial and economic situation of China, the Commercial Secretary to H. M. Legation, Shanghai, points out that no very striking developments in the form of new industrial enterprises in China occurred during the year under review, progress being naturally hampered by the absence of security which continues to discourage the investment of capital elsewhere than in the main Treaty ports. In certain directions, however, notably in the case of flour mills an match factories, the industry continues to grow,and the native products are competing successfully with the imported article. This is especially the case as regards matches, and the Japanese manufacturers who formerly did the bulk of this business are rapidly being driven out of the market. Another industry which is growing in importance is sugar refining, factories for the manufacture of beet sugar having been established in Manchuria, and another company is at present putting up a large refining plant in Shanghai. The establishment of several new cement factories has taken place during the past three years, one of the largest of these being situated n the neighbourhood of Shanghai and another near Liaoyang in Manchuria. Soapmaking, tanning, knitting factories, canneries, paper mills and carpet factories are other industries in which native companies are engaging in increasing numbers. One may safely say that the industrialization of China on modern lines is proceeding steadily in spite of the obstacles created by the absence of any ordered government in that country, and that if conditions in this respect showed any substantial evidence of improvement the example already set by Shanghai and other ports which enjoy the security afforded by foreign settlements or concessions would soon be followed in every part of the country.

GENERAL NOTE.

Conference on Science and Labour.—The programme of the Conference on Science and Labour to be held at the British Empire Exhibition on May 30th and 31st, has been published. The Conference, which has been arranged by the British Science Guild in co-operation with the National Joint Council of the Trades' Union Congress and the Labour Party, will be opened by the Prime Minister. There will be five sessions, the subjects of discussion being :—(1) The Place of Science in Government; (2) Scientific Research in Relation to Industry; (3) Co-operation of Science and Labour in Production; (4) Science and the Human Factor; (5) Science in Educational Organization. Sir Richard Gregory will preside and Mr. Sidney Webb, President of the Board of Trade, will open the discussion on Science in Government, and Sir Richard Glazebrook and Major Church, M.P., will speak. At the second session Lord Askwith will preside, and the chief speakers will be Mr. Hugo Hirst, Sir Oliver Lodge, Sir Daniel Hall and Mr. A. P. M. Fleming. Mr. C. T. Cramp will preside at the discussion on Science and Production, and the speakers are Lord Ashfield, Sir Hugh Bell and Mr. W. Straker. The fourth meeting will deal with Health and Psychology. Miss Margaret Bondfield, M.P., will preside, and the speakers include Sir Arthur Newsholme, Dr. C. S. Myers, Dr. Cyril Burt and Miss May Smith. At the final session Mr. Arthur Greenwood, M.P., will preside, and the discussion on Science in Educational Organisation will be opened by Mr. R. H. Tawney, who will be followed by Sir Thomas Holland and Dr. R. P. Scott. Copies of the programme and tickets of admission may be obtained by application to the Conference Secretary, 15, Gower Street, W.C. 1.

MEETINGS OF THE SOCIETY.

Ordinary Meeting.

Wednesday :—

May 28 (at 4.30 p.m.)—**Mrs. Arthur McGrath (Rosita Forbes),** "The Position of the Arabs in Art and Literature." **Lord Askwith,** K.C.B., K.C., D.C.L., Chairman of the Council, will preside.

INDIAN SECTION.

MONDAY JUNE 30, at 4.30 o'clock.—J. C. FRENCH, I.C.S. "The Art of the Pāl Empire in Bengal." THE RIGHT HON. THE EARL OF RONALDSHAY, G.C.S.I., G.C.I.E., will preside.

DOMINIONS AND COLONIES SECTION.

TUESDAY, MAY 27, at 4.30 o'clock.—C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "A Sketch of the Geology and Mineral Resources of Cyprus." DR. J. W. EVANS, C.B.E., F.R.S., President of the Geological Society, will preside.

MONDAY, JUNE 2, at 5 o'clock.—THE RT. HON. SIR FREDERICK LUGARD, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member, Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates." THE RT. HON. VISCOUNT MILNER, K.G., G.C.B., G.C.M.G., will preside.

MONDAY, JUNE 16, at 4.30 o'clock.—C. V. CORLESS, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, MAY 26 Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Colonel H. Biddulph, "The True Harmony of Man."

University Extension Lecture, Gresham College, Basinghall Street, E.C., 7.30 p.m. Mr. A. Compton-Rickett, "Personal Forces in Modern Literature: Lecture V.—Walter De La Mare."

University of London, University College, Gower Street, W.C., 5 p.m. Prof. G. D. Hicks, "Kant's Theory of Sublimity and Beauty." (Lecture III.)

At King's College, Strand, W.C., 5.30 p.m. Mr. A. J. Toynbee, "The Saviour King in Greek Tradition."

TUESDAY, MAY 27 Royal Institution, Albemarle Street, W., 5.15 p.m. Major M. S. Tucker, "Acoustical Problems." (Lecture II.)

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 4 p.m. Hon. Sir Joseph Nunan, "India and the Colonisation of British Guiana."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. F. L. Emmanuel, "Etching."

University of London, at King's College, Strand, W.C., 5.30 p.m. Prof. E. Prestage, "The Diplomatic Relations between Portugal and England from 1640 to 1668."

At the Imperial College, Royal School of Mines, South Kensington, S.W., 5.15 p.m. Dr. W. G. Miller, "The Pre-Cambrian, with special reference to that of Ontario." (Lecture III.)

Master Glass-Painters, British Society of, University College, Gower Street, W.C., 3 p.m. (1) Dr. Ethel Mellor, "The Decay of Window Glass from the Point of View of Lichenous Growths." (2) Mr. Nöel Heaton, "The Decay of Mediæval Stained Glass." (3) Prof. W. E. S. Turner, "The Weathering and Decay of Glass."

Royal Dublin Society, Leinster House, Dublin, 4.15 p.m. (1) E. R. G. Atkins, "Notes on the Filtration and other Errors in the Determination of the Hydrogen Ion Concentration of the Soil." (2) J. L. McWhinney, "The Soil Fauna of a Permanent Pasture." (Communicated by Prof. Wilson.)

WEDNESDAY, MAY 28 . Microscopical Society, 20, Hanover Square, W., 7 p.m. (1) Mr. J. E. Barnard, Lecture Demonstration on "Technical Microscopy." 8.15 p.m. (2) Mr. E. Sheldon Leicester, "The Use of the Microscope in the Examination of Paper." (3) Mr. K. MacLennan, "The Microscopy of Soaps."

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. S. Riccobono, "Roman Law and Modern Law." (Lecture I.)

3 p.m. Prof. E. G. Gardner, "Problems of the 'Inferno' of Dante." (Lecture II.)

At the Lodon School of Economics, Clare Market, W.C., 5.30 p.m. Prof. A. J. Sargent, "The Trade of the Empire."

THURSDAY, MAY 29 Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8.30 p.m. (Wilbur Wright Memorial Lecture.) Colonel H. T. Tizard, "Fuel Economy in Flight."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m. (Croonian Lecture). Prof. D. M. S. Watson, "The Structure, Evolution and Origin of the Amphibia.

Antiquaries' Society, Burlington House, Piccadilly, W., 8.30 p.m.

Royal Institution, Albemarle Street, W., 5.15 p.m. Prof. C. G. Seligman, "Divine Kings and Rainmakers of the Sudan."

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. S. Riccobono, "Roman Law and Modern Law." (Lecture II.)

5.30 p.m. Prof. R. W. Chambers, "Ruskin on Byron."

At King's College, Strand, W.C., 5.30 p.m. Prof. A. J. Toynbee, "Outlines of Byzantine, Near Eastern and Modern Greek History (378—1841 A.D.)." (Lecture VI.)

Transport, Institute of, Grand Hotel, Bristol, 10 a.m. Annual Congress. (1) Mr. D. Ross-Johnson, "The Port of Bristol, Past and Present." (2) Colonel E. S. Sinnott, "The Problem of Road Surfaces with regard to Mechanical Transport."

FRIDAY, MAY 30 Mechanical Engineers, Institution of, (South Wales Section), University College, Swansea. Summer Meeting.

Geologists' Association, University College, Gower Street, W.C., 7.30 p.m.

Sanitary Institute, Royal Spa Rooms, Harrogate, 4.15 p.m. Discussion on "Public Health Services: Are they worth the money expended?"

Royal Institution, Albemarle Street, W., 9 p.m. M. Lucien Bull, "Recent Developments in High Speed Cinematography."

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. H. Pirenne, "Les Périodes de liberté et de réglementation dans l'histoire économique." (Lecture I.)

5.30 p.m. Miss Marjory S. West, "The Old Testament." (Lecture III.)

Shakespeare Association, King's College, Strand, W.C., 5.30 p.m. Mr. C. Rhodes, "The Acting of Shakespeare in the Provinces."

Transport, Institute of, Grand Hotel, Bristol, 10 a.m. Congress continued. (1) Mr. H. R. Griffiths. "Freight Train Formations." (2) Colonel W. A. Bristow, "The Next Five Years of Aerial Transport."

SATURDAY, MAY 31 .. Royal Institution, Albemarle Street, W., 3 p.m. Mr. C. Nabokoff, "Shakespeare in Russia."

Journal of the Royal Society of Arts.

No. 3,732. VOL. LXXII.

FRIDAY, MAY 30, 1924.

All communications for the Society should be addressed to the Secretary, John S[illegible] Adelphi, W.C.2.

24. JUN. 1924

NOTICES.

NEXT WEEK.

MONDAY, JUNE 2nd, at 5 p.m. (Dominions and Colonies Section.) THE RT. HON. SIR FREDERICK LUGARD, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member, Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates." THE RT. HON. VISCOUNT MILNER, K.G., G.C.B., G.C.M.G., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

SOCIETY'S ALBERT MEDAL.

The Albert Medal of the Society for the current year has been awarded by the Council, with the approval of HIS ROYAL HIGHNESS THE PRESIDENT, to HIS ROYAL HIGHNESS EDWARD, PRINCE OF WALES, K. G., "in recognition of services rendered to Arts, Manufactures and Commerce as President of the British Empire Exhibition, and by his visits to the Dominions and India."

TWENTY-SECOND ORDINARY MEETING.

WEDNESDAY, MAY 21st, 1924; SIR HERBERT JACKSON, K.B.E., F.R.S., in the Chair.

The following candidates were proposed for election as Fellows of the Society :—

Allen, John Scott, Lismore, Ireland.
Blake, Captain Sir H. Acton, K.C.M.G., K.C.V.O., London.
Cawston, Frederick Gordon, M.D., B.Ch., M.R.C.S., L.R.C.P., Durban, South Africa.
Daniell, Major John Alan Le Norreys, Sudbury, Suffolk.
Longman, Charles James, M.A., J.P., London.
Mattocks, Captain, F.S., R.E., Quetta, India.
Rummell, G. Albert, Cincinnati, Ohio, U.S.A.

The following candidates were duly elected Fellows of the Society :—

Airth, George Rennie, London.
Broemel, Percy Rudolph, London.
Graham, Edward Alfred, Beckenham, Kent.
Webber, Henry O'Kelly, Johannesburg, South Africa.
Wreford, Ernest Henry, East St. Kilda, Australia.

The seventh Trueman Wood Lecture on "The Outlook in Chemistry" was delivered by SIR WILLIAM J. POPE, K.B.E., D.Sc., LL.D., F.R.S., Professor of Chemistry in the University of Cambridge.

The lecture will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

WEDNESDAY, 30TH APRIL, 1924.

MR. HARRY GOSLING, C.H., M.P. (Minister of Transport), in the Chair.

THE CHAIRMAN, in introducing the lecturer, said that one thing had struck him, namely, that, whenever there was a discussion about road improvements, it was surprising the number of people who came to him in the position which he was at present enjoying and said "Now, whatever you do, be careful not to destroy anything which is old and beautiful, and be sure you do not attempt, in making your improvements, to interfere with those things which have been regarded for centuries as almost sacred." On the other hand, there had to be taken into consideration the question of the losses to trade and commerce through the absence of facilities for traffic. Being one of those who believed that there could not be good business unless there was good transport, he felt he had now connected himself with one of the most serious problems of the day. He was happy in the thought, however, that he would not be troubled with the question of interference with any beautiful structures in the area with which Sir Henry was going to deal that night! He remembered that not very long ago a new dock had been opened in that neighbourhood, and some very distinguished visitors were going down there to perform the opening ceremony. The authorities had had to consider how to get them there; there was not a road fit to take them down, and eventually, in order to avoid drawing the attention of those distinguished visitors to the poverty of that neighbourhood in good means of road transit, they had had to be carried on the old highway—the river.

Then there was the difficulty of finance. Another set of people came along and said "What about the money? Who is going to pay for it." He had been driven to the conclusion—and he asked his hearers not to think it was Socialism—that our great main roads would have to be regarded from a national standpoint, more particularly when he remembered how many of the local authorities, in whose districts better transit facilities were needed, could not find the necessary money to do the work. In that connection he was not speaking merely of London but of great agricultural districts. Therefore, much as he was opposed to some forms of Socialism, he believed that one of the great social reforms in this country was the improvement of main roads, and he thought all would have to put their hands in their pockets equally to find the necessary money. It was not only the district in question, but the whole of London which would benefit if improvements such as Sir Henry was going to elaborate that night could be brought about. Anybody who had been connected with a great port must know that a port was not complete until suitable avenues had been made which conveyed goods to and from the port. He was hoping that some business body would try to find out what was lost by not having such roads. He had often wondered himself how much bad roads cost the country in the way of money, to say nothing of the delay.

It used to be said at one time that all roads led to London. Personally he would say that all roads led from Maybury. Sir Henry was an enthusiast and an authority on the subject, and he would now ask him to tell the audience everything about the proposed new road.

The paper read was :—

THE VICTORIA DOCK DISTRICT AND ITS ROADS.

By Sir Henry Maybury, K.C.M.G., C.B., M.Inst.C.E., Director of Roads, Ministry of Transport.

Among Londoners it is customary to speak with bated breath of the "Square Mile," signifying thereby, of course, the City of London—that Thames-side hillock which is so densely clad with buildings that we are apt to lose sight of the river which forms the real foundation of London's wealth—the river Thames with its docks, wharves and grimy foreshore.

Let me, therefore, take you to-night to another riverside "square mile" which is not the City, but which is fundamentally almost equally important—I mean the dock district lying immediately east of the River Lea and known for the greater part as Silvertown.

End to end along the north edge of this district lie the Victoria Dock and the Royal Albert Dock. Immediately south of the latter is the King George V. Dock, capable of taking vessels of the Olympic Class, while north of the Albert Dock lies a site for a still larger dock.

You will see that we have here the most imposing cluster of docks that London can shew, while the Thames frontage of Silvertown is occupied almost exclusively by large works and factories, all giving rise to busy traffic, heavy both in volume and weight. Add to this the flow of vehicles to and from the Woolwich Ferry—that invaluable link between Essex and Kent—and you will appreciate the importance of road-communications in this area. Nor has the climax yet been reached, for the new dock to which I have alluded has not yet been begun, and land still remains vacant for future industrial development.

By one of the humorous anomalies of metropolitan government Silvertown forms no part of the administrative County of London, but is included in the County Borough of West Ham, which has suffered from the malady of unchecked distension. Its population in 1861 was 38,331 and in 1921 eight times greater—300,860. West Ham has never possessed the resources or influence effectively to control the development of Silvertown, much less the amazing contortions of the River Lea which impose such difficulties on bridge-builders.

The neighbourhood is one of those which, as Dickens complained in 1854, "the legislature leaves to come into existence, just as it may happen; overthrowing the trees, blotting out the face of the country, huddling together labyrinths of odious little streets of vilely constructed houses; heaping ugliness upon ugliness, inconvenience upon inconvenience, dirt upon dirt, and contagion upon contagion."

The result at Silvertown provides town-planners with conspicuous examples of what to avoid. For our ancestors' want of foresight the penalty has long been accumulating, and payment is now overdue. It is my task to-night to deal with one phase only of the arrears—road communications

—to show you what disabilities the district now labours under, and what means of relief might be applied if London as a whole would put its shoulder to the wheel, as I am fully convinced it will do.

Before dealing with the present plight of this area, it will be interesting to cast a glance backwards and observe some of the stages through which its development has passed, in days when its future industrial importance was little suspected.

From the earliest times until shortly after 1800, the crossing of the River Lea at Canning Town was by a ferry connecting with a rough track leading to Barking, whence a narrow circuitous road skirted the northern edge of the marshes to Tilbury. Across these marshes ran a few cattle tracks, some of which led down into the riverside flats which have since become the Silvertown and North Woolwich Dock areas. The whole tract of country crossed by the Barking Road was so low-lying and unhealthy as to support few living beings save the sheep, horses and cattle which grazed there. The depressing dampness and fogs seem to have reacted on the health and characters of the scanty human residents, for in 1700 one of the historians of the time, records that the people had a peculiar character derived from their unwholesome environment. He stigmatized them as "persons of so abject and sordid a temper that they seem almost to have undergone Nebuchadnezzar's fate, and by conversing continually with the beasts to have learned their manners."

These marsh lands were the happy hunting ground of horse thieves and have a legendary association with Dick Turpin, who used the Hackney Marshes, a little farther north, as his headquarters and refuge, being conveniently close to the roads through Epping Forest.

Extensive schemes for dyking and draining these Thames-side flats were undertaken at the end of the 16th century, the work being usually left to Dutch immigrants, who were acknowledged experts in the science of land-reclamation.

To the English of that day the introduction of foreign labour was as unpalatable as the innovation of systematically draining and dyking the marshes. Popular feeling was expressed in a ballad of the time from which the following is an extract:—

"Our smaller rivers are now dryland
Our eels are turned to serpents there,
And if old Father Thames play not the man
Then farewell to all good English beer.
Why should we stay then and perish with thirst,
To the New World in the Moon then away let us go,
For if the Dutch Colony get thither first,
'Tis a thousand to one that they'll drain that too."

A slide has been prepared shewing the area as it was in 1807 when the district was roused from its sleep of many centuries duration by the commencement of the Barking Road—the East India Dock Company having decided to build a new highway to facilitate the transport of goods from Essex to the Company's docks, and also to provide a shorter route to the metropolis from Barking, where fish intended for London was landed.

A cast-iron toll-bridge across the Lea was built and opened in 1810—the total width of the bridge between parapets being only 28 feet. There were four narrow side-spans and a wider central opening for river traffic.

The road did not at first realize the promoters' expectations; being built for the most part on marshy ground it became so spongy that heavy traffic avoided it. Some 15 or 20 years elapsed before it became thoroughly serviceable.

Several years passed before the man at the toll bridge took enough money to pay his own wages; frequently owing to the poverty of the inhabitants he had to accept a pocket knife or some similar article in default of the regulation half-penny which the wayfarer was unable to produce.

This original iron bridge was designed by Mr. James Walker, then president of the Institution of Civil Engineers. It was composed of cast iron semi-circular ribbed arches with supporting columns of the same material. Later on the original approaches, which were very steep, were modified and easier gradients formed. The toll was abolished, I believe, in 1871.

In 1811 a horse ferry across the Thames was established between Old Charlton on the South and the spot which was to become North Woolwich. Advantage was thus taken of the new Barking Road and a useful means of transit provided for Kent farmers taking their cattle to the Romford market. A road connecting the ferry with the Barking Road was built following existing tracks across the marshes. It is still called Prince Regent's Lane, and was widened about 20 years ago to its present width.

The Manor Road, which you see to the right of Prince Regent's Lane, and also connected with a ferry to the Kentish Shore, is a very much older road and appears on maps as early as 1720. No doubt it existed long before that date.

The Barking coach ran twice daily from the Bull Inn, Barking, to the Bank, the return fare being 3/- inside and 2/- outside. Seats were booked overnight. The guard used to blow his horn when on the Iron Bridge at 12 o'clock noon, and so announce the hour to the scattered houses round. As late as 1845 there were only 6 houses between Plaistow and the Iron Bridge. It was at about this time that the Ripple Road from Rippleside to Dagenham was constructed to give better communication with Tilbury.

In 1847 a railway was built to the ferry in North Woolwich, and the promoters also formed a syndicate to buy the land lying between the Barking Road and the Thames. Houses were built in North Woolwich, but owing to the unhealthiness of the marshes and despite cheap season tickets, the venture was a doubtful success. To encourage the population a garden was laid out there, for bowling, dancing and other distractions. These grounds were acquired by the public in 1890, and are now administered by the London County Council as the "Royal Victoria Gardens." At about the middle of the 19th century, there also came into existence the line of road from Canning Town to North Woolwich, which passes by the White Gates, and is now known as the Dock and North Woolwich Road.

The most important stage in the growth of this neighbourhood occurred in the latter half of the 19th century; the advent of steam and of larger iron ships called for more spacious dock accommodation, and in 1855 the Victoria Dock Company opened the Victoria Dock, which was immediately an enormous success, and in 1860 attracted 854,000 tons of shipping.

About this time the loop road, which passes Connaught Road Station, was built, and this concludes the record of any important highway development in the district, although the area of the docks has since been more than doubled, and the tonnage of shipping has risen in the phenomenal degree indicated in the subjoined table, for which I am indebted to the Port of London Authority:—

Net Register Tonnage of Loaded vessels from Foreign and Colonial Ports entering the Royal Victoria & Albert and King George V. Docks to discharge.

Year.	Net Register Tonnage.
1865	327,643
1866	330,286
1867	361,527
1891	1,497,551
1892	1,536,551
1893	1,639,175
1921	2,426,918
1922	3,078,770
1923	4,148,443

N.B.—The Royal Victoria Dock was opened in November, 1855, the Royal Albert Dock in July, 1880, the King George V. Dock in July, 1921.

In 1880 the London and St. Katherine Dock Company, which had absorbed the Victoria Dock Company, opened the Royal Albert Dock. At that time the largest vessel coming regularly to the Port of London was the Queen, of the National Line, with a tonnage of 4,457.

In 1870 the Beckton Road was built by the Gas Light and Coke Company, and the Southern portion still remains their private road.

In 1887 a steam tug colliding with the Iron Bridge across the Lea, made it unsafe, and eventually the London County Council decided to build a new structure, which was opened in 1897—and is still in use. It has a total width between parapets of 55′ 0″, and was designed by Sir Alexander Binnie. It is composed of 12 mild steel ribs, having a span of 150′. The approaches to this bridge are a constant source of delay, especially to horse-drawn traffic, for in addition to the difficulty of the 1 in 29 gradient on the Eastern approach, there is a sharp curve to be negotiated, paved with granite setts on which horses are constantly in trouble. So frequent is the interruption to traffic from this cause that special appliances are held in readiness to assist horses out of their difficulties.

This bridge carries the major portion of the traffic between London and the Victoria, Albert and King George V. Docks as well as the numerous factories in the Silvertown, Canning Town, East Ham and Barking districts, and a considerable portion of the road traffic to the Tilbury Docks; it also bears agricultural and market garden traffic between South Essex and London.

To bring our history up to date, there remain to be recorded the birth of new industries, the concurrent growth of population and traffic, the opening of the King George V. Dock in 1921—in fine a stir of activity in every sphere except that of civic design and roadmaking, which have always been the two crying needs of Silvertown. One saving clause may be inserted; in 1921, the Ministry of Transport undertook, with the aid of various local authorities, the construction of the East Ham and Barking Bye-Pass which, when completed, will provide a new eastern outlet to this dock district, and will afford spacious means of access to a wide stretch of Thames-side land yet to be developed, and, let us hope, developed with due regard to the painful lessons of the past.

I refer with some pleasure to this new arterial road, since it forms the first chapter in what I trust will be a comprehensive volume of riverside improvement.

The foregoing recital will serve to shew you how an all-important dock district has grown up without any care or foresight being bestowed upon the vital factor of road access—whether for goods entering and leaving the docks or for the army of workers engaged in handling them.

However, for good or evil, there is the legacy that London inherits. Let us look the gift-horse in the mouth and examine the principal blemishes.

First and foremost, approaching from the London end is the "Iron Bridge," which I have already described. It is the funnel through which are poured all the streams of traffic bound for riverside and dock destinations from Poplar to Tilbury—sixteen miles as the crow flies, and including about 20 miles of river frontage, rich in potentialities. This Iron Bridge of which I have mentioned the limitations and inconvenience, was the subject of a traffic census taken in December, 1922, when it was found that the roadway was carrying 32,103 tons of traffic in 24 hours, exclusive of pedestrians.

Mechanically propelled vehicles represented 80 per cent. of this total—a somewhat low proportion, showing what a considerable part is still played in the dock district by horse-drawn vehicles.

Judging by a previous census taken 9 years earlier, the increase of traffic in that period may be computed at about 18 per cent.

Proceeding eastwards from the Iron Bridge, we encounter at a distance of 200 yards two obstructive features which continually impede the flow of traffic, viz., first the bridge over the railway at Canning Town where a girder projects up into the centre of the roadway, and secondly the right-angled junction of the Victoria Dock Road, the traffic from which surges into the Barking Road, at this already congested and obstructed point on a rather trying up-grade. Confusion and delay are consequently unending.

We now turn south down the Victoria Dock Road, which has a carriageway only 21 feet wide where it joins the Barking Road, and where heavy traffic has to swing out widely in order to clear the right-angled corner. This narrow width of 21 feet is maintained for a distance of nearly half-a-mile, when we arrive at the sadly notorious level crossing known as the White Gates, a most prolific source of delay—since the entire rail traffic to and from this dock area passes between these gates. On the adjoining roads the line of waiting vehicles often extends over 300 yards towards Canning Town; as many as 130 vehicles have been counted in this queue.

The following figures supplied by the Borough Engineer of West Ham are very informative, both as to volume of traffic and the hindrance to which it is subject. They do not by any means shew the total road traffic to and from the docks, for much of the traffic takes the Northern loop road towards the Connaught Road Station, and so avoids both the White Gates Level Crossing and the further delay at the swing bridge across the entrance to the Victoria Dock, of which more anon.

In 1904 the average number of vehicles passing the White Gates in 24 hours was 2,173, in 1913 it was 2,496, and in 1922 it was 2,852.

The gates had to be closed for the passage of trains for an average, in

1904 of 10 hours, 36 minutes, in 24 hours;
in 1913, of 9 hours 39 minutes;
and in 1922, of 9 hours 6 minutes.

It will thus be seen that the road is completely blocked to traffic for an average of 40 per cent. of the 24 hours, but at the busiest periods of the day the gates are closed for 47 minutes in the hour.

Just short of the White Gates level crossing the Victoria Dock Road divides: one branch becomes the Dock and North

Woolwich Roads leading southwards, while the other branch (Victoria Dock and Connaught Roads) skirts the northern side of the docks; both branches eventually re-unite in the Albert Road leading to the ferry. All these roads have a carriageway which varies in width from 20 feet to 26 feet—rarely more—and generally speaking only one footway will be found, about 7 feet wide.

The chief and by far the most notable inconvenience to traffic is caused by the level crossings and swing bridges which are a conspicuous feature of both branch roads. On the Northern branch in the vicinity of Connaught Road Station, immediately following a right-angled bend in the road, are in close succession (1) a level crossing over the Beckton Branch Railway, (2) the level crossing over Gallions Branch Railway; (3) the level crossing over the goods railway serving the northern side of the docks (each crossing having its own set of gates), (4) the swing bridge over the passage connecting the Victoria and Albert Docks, and (5) the level crossing over the goods railway serving the Southern side of the Albert and the Northern side of the King George V. Docks. Each of these obstructions may in turn hold up a vehicle wishing to pass, and delays of as much as ¾ of an hour are fairly common at the busiest times of the day. When the north-bound traffic seeks to make its way past the accumulated south-bound vehicles the confusion and congestion are almost indescribable, particularly at the corners, and opposite the large cold storage and other warehouses.

On the southern branch the obstructions are equally severe. However keen competition may be elsewhere, no buses venture down these routes.

A short distance after passing that formidable barrier, the White Gates, which I have already described, you reach the swing bridge across the lock entrance connecting the west end of the Victoria Dock with the Thames. This is a single track bridge and its 9ft. carriageway also forms the track of the goods railway serving the south side of the Victoria Dock. While railway trucks are passing, which they do many times a day, vehicular traffic is necessarily obstructed—and as many as 164 vehicles have been counted waiting to pass this bridge. There is another obstructive level crossing near Silvertown Station.

The effect of these adverse conditions at the Iron Bridge, the Canning Town Railway Bridge, the junction with the Victoria Dock Road, the swing bridges, the White Gates and the other level crossings, becomes cumulative, since all these obstructions are so close together that when one is removed the flood of dammed-up traffic is immediately added to the block already forming against the next barrier. The delays attendant upon the level crossings and swing bridges not only affect vehicular traffic, but they are a constant source of bad time-keeping by factory employees, and the inadequate road connections and approaches militate seriously against further commercial enterprise in the district.

So large a proportion of London's vehicular traffic originates or terminates at the Docks that we may say without exaggeration that delays here produce a retardation of movement throughout the entire Metropolitan area—a fact which strengthens my plea for contributions towards the cost of the improvement from the widest possible region.

Through the courtesy of a well-known haulage contractor, I have recently had an accurate log kept for several entire days on certain lorries performing their usual journeys in and around the Silvertown area—the longest individual journey being approximately 4½ miles. Tabulating these records, the deduction can be made that approximately 35 per cent. of the time occupied by the journeys is absorbed in the delays caused directly and indirectly by the obstructions I have enumerated, such as swing bridges, level crossings, etc.

So much for the growth of Silvertown and the woeful tangle in which it now finds itself.

I pass to the pleasanter subject of possible remedies, though it is well to remark at the outset that no cheap cure can be prescribed. High though its cost may be, however, I am satisfied that the vital interests of the Imperial Capital demand the immediate inception of this scheme, the urgency of which was recognised as far back as 1912, when the Road Board (since absorbed in the Ministry of Transport) offered to contribute £100,000 towards the outlay involved. I fear by the way, that £100,000, which sounded a large sum in the frugal days of 1912, will not go far towards the cost of the scheme which I am about to describe, and which will be illustrated by lantern slides photographed

from maps and a model prepared for the purpose of simplifying the study of the problem.

We will start in the East India Dock Road, on the London side of the River Lea. This road, as the result of recent widenings measures now 50 feet in width, between the kerbs, but narrows down, unfortunately, at the corner of Leamouth Road, where the curved approach to the iron bridge begins. Let us begin by widening the East India Dock Road from Leamouth Road eastwards to a dimension of 100 feet, remove the old tortuous iron bridge and build a new structure 100 feet wide in nearly direct alignment with the Barking Road on the other side of the Lea. We ought then to widen the Barking Road to the same dimension of 100 feet up to the point where it will intersect with a remodelled and re-aligned Beckton Road. This improvement of the Barking Road will obviously be a costly matter, involving demolition of property down one side at least, the re-building of Canning Town Station and the widening of the railway bridge there.

Beckton Road, which as I have just said, will need to be re-modelled and re-aligned, will possess great importance in the near future, as forming the western extension of the East Ham and Barking By-Pass now nearing completion. Although termed a by-pass, it will be in fact the direct London-Tilbury Road, and enable drivers to avoid East Ham, Barking and other congested areas.

It will therefore be necessary to widen Beckton Road to the same dimension as the East Ham By-Pass, namely, 100 feet, and to straighten out its western end so as to give it a direct discharge into the Barking Road, instead of bending unnecessarily northwards as it does now.

The works just described in connection with the East India Dock Road, the Iron Bridge, the Barking Road and the Beckton Road, will afford a clear channel for traffic from London eastwards, and it now remains for me to explain what can be done to enable traffic to penetrate southwards through the tangle of level crossings and swing bridges, so as to reach Silvertown and destinations in the dock district generally.

To follow this part of the scheme we must return to the new eastern approach of the Iron Bridge. You will remember that the narrow Victoria Dock Road here joins the Barking Road at right angles. Instead of adopting this line, let us build a boldly curved road 80ft. wide, springing from a point somewhat further west. Instead of dipping down to the present street level, we will follow an ascending course and place our new road on a viaduct set some 200ft. east of the present Victoria Dock Road.

The existing maze of cross roads will pass underneath the viaduct, as will also the railway lines which now inflict such incalculable delays upon road traffic at the White Gates. Our new viaduct will also pass at a high level over the western outlet from the Victoria Docks, where, instead of the present single track bridge, a new swing bridge 60ft. wide would be provided for vehicles and pedestrians. From this point southwards the new viaduct would descend by an easy gradient to join the existing North Woolwich Road, near the intersection of Cranbrook Road.

At one point on our new viaduct a spur road will have to be constructed to enable traffic from the Tidal Basin Road to ascend to the higher level of the viaduct.

Those employers and workers whose daily routine brings them into perpetual, irritating contact with the present traffic obstructions, will best appreciate what invaluable relief would be afforded by the creation of this high level road which would, in my judgment, amply justify the cost of its construction and the incidental disturbance of trade and property.

Obviously, that disturbance, although temporary in its nature, will be fairly extensive. Measuring the length of the portions of the East India Dock Road and the Barking Road which have to be transformed (including the new bridge), we reach a dimension of 1,000 yards. The widening and extension of the Beckton Road accounts for another 1,600 yards, while the new viaduct road measures about 2,000 yards in length, including the swing bridge.

The widening of streets and the clearance of property required for the new roads will entail the demolition of nearly 700 houses, but few of these buildings are of such a character as to call for an apology for their removal. Indeed, I suspect that housing reformers will welcome the ventilation of this congested area by the piercing of a new road. In any event, there is no making of omelettes without the breaking of eggs, and in this case we have the consolation that the substituted accommodation built for displaced residents will certainly show great advantages over the present tenements. I should hope that the re-housing might be carried out, with the concurrence of the London County Council, on the large Estate which they are now developing on the most advanced modern lines at Dagenham, 4½ miles from Silvertown. The East Ham By-Pass when completed in a year's time, will afford rapid and direct communication between Silvertown and this new Estate.

Apart from tenements and dwellings which will be destroyed, certain great undertakings, such as railways, riverside interests, etc., will be affected by the scheme (I have mentioned, for instance, the alteration of Canning Town Station).

Taking a long view, however, I am confident that in the outcome, nothing but benefit can accrue to all concerned, seeing what a handicap is now imposed on every local enterprise by the congestion of road transport. Certainly nothing is to be gained by postponing the improvement. If we wait until impending dock developments are put in hand, it is difficult to see how road works on a large scale can be initiated without causing intolerable inconvenience. In the most favourable circumstances, a scheme of the magnitude I have sketched, costing two or three million pounds, would require four or five years for its execution, and prudence would suggest that the re-housing should be begun well in advance of the rest of the project.

Allow me to say that I claim no originality in the authorship of the proposals I have laid before you this evening. It has merely been my aim to focus attention on what I believe to be one of the most urgent improvements conceivable, and one that I am proud to have the privilege of advocating.

If anyone is inclined to think that the proposals err on the side of extravagance, I would ask him to glance at two slides which show the stately magnificence of the road communications at the foreign ports of Marseilles and Havre.

May I be allowed to close this paper with an earnest appeal to London as a whole, London in its widest sense, to combine its incalculable resources for the launching of the great improvement scheme which I have described to you? Such a scheme has been advocated and debated for twenty years or more.

It can neither be treated as a local scheme to be undertaken by West Ham, nor as a national scheme to be financed solely by the government. The local factor and the national factor are not to be overlooked, but, rightly considered, the project is first and foremost an All-London task, the cost of which should be distributed over a wider region than the Metropolitan Police Area. So great a campaign demands united forces led by a spirit of vision and venture. The Home Counties which derive so much of their wealth and rateable value from their vicinity to London, should not stand aloof.

Again, what body could be more closely concerned in the improvement of traffic facilities to the Docks than the Port of London Authority? My experience of the willing collaboration of the London County Council and other metropolitan authorities in the construction of new arterial roads gives me confidence that they will not be found wanting on this occasion.

A host of other possible contributors come to my mind, but I refrain from mentioning them by name, as I should be loth to rob them of the credit of making the first advance, in the course of the discussion to which I am now eagerly looking forward.

DISCUSSION.

Sir Joseph Broodbank, in opening the discussion, said Sir Henry Maybury had treated the subject so exhaustively that there was little left for him to say, except to support most heartily the project which had been advocated that evening. Sir Henry Maybury had achieved many mighty works, for which his contemporaries were grateful, and for which posterity would be thankful. Sir Henry was one of those men who, to quote George Eliot, had the practical sense which seized upon opportunity and the energy which arrived in time. He was also one of those men who, once having taken up a subject, persisted in it, and would not drop it until something had been achieved. The present matter had not been taken up by the Ministry of Transport any too soon. Personally he knew most of the ports of Europe and of this country, and he could not call to mind any which had such bad road approaches as the London docks. The same could not be said of the railway, or of the river access, but the roads were very bad. Until the Ministry of Transport had taken up the subject seriously there had not been a single road, except one which he would mention later on, which was equal to what the Port of London, being the chief port of the world, was entitled to have.

One of the approaches to the Port of London had not been touched upon, but to his mind, it was as bad as any, namely, the Whitechapel High Street, with what was known as Gardeners Corner, which throttled the whole of the dock traffic going from east to west.

The Chairman had referred to the part which the State might take in the making of great routes through this country. It was interesting, with regard to the London dock roads, to note that when the West India Dock and the East India Dock had been made there had been no road access to Poplar except the very narrow road which ran along the riverside. The West India Dock Company and the East India Dock Company had constructed a road themselves. The present Commercial Road with its spurs, the East India Dock Road and the West India Dock Road, had been constructed by the West India Dock Company and East India Dock Company, and had been worked as toll roads for many years. He thought, for a private venture, the successors of the directors of that day could be proud of those works. If it had been worth the while of those Companies to construct roads to their docks, surely it was worth the while of those concerned in the lower docks also to assist in making their roads. It was quite true that in 1855, when the Victoria Dock had been opened, nothing had been done in that way, but there was a reason for that. The Victoria Dock Company had depended on railway access and on water access; they never contemplated the developments in cartage, and in its early days cartage had been so expensive to the Victoria Dock, before the days of motors, that most of the traffic went by rail and not by road. That accounted for the fact that the accesses were so inferior at the present time to the lower docks. He heartily supported the general lines of the author's proposal. He had seen half a dozen schemes to overcome the trouble, but Sir Henry Maybury's commended itself to him as the cheapest. The only doubt he had with regard to it was whether it was necessary at any rate for the branch road to be so wide as 80 feet. It had to be remembered that the land on the South of the Victoria Dock and the Albert Dock was practically fully occupied by factories; there was not really much room for development. It had also to be borne in mind that the immediate future developments of docks in London were just as likely to take the form of an enlargement or development of the West India Dock area, the Millwall Dock area (which was far from developed) and the Surrey Dock, which was also in an undeveloped state. He would also like the audience to remember that the chief channel of the traffic which went in and out of the docks was carried by lighter, and not by cart or rail. That fact could not be ignored. The difference between a 60 ft. road and the present wretched thoroughfare was immense, and the expense could not be ignored. He saw that a figure of between £2,000,000 and £3,000,000 had been quoted. If such a scheme as the author had foreshadowed was going to be carried out, he did not think it would be found that £2,000,000 or £3,000,000 would cover the total cost. Independently, however, of such details he backed the scheme for all he was worth.

Sir Lynden Macassey, K.B.E., desired to express what he believed was the predominant feeling of every person who had listened to Sir Henry Maybury, namely, their deepest appreciation for the exceedingly able and masterly way in which he had dealt with an extraordinarily difficult subject. He remembered very well that when he had been Secretary to the Royal Commission, a proposal, not on the same lines exactly, but fulfilling the same purposes, had been pressed very strongly upon that Commission's attention by the inhabitants of the Silvertown district. Those people had put forward the view, which he thought every reasonable person must accept as the fair view, that they could not as a local Authority be called upon to foot the bill for an improvement so essentially necessary for the Port of London, and so vital for the interests of those who lived in the Metropolis; but there had to be borne in mind the fact that when, in the early days of the last century, three or four Royal Commissions urged that improvements of such a sort in the London area ought to be made a national cost, that proposal, which he could not help thinking was the right proposal, had been defeated by the Local Authorities, who, short-sightedly, insisted that each parish, on the principles of Bumbledon, should have the sole right to construct and look after their own roads. Over a hundred years ago the principle which Sir Henry had urged had been laid down by four Royal Commissions, namely, that these great improvements, which affected so materially the life and the economic welfare of the Metropolis, ought to be dealt with not upon parochial grounds but on national grounds. The ports of Marseilles and Havre entirely owed their road access to the far-sightedness of Napoleon. Unfortunately, we in this country had not a Napoleon (we might have one at the moment) in charge of the transport of this country, but there was great scope for adopting the same drastic measures as Napoleon had adopted.

He had had some time ago to go carefully into the evolution of the roads in the neighbourhood of London. The reason why the particular district with which Sir Henry Maybury had dealt, at the beginning of the last century, had been devoid of roads, dated back to Roman times. At the time of Cæsar's invasion the trade route from London to the Kentish ports went up to Lambeth, crossed the river from Lambeth to Westminster, and then went on to St. Albans, which was then the capital. When the capital had been changed to Colchester, the trade route diverged up to Southwark, crossed the river from Southwark to London, then went along the main road to Ilford right out to Colchester. From that time until Tudor days, and from Tudor days, with little modifications, to certainly the late Stewart days, the old maps showed absolutely nothing in the way of road improvements in the particular district dealt with by the paper. The reason was, of course, that every parish was looking after its roads in a way in which every parish might be expected to look after its roads, and he personally saw no hope whatever of overcoming the very great transit difficulties which existed in such a district as Sir Henry Maybury had dealt with unless the matter was taken up by the Government, and unless not merely peaceful persuasion, but something in the nature of more direct action was adopted for the purpose, not merely of commandeering the State funds, but of extracting specifically local contributions from all the Local Authorities who would profit, as so many of them would, in respect of a scheme of the sort which had been outlined that evening.

Mr. Jack Jones, M.P. (Mayor of West Ham), said for a great number of years West Ham had been doing its best to meet the situation. West Ham was spending on the average £5,000 per mile to maintain the roads in the particular area which Sir Henry Maybury had mentioned. Was not that a big contribution for a poor district, mainly composed of working men and women ? He had pointed out in the House of Commons that it was useless to spend millions of pounds in improving the docks if the roads leading to the docks were neglected. They in West Ham were quite willing to face their share of the responsibility, but they thought it was absolutely unfair that, simply because they happened to be right in the highway of the world's traffic, they should be asked to bear any more than their fair share. He had been told that the Victoria Dock Road was not a main road, but everybody in the East End of London knew that the East India Dock Road and the Victoria Dock Road led to India, China and Japan. They were the world's highways; they were not merely national, but inter-national, roads, and yet, when West Ham asked for help to enable them to carry out local improvements, they were refused it. West Ham was prepared to contribute their fair share to the cost, but because they happened to be a dockside district, because they happened to be not sufficiently influential to be able to impress their feelings upon those in authority, they could not be expected to foot the full bill, and an enormous bill it was.

He was sorry that Sir Joseph Broodbank had referred to the question of money. He himself would like to draw attention to the fact that millions of money were being lost to commerce and industry by the non-development of the dock roads. Another important fact was that thousands of working hours were lost in the course of a month by the labourers being held up by the swing bridges and level crossings. He asked Sir Joseph to reckon how much that cost, not to the people who could afford to lose it, but to the people who could not. The roads leading to the docks were practically bottle-necks all the way. Quite a different state of affairs existed in Liverpool, and why could not London have something of the same sort ? West Ham had been talking of Sir Henry Maybury's scheme on their Council for the past twenty years, but they had never been able to carry it out because their poverty had been their principal virtue. It was not a local question. There was an Imperial Exhibition now being held in London, and all parts of the Empire were being asked to come to it. He wanted them to come and see the Gateway of the Empire—not West Ham or Poplar, but the entrance to all the great possessions of the Empire, about which the Empire boasts so much. As he had said, it was not a local question; it was a national question, if not an Imperial question. West Ham would do its bit, and he hoped the rest of the Empire would do their bit.

Chief Constable A. Bassom (Traffic Dept. New Scotland Yard) said the present congestion was due entirely to the inadequate roads and bottlenecks. That congestion would be all the more severe when the area became more developed. He would be the first to welcome any improvement to the roads in the dock area. The broader the roads the better would be the facilities for traffic, and the less number of police would be necessary in order to regulate the traffic, which would mean a great saving of expense.

Sir Cyril Kirkpatrick (Chief Engineer, Port of London Authority) said it had been a pleasure to him to hear Sir Henry Maybury give particulars of a really big scheme which would solve for all time, in his view, the difficulties at the western end of the Victoria Docks. He knew the scheme very well. It was one in which there were no physical difficulties, except the usual one of money, but as the Chairman was taking such an active interest in the matter, he felt sure the money would be found without any difficulty. There was just one point to which he desired to refer. Sir Henry Maybury had dealt only with one end of the Docks. There was another end which was in a still worse condition, which represented a bigger job, and which would take quite as many millions in order to improve it.

Mr. G. W. Humphreys, C.B.E. (Engineer to the London County Council), remarked that for the last twenty years he had heard the scheme put forward that night discussed, and he had heard it advocated in no mean eloquence by West Ham and the neighbouring authorities before the London County Council. The answer of the London County Council had been that their interests in the matter were really bounded by the River Lea. The sympathies of the London County Council, however, had extended far outside their boundaries, and the line of communication which existed at present, bad as it was, was a line of communication which had been furnished by the London County Council, and was the only existing road to the Dominions beyond the Seas. Something had been said that night about "direct action." That was the line he would like to take—to take the scheme in hand and get it done as fast as possible if only the funds were forthcoming.

Sir John Ontario Miller, K.C.S.I., (Member of the Port of London Authority), said he was bound to say that the condition of things in the dock area was almost a scandal to the greatest city in the world. No slides or pictures could give one an idea of the amount of delay which was prevalent, and of the irritation which that daily caused. Mr. Jack Jones had referred to the way in which work-people were delayed in getting to their work by being held up at level crossings and swing bridges. Such conditions made for slovenliness and inefficiency in work. The removal of such a spirit by doing away with the obstructions which caused it would, he thought, be just as important as any of the other improvements which would be brought about by the scheme.

MR. E. B. TREDWEN (Hon. Treasurer, London Chamber of Commerce) remarked that everyone appeared to be agreed as to the absolute necessity for the improvements which had been suggested, and that it was only a question of money which stood in the way. It had been suggested that the Port of London should be asked to contribute substantially towards the expense of the scheme. He objected very strongly to that, for the reason that one of the things which at the present time was driving traffic away from the Port of London to other ports was that the charges in London were too high. The Port of London Authority was established by Act of Parliament to levy only such dues as would pay the interest upon its outlay. It was not, he took it, authorised to spend money outside its own territories and to charge the interest upon that expenditure against the goods that passed over its territories, or the ships that came into its docks. Therefore, the P.L.A. should not be asked in any way to contribute. The P.L.A. had already made a most magnificent contribution. It had built docks up to all the requirements of the Port to-day. He did not think it should have to increase its charges by making a contribution to the proposed roads, much as they were wanted.

MR. W. R. DAVIDGE, F.R.I.B.A., M. INST. C.E., said he was sorry to hear the remarks of the last speaker. It did seem to him essential that in all such matters a broad point of view should be taken. Sir Henry Maybury's scheme would be the first step to make the London Docks equal to the Liverpool Docks as far as road approaches were concerned. Although Sir Henry had referred in generous terms to the Marseilles and Havre dock roads, the roads which Sir Henry himself made were far better than the roads of the Marseilles and Havre docks. If Sir Henry brought into the present scheme the same perfection as he did with regard to his road surfaces elsewhere, it would be a very fine thing indeed.

MR. H. MARKS (Limehouse), briefly described how repairs to the roads retarded traffic and caused congestion.

THE CHAIRMAN, in moving a vote of thanks to the author for his paper, said he had the honour to be associated with Sir Henry Maybury in his work. It had not been decided how long he personally should stay in his present office, but while he was there he would certainly give Sir Henry all the help he could, in what he considered was very good work indeed. One could not be associated with transport in the sense in which he at present was without realising what a tremendous problem it was, and how remunerative it was to spend money in the way Sir Henry suggested. If one was looking for a real remunerative return for the State's money, he believed a better way could not be found than by building up the great main roads of the country and making transport easier. If that were done, so much the better it would be for industry. He did not agree with those people who were afraid to launch out in the matter. The country was suffering very badly from want of transport facilities, and the one way to encourage those who wanted to get on to the roads was to make the roads fit to get on to. It was well to get rid of the old idea that nothing should be done because a mistake might be made. It was far better to make mistakes than to do nothing at all.

The vote of thanks was then put and carried unanimously.

SIR HENRY MAYBURY, in reply, said he had taken a considerable amount of interest in the project. He had been associated with a scheme of sorts for improving the area since 1912. The audience had heard from Mr. Tredwen that, in his view, the Port of London Authority should not contribute towards the cost of the work. He was sorry that such a suggestion had been thrown out at the present stage, because to some extent it was discouraging, particularly when he remembered, as he did very well, that the first suggestion for such an improvement had come from the Port of London Authority when they approached the Road Board in 1912 and asked that Board to contribute to their scheme for improving the Victoria Dock Road. He was not, however, going to assume for a moment that he would not secure substantial financial, moral and actual support in getting the scheme through when they came to close quarters. The scheme would cost a lot of money, but, as Mr. Jack Jones had said, we could not afford not to spend the money in works of this kind. The country could not afford to have millions of money invested in those great Docks, and have the whole traffic from those docks throttled by the present wretched communications.

He was hopeful that the Chairman would not only see the scheme successfully carried through Parliament, but would have the glorious opportunity of opening the new road.

THE NATURAL RESOURCES OF HAYTI.

Although there are said to be considerable mineral deposits, it is generally agreed that the economic future of Hayti depends upon agriculture. Since the French colonial period there was, until quite recently, no organised agriculture of any kind. Coffee, the staple product of the country, grows semi-wild, and similarly cotton, the second product of importance.

In 1918 an American corporation put 2,700 acres in the St. Michel Valley into cultivation and planted a long staple cotton from seed imported from the United States of America. The first crop was attacked by boll-rot. Subsequent experiments have shown that the native cotton is not susceptible to the disease. It seems therefore, writes H. M. Consul and Chargé d'Affaires at Port-au-Prince, that the future of cotton production in Hayti will depend upon improving the native cotton.

There are plantations of sugar cane in the plains of Leogane and the Cul-de-sac. The Haytian American Sugar Company is understood to be replanting its plantations with a type of cane imported from Porto Rico which resists disease and gives a greater production to the acre. This company during the past year produced some 9,500 tons of sugar.

In June, 1923, the California Packing Corporation obtained a concession for a term of fifty years for the cultivation and packing of pineapples. Planting has already commenced in the northern plain around Cape Haitien, and it is understood that results have been encouraging.

There is no doubt that agriculture in Hayti can be greatly developed. There is scope for the employment of capital in organised agricultural enterprise, but capital is discouraged by the lack of irrigation and transport. The proposed linking up of the present isolated branches of the "Compagnie Nationale des Chemins de Fer d'Haiti" and its extension into the central plain would go a long way to remove the latter disability. Irrigation, on account of the large capital investment involved, is a far more difficult problem. At the present time only a very small part of the central plain, a plateau 1,200 feet above sea level, and the rich alluvial valley of the river Artibonite, both regions being eminently suitable for organised enterprise, are capable of cultivation.

Until some means can be found to carry out adequate irrigation projects, attention must be confined to the conservation and economical distribution of the present available water and to the improvements of the staple products. It is thought that by improvements in handling and methods of marketing the production of coffee, which already amounts to 68 per cent. of all exports, could be increased.

The production of cotton, which now amounts to 15 per cent. of all products, can be increased by educating the peasant producers into taking more intelligent care of their plants.

Logwood, the third product in order of importance, has been taken from the areas around the open ports. Until more areas are opened up and facilities for transport made available, no appreciable increase in production can take place.

The Government, realising the importance of agriculture in the economic development of the country, has appointed an agricultural adviser, nominated by the President of the United States, in accordance with the expressed objects of the Haytian American Convention, and it is proposed to establish a system of agricultural education.

MEANS OF COMMUNICATION IN KASHGAR (Chinese Turkestan).

Roads. Reporting on the trade of Chinese Turkestan in 1922-23, H. M. Consul-General at Kashgar remarks that passable roads connect all the chief towns and larger villages of the Province, and it is possible to drive in a carriage almost anywhere within the great oases of Southern Hsinkiang without much difficulty. There is of course no metalling of any kind, but as the clay soil is firm and only about one per cent. of the traffic is wheel-borne, there are no ruts: indeed many of the roads would compare not unfavourably with the average rural unmetalled road in Europe. Bridges, albeit often rickety ones, over the numerous canals and streams are kept in some sort of repair on the "begar," forced labour system; over the big rivers ferries, with barges large enough to take 100 men or 20 horses at a time, are kept up. The only drawback from the point of view of the more rapid forms of wheeled transport is the frequency of shallow irrigation channels which cross the public highway and have to be negotiated slowly. Government rest-houses (often small and jerry-built affairs, it is true) are to be found at every stage along the main routes, in addition to the local *serais*. An interesting instance of enterprise in the opening up of new routes on the part of officials is afforded by the work of Ch'en Chi-shan of Khotan, who built rest-houses along the Khotan river route from Khotan right across the Takla Makan desert to the Tarim River south of Aksu, a matter of 300 miles, without a habitation except the huts of a few wandering shepherds.

Motoring is not to be recommended in Southern Hsinkiang; even if it were possible to transport a car across the high passes and sandy deserts which defend the country on every side, the irrigation channels mentioned above as crossing the roads every few yards would be a source of irritation even in the cultivated areas, while between the oases the exceedingly fine sand of the loess desert would make progress impossible without a caterpillar wheel attachment or similar contrivance.

Postal Service. The Post Office is a well-run department and the service is regular and efficient, though rates are necessarily high. Letters take two months to reach Kashgar from Inner China, parcels four to five months. From Kashgar to Keriya, 413 miles, including 150 miles of sandy desert, the postal couriers take ten days. The service between Keriya and railhead at Pingtang, nearly three thousand miles, is by far the longest courier-borne postal service in the world. The efficiency of the postal service is the more creditable in view of the enormous difficulties the Department has to contend with. These, to quote a recent "Report on the Chinese Post Office," include "the vastness of this province of desert and mountains, the lack of reliable information, the scanty and nomadic population, the diversity of races and languages, the small proportion of the population able to read and write, the ignorance on the part of the public of postal regulations or even of the benefit to be derived from a postal service, the poor elements from which to recruit postal employees, the constant difficulty encountered not only in procuring but training couriers to to run along difficult lines through arid country where subsistence for neither man nor beast can be found, where there are dangerous rivers to negotiate, and where attacks on couriers by wandering tribes are frequent."

MEETINGS OF THE SOCIETY.

◆

INDIAN SECTION.

MONDAY JUNE 30, at 4.30 o'clock.—J. C. FRENCH, I.C.S. "The Art of the Pāl Empire in Bengal." THE RIGHT HON. THE EARL OF RONALDSHAY, G.C.S.I., G.C.I.E., will preside.

DOMINIONS AND COLONIES SECTION.

MONDAY, JUNE 2, at 5 o'clock.—THE RT. HON. SIR FREDERICK LUGARD, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member, Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates." THE RT. HON. VISCOUNT MILNER, K.G., G.C.B., G.C.M.G., will preside.

MONDAY, JUNE 16, at 4.30 o'clock.—C. V. CORLESS, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada."

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, JUNE 2 .. Geographical Society, 135, New Bond Street, W., 8.30 p.m. Messrs. R. A. Frazer and E. F. Relf, "Central Spitzbergen and North East Land."

Farmers' Club, at the Surveyors' Institution, 12, Great George Street, S.W., 4 p.m. Mr. E. H. Godfrey, "Canadian Farming, with special reference to costs of production and conveyance of produce to English Ports."

Royal Institution, Albemarle Street, W., 5 p.m. General Meeting.

Ingénieurs Civils de France, Societé des, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., 5.30 p.m.

University Extension Lectures, at Gresham College, Basinghall Street, E.C., 6.15 p.m. Mr. A. Compton-Rickett, "Personal Forces in Modern Literature." (Lecture V., O. Henry.)

TUESDAY, JUNE 3 .. African Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Captain R. S. Rattray, "Arts and Crafts of Ashanti."

Colonial Institute, Hotel Victoria, Northumberland Avenue, W.C., 8.30 p.m.

Empire Mining and Metallurgical Congress, at the British Empire Exhibition, Wembley, 11 a.m (1), Viscount Long of Wraxall, Presidential Address, "Mineral Resources and their relation to the Prosperity and Development of the Empire." (2) Reading and Discussion of Papers.

Photographic Society, 35, Russell Square, W.C., 7 p.m. Paper on "An Analysis of Motion by Kinematography."

Royal Institution, Albemarle Street, W., 5.15 p.m. Major M. S. Tucker, "Acoustical Problems." (Lecture II.)

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m. Miss M. E. Durham, "West Balkans: Old Customs connected with Deaths, Blood Vengeance, Etc."

WEDNESDAY, JUNE 4 .. Empire Mining and Metallurgical Congress, at the British Empire Exhibition, Wembley, 10.30 p.m. Reading and Discussion of papers continued.

Archæological Institute, at the Society of Antiquaries, Burlington House, Piccadilly, W., 5 p.m. Dr. P. Norman, "Additional Examples of English Medieval Alabaster Carvings."

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 p.m. "May Lecture." Dr. F. W. Aston, "Atoms and Isotopes."

University of London, University College, Gower Street, W.C., 5.30 p.m. Prof. H. Pirenne, "Les périodes de liberté et de réglementation dans l'histoire l'économique." (Lecture II.)

3 p.m. Prof. E. G. Gardner, "Problems of the Inferno of Dante." (Lecture III.)

At the London School of Economics, Houghton Street, W.C., 5.30 p.m. The Right Hon. L. C. Amery, "The Defences of the Empire."

THURSDAY, JUNE 5 .. Empire Mining and Metallurgical Congress, at the British Empire Exhibition, Wembley, 10.30 a.m. Reading and discussion of Papers, continued and concluded.

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Linnean Society, Burlington House, Piccadilly, W., 5 p.m.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m. (1) Messrs. T. M. Lowry and H. S. French, "The Absorption Spectra of Camphor and of Camphorquinone." (2) Messrs. H. Burgess and T. M. Lowry, Studies of dynamic isomerism. Part XVI. Mutarotation of beryllium benzoylcamphor. Formation of an addition-compound with chloroform. The optical activity of beryllium.

Royal Institution, Albemarle Street, W., 5.15 p.m. Professor C. G. Seligman, "The Veddas of Ceylon."

University of London, University College, Gower Street, W.C., 5.30 p.m. Professor H. Pirenne, "Les Périodes de liberté et de réglementation dans l'histoiré Economique." (Lecture III.)

At King's College, Strand, W.C., 5.30 p.m. Professor A. J. Toynbee, "Outlines of Byzantine, Near Eastern and Modern Greek History. (378-1841 A.D.)"

FRIDAY, JUNE 6 .. Royal Institution, Albemarle Street, W.. 9 p.m. Lord Rayleigh, "The Glow of Phosphorus."

Philological Society, University College, Gower Street, W.C., 5.30 p.m. "Dictionary Evening."

SATURDAY, JUNE 7 .. Royal Institution, Albemarle Street, W., 3 p.m. Mr. C. Nabokoff, "The Historical Trilogy of Count Alexis Tolstoi."

Journal of the Royal Society of Arts.

No. 3,733. VOL. LXXII.

FRIDAY, JUNE 6, 1924.

28 AUG 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

DOMINIONS AND COLONIES SECTION.

TUESDAY, MAY, 27th, 1924; DR. J. W. EVANS, C.B.E., F.R.S., President of the Geological Society, in the Chair.

A paper entitled "A Sketch of the Geology and Mineral Resources of Cyprus" was read by Mr. C. Gilbert Cullis, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology.

The paper and discussion will be published in a subsequent number of the *Journal*.

TWENTY-THIRD ORDINARY MEETING.

WEDNESDAY, MAY 28th, 1924; LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The following candidates were proposed for election as Fellows of the Society:—

Coriell, Louis Duncan, Baltimore, U.S.A.
Durran, William, London.
Oxley, Oswald John Philip, Durban, South Africa.
Raju, M. G., A.M.I.E.(Ind.)., Madras, India.

The following candidates were duly elected Fellows of the Society:—

Angle, Edward John, M.D., B.Sc., A.M., Nebraska, U.S.A.
Birch, Prof. T. Bruce, A.M., Ph.D., Springfield, Ohio, U.S.A.
Else, J., R.B.S., Nottingham.
Hansard, Colonel Arthur Clifton, C.M.G., London.
Henderson, Francis, J.P., Tunbridge Wells, Kent.
Hertz, Jacob, London.
Holdengarde, Theodore Albert Edward, Bulawayo, Rhodesia, S. Africa.
MacGallavry, Robert, Java, Netherlands East Indies.
Shehata, Nasif Girgio, Birmingham.

A paper on "The Position of the Arabs in Art and Literature" was read by MRS. ARTHUR MCGRATH (Rosita Forbes).

The paper and discussion will be published in a subsequent number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

FRIDAY, MAY 2ND, 1924.

SIR THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., D.Sc., F.R.S., Rector, Imperial College of Science and Technology, in the Chair.

THE CHAIRMAN, in introducing Professor Thorpe, explained that in 1918 the Indian Industrial Commission had arrived at the conclusion that no policy intended to foster industrial development in the country would have anything like an appreciable result unless it were preceded, and for that matter accompanied, by the active organisation of public services designed for conducting research work, especially on the raw materials of the country, as well as for the investigation of processes suitable for commercial development under Indian conditions. The Geological Survey of India was founded in 1850, and had demonstrated quite clearly that its cost was a profitable investment to the Indian taxpayer. There were also smaller services for botany and zoology, and their institution had proved equally wise. Nothing, however, had been done on systematic lines for chemistry, and on chemistry many of their industrial enterprises were based. They of the Commission had not felt justified themselves, for want of technical qualification, in going further than to sketch out the broad lines of advance, proposing that their suggestions should be criticised, and, if found to be generally suitable, should be elaborated by specialised committees. Those proposals had been accepted by the Government of India, and the Secretary of State had been asked in 1919 to select some suitable authority in this country to act as president of a committee of enquiry with regard to the development of chemistry. The chemists who were present that afternoon would agree that the Secretary of State had made a very wise selection in asking Prof. Thorpe to undertake that work, and personally he would like to say that the Imperial College had shown their regard for imperial interests in sparing Prof. Thorpe's valuable services. Prof. Thorpe's position as a distinguished research worker and teacher, and his familiarity with problems of a similar nature as a member of the Advisory Council for Scientific and Industrial Research, gave him very special qualifications for a task of that sort, and as the member of the Government responsible for the Department with which Prof. Thorpe worked, he could testify to the thorough and conscientious way in which Prof. Thorpe had tackled the question when he arrived in India.

The paper read was :—

CHEMICAL RESEARCH IN INDIA.

By Jocelyn F. Thorpe, C.B.E., D.Sc., Ph.D., F.I.C., F.R.S.,

Professor of Organic Chemistry, Imperial College of Science and Technology.

The Indian Industrial Commission, presided over by Sir Thomas Holland, issued its report in 1918. It had been formed in 1916, and was "instructed to examine and report upon the possibilities of further industrial development in India, and to submit its recommendations" with special reference to a number of specific questions, of which two only concern the subject of this paper. These were "(b) to ascertain whether and if so in what manner, Government can usefully give direct encouragement to industrial development—

(i) By rendering technical advice more freely available :

(ii) By the demonstration of the practical possibility on the commercial scale of particular industries.

The Report, which is an admirable summary of the present day conditions in industrial India, concludes with the following paragraph, which I cannot do better than quote, and adopt as the text of my paper this afternoon—"We have briefly sketched the lines of economic development along which India has moved since she first came into contact with western traders ; and have described in more detail the commercial and industrial position to which these lines of development have led her. We have shown that this position has become in many ways disadvantageous to the interests of the country ; and that India's industrial equipment is impaired by deficiencies which affect the interests of national safety. The industrial system is unevenly, and in most cases inadequately, developed ; and the capitalists of the country, with a few notable exceptions, have, till now, left to other nations the work and the profit of manufacturing her valuable raw materials, or have allowed them to remain unutilised. A powerful and well-directed stimulus is needed to start the economic development of India along the path of progress. Such a stimulus can only be supplied by an organised system of technical, financial, and administrative assistance."

The commission made a number of recommendations dealing with the various items of its remit. It recommended, for example, the formation of several scientific services built up on lines which, it was hoped, would give an impetus to the development of industries based on the great natural resources of the country, for it was evident, as the passage quoted above shows, that the absence of any organised system of scientific research was the reason why many of these resources remained unexploited, and that, even where an industry had been established, had caused the principles on which it was based to be of the "rule of thumb" order without adequate regard to the scientific factors involved.

Among the services the formation of which was recommended was one dealing with chemistry, and, as this subject was rightly regarded as one of the foundations of all industrial development, the first effect given to the report of the Commission was to appoint a committee with instructions to "formulate proposals for the organisation of a Chemical Service for India and for the location and equipment of research laboratories." I was asked to act as Chairman of this committee, and with the object of obtaining an insight into the actual conditions, I toured through India during November and December of 1919 and January and February of 1920. In the course of the tour I visited all the important centres and was able to discuss the problems involved with many prominent officials and business men. I saw all the leading educational institutions and noted the facilities for research present in the chemical departments attached to them. It is evident that if an attempt is to be made to outline a scheme by which the industrial chemical needs of a country such as India are to be met, and an organisation for the purpose developed and maintained, it is necessary in the first instance to ascertain the condition of the scientific personnel from which recruits could be drawn to act initially as research workers in the service, and ultimately rise to the positions of directors. For one of the chief objects in view, besides ascertaining the best conditions for the establishment of the chemical service, was to find whether such a service could be expected to become self-contained, from the Indian point of view, in the near future. For, although it was evident that a start would have to be made with an admixture of chemists possessing a European training, it was hoped that in the course of a few years the methods of scientific training carried out in the Indian Universities would have so far improved as to render it possible for them to supply an adequate number of fully qualified Indians for recruitment into the service. There is, in my opinion, no reason why the recruitment to the suggested service should not be wholly Indian in the near future, although I fear that for many years it will be necessary for the recruits to have at least one year's training in Europe prior to enlistment. Until education in India has improved it will, therefore, be necessary for the State to provide scholarships for carefully selected graduates to enable them to obtain this training. It seemed to me that many of the Indian Universities provided an adequate course of training in general chemistry, their M.Sc. degree being comparable with our B.Sc. Honours degree, but they are too busy preparing for the inevitable examinations to take much trouble about the need for a research training. No doubt facilities exist, but the teachers who should act as trainers in research are apparently overburdened with administrative and teaching duties, and cannot afford the time to carry out research even of the simplest kind. If India is to supply its own research chemists, the Universities must not only adequately train their chemistry students in the principles of chemistry, but must also, after graduation, provide a training in research methods of at least one or two years duration. The so-called technological institutes cannot help, because they are mainly trade schools in which certain branches of trade technique are taught. The subjects in which the students are instructed are usually connected with the industries of the district, and although there can be no question that these institutes are doing valuable and useful work, it is not likely that they will foster fundamental research, indeed it is not desirable that they should do so, for it is important that the student should receive his research training in some subject of general interest without direct commercial bearing. I know that many chemists do not agree with me on this point, but, the longer experience I gain as the head of a large research school, the more I realise that I am right, and that the introduction of research, likely to have a monetary value, into a research school develops and fosters cupidity, secretiveness, and every other anti-scientific vice. "Avant tout, développons l'âme scientifique avant de plonger le corps dans l'océan du commercialisme" is an extract from the preface to a recent French book, which is perhaps appropriate.

It will be seen, therefore, that India is at present poorly equipped to meet any demand for properly trained chemists, and cannot be expected to supply recruits for a chemical service unless, as mentioned later, the service itself can act as the research trainer. Nevertheless, the picture is not entirely dark, as it is possible that the Indian Institute of Science at Bangalore may, under the new régime, revert to its original purpose, and become the centre of research training in India. The Institute was originally projected by the late Mr. J. N. Tata with the object of encouraging post-graduate research in pure physical science, and, with this object in view, it was designed and equipped under the auspices of the late Sir William Ramsay. When I visited the Institute at Christmas, 1919, it was evident that the research work being carried on was mainly of a commercial character, and it was apparent that the original intention of the founder was not being carried out. Recently, a committee under the chairmanship of Sir William Pope has framed a scheme for the reorganisation of the Institute, and there is every reason to believe that, if the new organisation is found to be successful in practice, the Institute will become of real use to the Indian Empire, and will be of the greatest value in the development of several of the scientific services proposed by the Industrial Commission.

The conditions in the Universities are, I fear, not likely to improve if the evidence given before my Committees, by the Educational Commissioner with the Government of India, represents the settled and considered opinion of the educational authorities. This gentleman in his written evidence stated that —

> "The College Professor has little or no time for research, and the chief Professors, who may be styled University Professors, will be largely in the same position."

> "In India a member of a College staff is generally burdened with the multifarious duties of College organisation."

These statements provide a full and sufficient reason for the fact that, hitherto, real university scientific work in India has been almost non-existent, and it is regrettable that such a state of affairs should be acquiesced in by those responsible for the educational policy of the country. It is significant that no chemist in India holds the Fellowship of the Royal Society. As a matter of fact the amount of new chemical knowledge emanating from India is exceedingly small, and out of all proportion to the number of University teachers and students, and the size and equipment of the University chemical laboratories. Apart from the output from the Government Departmental Laboratories of Agriculture and Forestry, to which reference will be made later, the only institutions carrying out publishable research are the College of Science, Calcutta, the University of Dacca and perhaps one or two others. The need for reorganisation is therefore urgent.

The general scheme outlined in the Report of the Industrial Commission for the establishment of a chemical service provided for the formation of a central research institute under the Government of India. The suggested organisation is given in the following paragraphs quoted from the report—"Taking Chemistry first, it would be possible, for administrative purposes, to divide the chemists into three fairly compact groups, which might be called, (*a*) agricultural, (*b*) organic and (*c*) mineral chemists. In many way the agricultural and the organic chemists would overlap, as many of the problems of agricultural chemistry are organic in character. It is desirable, however, in a country such as India, where agriculture is so extremely important, to give this branch of chemistry special consideration. The organic chemists would be occupied largely with problems connected with forest products, drugs, perfumes, essential oils and dyes, leather and sugar. Many of these officers would be eligible to officiate in the agricultural group. The mineral chemists would include metallurgists, the metallurgical inspectors and the chemists of the mints and Geological Survey. At some laboratory recognised as the headquarters of the service there should be at least one chemist who has specialised in physical chemistry, for a chemist of this type would deal with the physical problems connected with both the inorganic and organic substances. It seems to us that Dehra Dun possesses many advantages as a site for the headquarters of this as well as of other scientific services. The whole of the chemists would be under the control, for scientific purposes, of a senior officer, who might appropriately be called the Chief Chemist to the Government of India. Under him directly would be the staff of the headquarters laboratory, including the physical chemists and the specialists not assigned to provincial branches. The other three groups would be under the supervision of three Deputy Chief Chemists. Junior members of any of the three groups would be lent to Local Governments and the principal Government Departments for terms normally limited to five years. They would carry on the routine duties required, in some cases including teaching, and would undertake certain forms of research with the approval of the head of their service. All the results of scientific and practical value would be published in a serial recognised as the authoritative publication of the Indian Chemical Service. Such a serial would quickly establish its position in the scientific world, and would become a convenient medium for the publication also of papers by private chemists, resulting in the formation of an Indian School. At convenient intervals, most or all of the chemists might assemble for a week's conference, which should be open also to manufacturing and private chemists."

It will be seen, therefore, that the scheme as suggested by the Industrial Commission was a comprehensive one, and well fitted to meet the immediate industrial requirements of the country. It provided for the establishment of a central Government research institute at which both fundamental and practical research would be carried out, and which would serve as a nucleus from which chemists could be drawn to fill the various chemical posts throughout the Empire. There is little doubt that such a scheme would have been workable in practice for it was built on sound general lines and provided for practically indefinite expansion as occasion required.

Nevertheless, it was evident to me during the course of my tour that the Provinces would have nothing to do with such a scheme. Each and all of them were keenly alive to the needs of the times. They recognised the necessity for scientific investigation into the conditions underlying their existing industries, and were fully aware that many of their natural resources remained undeveloped and could only be developed through the agency of scientific research, but they wished to do these things on their own behalf, unhampered by any restrictions which might be exercised by a central Government institution such as that suggested by the Industrial Commission. It was clear, owing to the strength with which this view was held, that any attempt to press the proposed organisation would have been attended with failure, and that the original scheme would not only have to be modified, but extended so as to provide for the establishment of a research institute in each Province.

Still, an extended scheme by which each Province would have its own research institute seemed practicable and, indeed, even an improvement on the original idea, provided that each Provincial Institute undertook to confine its activities, both fundamental and practical, to its own local immediate industrial needs, leaving a central institute under the Government to carry out those fundamental researches which underlay the industries of the country as a whole. A modified and extended scheme of this kind was recommended in the report of my Committee. In practice the Provincial Institutes would carry out research work on questions submitted to them by manufacturers in the Province, and would also carry out research work on new industries, likely, owing to the presence of the raw material in the Province or for other reasons, to be effectively established there. In England, two very strong and reasonable objections would be at once raised to such a scheme. The first would be that the proposed organisation would take away the livelihood of a number of useful consulting chemists, the second that it would provide the manufacturer with an excuse for not doing what, in his own interests, he ought to do, namely to establish and maintain a research laboratory of his own. But England is not India, and conditions which are present in the one country are absent in the other. No one would for one moment imagine that an organisation such as that outlined above would have the remotest chance of being successfully worked in England, where the conditions of manufacture are highly organised, and where most firms maintain research laboratories for their own purposes. Moreover, when any problems arise on which firms in England require expert advice, not forthcoming from their own research laboratories, they have at their command the services of a host of consulting chemists dealing with almost every branch of the science, and they can, if need be, ask the advice of one or other of the many experts dealing with special subjects in the Universities and University Colleges. There are, however, very few consulting chemists in India, most of the consulting advisory work, where such exists, being carried out in the Universities.

The second objection, namely, that the manufacturers might be induced, were the scheme to come into operation, to abandon or refrain from establishing research laboratories in their own works, would also not apply to Indian conditions. Indeed, the successful working of the proposed organisation would, in all probablity lead to an effect precisely opposite in character. Very few manufacturers in India maintain a staff of research chemists, and those that do would naturally only apply to the Provincial Research Institute for the solution of such problems as their own staffs had not the skill or time to attack. Work of this kind would, of course, have to be paid for by the manufacturers on an agreed scale of charges, but the chief and most important outcome would be, that the chemist or chemists who had solved the problem in the research institute would be loaned to the manufacturer for a sufficient period of time to enable them to place the new process on a working basis in the factory. In the case of a new industry, which might have been either initiated in the Provincial Research Institute itself or have been sent down from the central Government Institute for development, the Provincial Institute, after working out the details on the laboratory scale, the semi-large scale and the "unit" factory scale, would ascertain whether any existing firm of manufacturers were prepared to take over the process. If this was not possible, steps would be taken to find if any capitalists would form a syndicate to finance a new company for the purpose of starting the industry. Here again the chemists engaged on the new process would be transferred to the firm or syndicate for an agreed period of time, but they would retain a *lien* on the service for a certain number of years, unless in the meantime they desired to become actual employees of the manufacturers, in which case they would pass out of the service with such pension as their position in the service provided.

The general effect would thus be to establish a research laboratory in the factory or to augment it if one already existed. The scheme would not in any way prevent manufacturers from carrying out "secret" research on problems connected with their own products, because this would be done in their own laboratories by their own chemists. The question of cost would have to be determined by agreement, but it would be the aim of the institute not to charge more than the actual cost price of the investigation, the object being to create new industries and to improve old ones for the general good of the country, and not to enable the institute to make any financial profit. The salaries of the transferred chemists would be paid by the manufacturers so long as they remained in their works; and every facility should be afforded to the chemists to pass from the service into the industry, for it is only in this way that the industry can become ultimately self-supporting, an object it is one of the purposes of the proposed service to achieve.

It might be thought that many of the investigations into the establishment of new industries would be, so to speak, "in the air," that the institute might find itself saddled with a number of completed investigations for which no market could be found, and which would thus remain unexploited; for one of the essential features of the organisation would be the avoidance of any semblance of competition with private commercial enterprise, its primary duties being to establish and assist, but, in no case, to compete with private effort. In practice, however, there is little doubt that no such difficulties would arise. The field to be investigated is an enormous one and there are numerous problems awaiting attack. There is no doubt that before any investigation was undertaken by the Institute, care would be taken to ascertain not only that the proposed new industry was based upon sound economic grounds, but also that, if successful, the necessary capital would be forthcoming to exploit it commercially. It might also be urged and was, indeed, so urged by Sir P. Rây in the note he appended to the report of my committee, that all the best men would pass out of the service into the industry, and that the Chemical Service would thus become a dumping ground for the incompetent, who would remain until they had completed their thirty or so years of service and then retire with a more or less adequate pension. This is, of course, a real objection, but it is one which has to be faced by every organisation which aims, as the Chemical Service would aim, at the improvement and development of the scientific status of a country. Those of us who spend our lives teaching research methods in our Universities and in our University Colleges have to reconcile ourselves to the inevitable fact that our best men leave us so soon as they have learnt our methods and have absorbed all that we can teach them. This does not mean that we are inefficient, on the contrary, it means that we are carrying out our work effectively. It is our business to instruct and lose, hoping that the source of supply will not fail to provide other good men equally competent to profit by our teaching. It is true that in our case the weaker men pass into minor posts and do not remain a burden on our hands, and to avoid this in the case of the proposed Chemical Service the Committee recommended the establishment of a stringent "efficiency bar" which would lead to the compulsory retirement of the hopelessly inefficient after a definite period of service. The success of the service would be determined by the rapidity with which men passed from the Universities into the service and thence into the industry.

In the Central Government Institute organised research of a fundamental character would be carried out. Much of this would arise during the operations conducted at the provincial institutes and would be referred by them to the central research institute; such reference would, however, only be made when the problem was either of general interest to the whole Empire, or, while fundamental in character, did not give promise of sufficiently quick practical results to warrant the provincial institute in attacking it. The decision on this point would rest with the provincial institute. It would be one of the chief duties of the Central Government Institute to survey the industrial possibilities of the Empire generally, and to initiate research having for its object the establishment of new industries in different parts of the country. In many cases, investigations such as these would be handed over at an early stage to the particular provincial research institute in whose district the best facilities for the establishment of the industry existed, but in some instances, where the research was one of general interest to the whole Empire or of national importance as a key industry, the attack on it would be carried out by the central institute.

It will be seen, therefore, that the scheme suggested provided for the establishment of two very similar types of institution. One type, situated in each of the most suitable provincial centres, would be essentially practical in outlook. The other, situated at some convenient central place—the recommendation of Dehra Dun for this purpose by the Industrial Commission was endorsed by my Committee—would conduct research mainly fundamental in character, but would, nevertheless, deal in certain cases with investigations involving the practical establishment of a new industry. One of the main advantages of this arrangement would be that the personnel could, to a certain extent, be interchangeable, a most desirable feature when it is remembered that each institution must necessarily act as a training centre for the personnel it employs. No University or Technological system of training can be expected to discriminate between the men who are best fitted to act as leaders of research and those who are suited by natural characteristics and temperament to be leaders in the conduct of works practice. It is essential, where chemical manufactures are concerned, that each type of man should have received the same grounding, and this is adequately effected by a system involving a course of instruction up to the Honours graduation stage, followed by a training in research methods, the latter serving to impart the feeling of self-reliance and patience essential to success in a chemical worker, which cannot be obtained otherwise. It is the final problem, that is, how to supply the training in works practice, and, what is still more important, how to pick out the men most suited by temperament to profit by this training, which has to be solved not only in India but in this country also.

It is useless to expect any University or Technological Institution, however well equipped, to supply this training. Even if such an institution were provided with a complete equipment of the most up-to-date machinery of every conceivable kind, the mere working cost of instruction with such machinery would be prohibitive. Neither is it of advantage to label students chemical engineers or engineering chemists, because such terms not only help to accentuate the supposed difference between a "pure" and an "applied" chemist, but lends colour to the view that it is possible under our present system of education to produce such a hybrid. Chemical engineers are usually engineers masquerading as chemists, rarely chemists who are competent engineers.

In the proposed chemical service this very real problem of type would be met by a frequent interchange between the individuals comprising the junior personnel of the research staffs of the various institutes. Each man would, therefore, obtain his training in works practice, and if my experience as a teacher stands for anything, I am convinced that such training would serve as a method by which the men could be separated into two distinct classes, namely, those having a practical bias, and those whose instincts led them to take up work of a more fundamental character in the laboratory. The advantage gained by men working in the research laboratory by having received this practical training is obvious. Each man would be able to render himself intelligible to his fellows, and the "pure," that is, the research chemists, and the "applied," that is, the works chemists, would not be placed in their own water-tight compartments, as is, unfortunately, too often the case at the present time.

Each Provincial Institute, as well as the Central Government Institute, would, therefore, be provided with a main general research laboratory equipped in the usual manner, a semi-large scale laboratory provided with small scale plant suitable for making material on, say, the 10 lbs. scale, and another laboratory where the "unit" scale plant could be erected. It is probable that the two latter types could be combined into one laboratory. All that is required is an open floor space on which plant can be built up and pulled to pieces at will; it would have to be provided with the usual services of gas, water, etc. These proposals imply that, besides the main chemical staff, each institute would have to be provided with a suitable staff of engineers, whose main duty would be to act as instructors in general engineering practice. It is not considered necessary that the chemists forming the service should possess more than a working knowledge of engineering. A complete knowledge of both engineering and chemistry, desirable though it undoubtedly is, would be impossible of attainment in the time an ordinary individual can devote to his education. Moreover, it is unnecessary, because all that is required is for the chemist to possess a sufficient knowledge of engineering science, especially of machine drawing and workshop practice, to enable him to make himself intelligible to an engineer or draughtsman. In my opinion, it is essential that every chemist should possess such a working knowledge of engineering. It is, however, astonishingly difficult to get teachers of engineering to see this point of view. There is no difficulty in making them realise that no harm is done to an engineer by giving him a working knowledge of the principles of chemistry, but when it is suggested that a chemist would be benefited by a similar amount of engineering knowledge, it is usually stated that the training of an engineer takes at least three years, and cannot be effected in any shorter period.

Fortunately, during my Indian tour, I was able to find in the College of Engineering at Poona an institution which did not take this view, and which was prepared to give the chemists preparing for the chemical service an adequate instruction in engineering extending over a period of six months.

This matter is of such importance from the point of view of the general education of the chemist, not only in India but in this country as well, that I venture to quote from the letter written by Mr. C. Graham Smith, the Professor of Engineering at Poona, on the subject—"I was impressed with the arguments of the Committee that came to the College of Engineering the other day, in which they considered that the chemist could learn all that was necessary in a short course covering a period of, say, six months. I have discussed the question with a number of men, and none of them considered that a course of six months was sufficient, but on examination, they came round to the conclusion that what was required could be done in the period already stated. The time available might be divided more or less as follows—15 per cent. carpentry, 35 per cent. engineering shops, smithy, etc., 20 per cent., sketching, and 30 per cent. mechanical and elementary drawing, making in all 50 per cent. shops and 50 per cent. drawing.

The proposed scheme for the establishment of a chemical service would have to start in a small way, and, no doubt, in many of the Provinces use could be made of some existing institute to act as the provincial research institute, until funds were available for the erection and equipment of a building especially designed for the purpose. The executive committee controlling the service would have to be a representative body, because it would be on its recommendation that the chemists to the various Government Departments would be appointed. It should comprise the chief chemist of the various Provincial Institutes with the chief chemist of the Central Government Institute as Chairman. This body should be able to make all the recommendations necessary for the working of the service direct to the Government concerned. The chief initial cost would be incurred by the erection and equipment of the new Government Research institute at Dehra Dun, but it is understood that some of the money, at any rate, has been allotted for this purpose. Indeed, it is likely that a large capital expenditure and a considerable income would be necessary in order to start the scheme and to place it initially on a sure financial basis, because, as has already been mentioned, it is not proposed that any attempt should be made to make the Service self-supporting, and the equipment of the new laboratories would have to be completely up-to-date. No doubt a considerable annual income would be ultimately obtained by the sale of new processes and improved methods of manufacture to firms and syndicates, and this amount would be set against the annual cost of each institute, but it would not be large enough to do more than defray the partial cost of maintenance, and a considerable annual grant would be necessary in addition. Nevertheless, if the Service is to succeed, the Government must take the long view, and bear in mind, chiefly, the increase in wealth to be obtained by the development of the natural resources of the country. The opportunity is a splendid one, but to take advantage of it effectively requires courage and vision.

Sir Prafulla Rây, who framed a note to the Report of my Committee dealing with the objections from his point of view to the proposed service, commented on the undesirability of introducing yet another service into the conduct of Indian affairs. This is a point on which I am not competent to express any opinion of value, but I have noticed among my Indian students an astonishing unanimity in their desire to enter a Government Service at the earliest possible moment. I have not hitherto ascribed this wish on their part to the desire to obtain, as Sir Prafulla suggests, a "soft job" in which they can be "easy going" and "secure of drawing their monthly cheque," because it has always seemed to me that the competition for advancement must always be just as keen within a service as outside it. Is it not true, rather, that this desire to enter Government employ is due to the lack of stable conditions in India, to the absence of security of tenure, and to the impossibility of obtaining a post outside the Government service likely to yield an assured income? It is conditions such as these which also prevent the best Indian brains from adopting a chemical career in the Universities, and lead them to take up one or other of the more lucrative professions. Surely an organised service, such as the proposed Chemical Service, would not only provide a means of secure employment for chemists, but would also, by absorbing a constant stream of recruits from the University laboratories, tend to raise the standard of teaching in these institutions. Sir P. Rây thinks that the only solution of the Indian industrial problem is to be found in the old method, by which new industries are started by the importation of some expert or experts from abroad, and this method is undoubtedly a good one when the proposed new industry is based upon known knowledge, and when firms can be found abroad who are willing to part with their experts for the purpose of instituting a rival industry in another country. It is a method the possibilities of which would have to be explored by the proposed Chemical Service. But it must be remembered that the chemical industry is not like, for example, the cotton industry, in which the large firms of manufacturing engineers find it to their advantage, in order to sell their machines, to see that their clients are fully instructed in their use. In the chemical industry the men who really know are either retained by the manufacturing firm abroad or are bound to them by agreements, which prevent them from transferring their knowledge elsewhere. I am at one with Sir P. Rây in thinking that the institution of a chemical service such as that proposed would be the worst possible solution of the problem in a country in which the conditions of manufacture were developed, but I am convinced that it is the only solution possible under Indian conditions. India requires team work, and organised team work is, in my opinion, the only method which will bring about the desired result. For the natural resources of India are such that there is no reason why she should not take her place among the chief commercial nations of the world.

One has only to realise the results which were obtained during the war by the Indian Munition Board to understand the effect which organised scientific team work is likely to have on the Chemical Industries of the country.

Another objection raised by Sir P. Rây was that the proposed organisation would be top heavy; but this is, of course, inevitable in the circumstances, at any rate, to commence with. If the general scheme were adopted the first action would be to appoint the Director of the Central Government Institute and a Director for each of the Provincial Institutes, who would be responsible for elaborating the details of the scheme; they would have to appoint their staffs and erect or adapt their laboratories.

It is inevitable that an organisation such as this should be built from the top downwards. His objection as to cost I have already dealt with; the scheme would undoubtedly be costly in the initial stages, but the return would, in my opinion, be a hundredfold.

The industrial resources of India, so far as her chemical industries are concerned, may be classified under two heads, namely, those derived from mineral sources, and those based on substances which are of vegetable origin. Excepting in so far as coal and its products are concerned, the former belong to the sphere of inorganic chemistry, the organic raw materials being those which are obtainable from coal and oil, and from the wide range of substances present in the forests, and also those obtainable from agricultural sources.

The nature and extent of the mineral deposits of India have been systematically examined by the Geological Survey, but except in very special cases, the survey has not been carried to a point which would warrant commercial exploitation. It would be one of the first duties of the proposed chemical service to carry out, in conjunction with the geologists, a thorough survey of the possibilities underlying the commercial exploitation of several mineral deposits, a description of which will be found in the Report of the Industrial Commission. India is by no means deficient in the raw material necessary for the production of the essential heavy chemicals, sulphuric, nitric and hydrochloric acids and caustic alkali. It is true that sulphur does not occur native, but a wide source of this element exists in the zinc blende mines of Burma, which have not, however, yet been exploited for this purpose. Sodium chloride and nitrate are abundant, and no doubt the electric power schemes which are now being developed in southern India and elsewhere will lend themselves in due course for the preparation of nitrogenous products from atmospheric nitrogen. The salt deposits of the Kharagoda district, north of Bombay, which have recently been analysed, indicate a possible source of potassium and bromine which should clearly be explored.

The two chief Departments which have hitherto carried out chemical research in their respective spheres are the Department of Agriculture and the Forest Department, and great improvements have been effected under their auspices. The scientific officers attached to the Agricultural Research Institute at Pusa include mycologists, economic botanists, entomologists, bacteriologists and chemists. In addition there are one or two recognised agriculturists in each province. At the time of my visit I was greatly struck with the thorough manner in which the various problems being dealt with at the Pusa Institute were being attacked, and with the character of the work which had already been accomplished. The Industrial Commission in discussing its plans for the formation of scientific services, points out, however, certain disadvantages attaching to an organisation such as this, in which the subject and not the science is the bond, and the question is one of considerable interest in connexion with a subject such as Agriculture, which includes a number of sciences belonging both to the physical and biological sections.

The war brought to light the great value of team work both in India and at home. The wonderful developments accomplished then and the great results achieved by the chemists in both countries are now matters of common knowledge. In this country we have taken the lesson to heart, and already many of the fundamental problems underlying our industries are being attacked by Research organisations formed for the purpose by the manufacturers concerned. The national well-being of India demands that every effort should likewise be made on her behalf to promote research in science, in order that her existing industries may be stabilised and her great natural resources developed.

In these days of specialisation there is always a danger that the specialist may lose touch with the general advance of the parent science, and, while this is probably not a great disadvantage when the ordinary problems of, say, agriculture are being attacked, it becomes a grave handicap when research, based on the most recent knowledge, has to be carried out in order to settle or establish some fundamental question or principle. There can be no doubt, therefore, of the advantages attaching to a system by which chemists, skilled in some particular branch of chemistry, could be lent to the Agricultural Department for the purpose of investigating some particular problem in the solution of which their special knowledge was needed. In these circumstances, the Department would not merely have to rely on the services of a few men whose training and experience might or might not fit them for the purpose in view, but would have the whole strength of the Chemical service to draw on in order to obtain the right man. It seems, therefore, definitely desirable that the chemists of the agricultural service should belong to the Chemical Service.

The Forest Department is in much the same position. The Forest Research Institute is at Dehra Dun, and here, as at Pusa, a number of scientific officers carry out research work in their own subjects. The chemical products are of great variety and extent, and would well repay the cost of a staff of investigators many times the size of that at present at work. Already much has been done both as regards commercial exploitation and scientific research, the former being illustrated by the resin and turpentine factory at Jallo, and the latter by the recent discovery of carene, in the turpentine oil derived from the Pinus Longifolius, by Simonsen. But the possibilities of further development are enormous, and include the search for and extraction of plant alkaloids, the utilisation of the forest grasses for fermentation purposes, and the commercial exploitation of the vast number of essential oils which everywhere abound. These problems require the services of a number of specialists for their solution, and it is only by means of a chemical service that such specialists could be supplied.

The chief source of coal occurs in Bengal and Bihar, but only about 5 per cent. of the yearly output is available for use as coke, and, therefore, for the preparation of by-products. When I visited the Tata Iron and Steel Company's works at Jamshedpur, the recovery plant was not yet built, and coke was being made in non-recovery Coppee ovens. Since then, I believe, a complete recovery plant has been installed, and many valuable by-products must now be available for use in the organic chemical industry.

DISCUSSION.

THE CHAIRMAN (Sir Thomas H. Holland), said the paper, for the purposes of discussion, fell naturally into two main divisions. First of all there was the general relation of research and chemistry to the development of chemical industries, and, secondly, there was the application of Prof. Thorpe's principles to the special conditions of India.

Before inviting discussion he desired to refer to the special conditions which the Industrial Commission had in mind when they made their original suggestion in 1918. One part of the question had already been dealt with by Prof. Thorpe, who had explained that the existing special conditions of India necessitated direct Government activity in organising research rather than the indirect subsidy of University institutions, such as we were accustomed to in this country. Those who had criticised the original proposals of the Industrial Commission had had in mind their experience of institutions here, where private enterprise and local effort had always preceded Government activity and Government recognition. The chief fault in the criticisms that had been made here, as well as those which had been made in India, had been due to a failure to distinguish between the terms "Service" and "Department" —a distinction which had been very carefully preserved by the Industrial Commission in their Report, and especially by the Government in formulating the terms of reference for Prof. Thorpe's Committee. As a member of a service, an officer had certain covenanted privileges of pay and of pension, and, in the case of an All-India service, of prestige. That last feature had a market value even among devoted scientific workers. As a member of a department an officer was subject to discipline in his work. His body belonged to the Department and his soul to the service; but Local Governments, especially under reformed conditions, preferred scientific officers to be theirs, both body and soul. The Industrial Commission had proposed that a member of the All-India Chemical Service should be lent to Local Governments or to special departments for periods or for a special line of investigation, to be returned if found unsuitable, or to be transferred to other parts of India in order that the requirements of the chemical research work, for which they were specially fitted, might be carried on, and that they should not become limited by simply local conditions. In order to form some idea of the existing conditions of service for a chemist in India, he would like the audience to read paragraph 118 of the Industrial Commission's Report, where they would find a list of the chemists who were employed in India in Government service. They occurred in ones and twos, very rarely in threes, with a total of about 60 chemists altogether. They had to act as handmaidens to various departments, some under scientific officers (but very rarely), and others under officers who had no interest whatever in scientific research. Most of them were required to give authoritative advice on every branch of chemistry. They were in absolutely isolated posts, generally with no official prospects of promotion, and no possibility of obtaining a position which should suit and satisfy any man of energy, ability and reasonable ambition. It was at present in those circumstances utterly impossible in India to obtain a collective opinion on any chemical question. If one compared those conditions of what one might easily call a state of organised confusion with the conditions under which geologists were employed, one found that the geologists were organised in a service which was also at the same time a department. That department of officers was under the control of a director, who was one of their own caste. He occupied *ex officio* an honoured position as one of the four principal Geological Survey Directors of the world. As a result of the unity of his department and service, and as a result of the organisation of that department, the officers had the work they were fitted to do—a palaeontologist did palaeontology and a mineralogist did mineralogy. It was possible for any one, whether a Government department, or a private person, to obtain an authoritative opinion through the Director on any geological question in India. That was not possible at present with regard to chemistry. The Geological Survey of India had issued its serial publications of memoirs and records for the past 70 years, and, by the exchange of those publications with scientific institutions in other parts of the world, it had now established for its special use in Calcutta, and without any additional funds being spent in the purchase of books, one of the finest geological reference libraries outside Washington.

One of the members of Prof. Thorpe's Committee had criticised the proposal for an All-India Chemical Service by assuming that a Government institution necessarily led to stagnation, delay, procrastination, the destruction of freedom, hidebound conditions and the destruction of originality in scientific work. What was the result, as tested by the appreciation of the scientific world? There were more than three times as many chemists employed by the Government in India as there were geologists;

but outside the Agricultural Department, the published work of the chemists in India was practically negligible beside the 150 volumes of valuable papers which had been issued by the Geological Survey. The small body of Geological Survey officers in India were seldom without a sprinkling of Fellows of the Royal Society among them; but so far as he knew, in the whole history of India only one chemist had to that extent been recognised by his fellow workers. Sir Prafulla Ray was afraid that chemists would be attracted from the Government service by manufacturing firms, and that consequently the service would become an insoluble residue of the least efficient members. Prof. Thorpe had already referred to, and to some extent had removed the impression caused by, that argument. There was one other feature to which he might have called attention. If the men in the Chemical Service were attracted to firms, it would only be as the result of the success of the service itself in developing the conditions which facilitated commercial success. Nothing could possibly be better for India. He wished he were optimistic enough to predict in the future the appreciable degeneration and final destruction of the Chemical Service in a way so eminently satisfactory. The Chemical Service would have done its duty to the Indian taxpayer if it proved in that way that it was no longer wanted. It would not be easy, he was afraid, to demonstrate the truth of his conclusion, but it would be very easy indeed to demonstrate the soundness of Sir Prafulla Ray's views, by refusing to establish the service at all. There was no doubt, that without it there would be no temptation for any chemist to leave the Government service. There would be no employment for him outside the Government service. But it was better, again, to judge by experience than merely to predict from imagination. What had happened to the officers of the Geological Survey? Their work had been conducted in India during a time which had been attended by a very successful mining development. He could not recollect more than two officers in the whole history of the Geological Survey who had given up their position, their prestige and their prospects of promotion in the service in order to accept improved immediate emoluments from a mining company, and those two men, he thought, might fairly be described as not entirely the best two in the service, nor did he think it would be unfair either to them or to the Department to say that their departure had not lowered the average quality of the residue. The reason was perfectly simple. An officer who belonged to a service of that sort knew quite well that he was well off, and he was not going to give up a service of which he was proud unless he was paid at rates which commercial firms were not likely to offer except under conditions of success, which could be looked forward to without any fear.

There was one other feature to which Prof. Thorpe had referred but had not summarised in a way which he thought might help one to value such a service, and that was the value of a systematic survey of raw materials. It was not research work on purely chemical problems or chemical processes which would occupy the service in its early days so much as a mere survey of information regarding the raw materials which India possessed in abundance. That survey could not be done systematically by any individual or any firm. It was the duty of Government. It would not be done, either, by any Local Government. The strong desire which was now being shown in India for Provincial control was proceeding without discriminating between two totally different functions of Government officials. There was the executive function of an official, for which decentralisation to the very full should be encouraged and allowed; and there was the advisory function, which required the very highest form of specialisation, and, therefore, could only be accomplished by co-operation and a central organisation of a kind which would enable the country to employ the very best form of specialist. The scientific officer's work in research and in advice was almost entirely of the second class—the advisory class, where it was far more important to get the opinion of a specialist than it was to act quickly and promptly. For executive work it was necessary to act promptly on the spot with whatever officer one had—not necessarily the best. For advisory work, deliberation, in order to obtain advice from the specialist, was absolutely necessary. Provincialisation and de-centralisation were valuable so long as there was a definite discrimination between those two utterly distinct functions of Government officials.

PROFESSOR HENRY E. ARMSTRONG, F.R.S., said the Chairman had implied that little, if anything, had been done in India in chemistry, although much had been done in geology; perhaps that was scarcely a fair statement, as agriculture had been well cared for over a considerable period. He thought himself that the subject of a scientific service needed discussion mainly from the agricultural point of view. It was not a question, at present, of laying down the conditions of a Service, so much as of securing some understanding throughout India of the importance of the aid which could be rendered to the country through systematic scientific inquiry. As was known, he had blue'd if not burned his fingers over indigo, and the experience he had had in that connexion was not a heartening one. A few years ago they were on the way to securing the rehabilitation of the indigo industry in India and of meeting foreign, especially German competition; but the Government and the India Office had elected to "throw up the sponge" and in a brief period the Germans had regained the position they had before the war. If the Government could not understand a simple proposition such as indigo presented, he failed to see how the much more difficult problem of a complete chemical service was to be worked out. He had noticed that Sir Alfred Mond, on his return recently from India, had spoken in very clear terms of the great need of agricultural development in India, in order that there might be an increased output of food crops for the people. The indigo work had been directly contributory to that end. He thought that, in the main, the scientific work should be done more particularly with the object of improving the agricultural conditions in India. He agreed, however, with the Chairman that there ought to be a complete scientific survey of Indian resources on the chemical side. The author had argued that "there is no reason why the recruitment of the suggested service should not be wholly Indian in the near future." That was a question which should be very fully discussed. So far as he personally could see, the mentality of the Eastern nations was not such as to make them equal to the Westerns as experimental workers. His feeling was, however, that a real beginning should be made somewhere and that some one person should be got to take charge who had enthusiasm and the necessary genius for the work—that was the difficulty, to get men of the necessary mental ability for work such as was required. We were suffering already from want of men of ability in this country. It had been hoped that, at the end of the War, instead of men of intelligence mostly going to the Bar and to the professions, more would devote themselves to science; unfortunately, the tendency had been the other way. Unless men could be attracted to science, progress would not be such as was hoped for. Everything depended on getting hold of leaders. There were Research Institutes, in a large number of places, in various countries; on the whole, however, the results were not satisfactory, except in the very few cases in which a genius controlled the work. What most concerned him, at the present time, was the fact that when he talked to young men about undertaking work in India, he found that they almost all showed none of the courage which the young men of the past had shown in going abroad, in putting their backs against the wall and succeeding by their determination; they all asked for an assured future. He was afraid that the non-existence of a spirit of enterprise in the young men of to-day stood very much in the way of the development of any such Service as Professor Thorpe contemplated.

Prof. W. A. Bone, D.Sc., Ph.D., F.R.S., said Prof. Thorpe had already disarmed a good deal of possible criticism by saying that the scheme set forth in the paper was one devised for Indian conditions at the present time, and not one which he would recommend for this country. Personally he had not been to India, and knew it only in a very general way. Prof. Thorpe had been there, and had seen the present state of chemical science in India in teaching and research, and he was quite willing to take Prof. Thorpe's recommendations as emanating from a very good judge of what ought to be done under the given conditions. He entirely agreed with Prof. Armstrong that the good which would be got out of any scheme of such a nature as that indicated would depend upon whether the right man could be got to start it. A man of the right type of genius was necessary, and he was not always to be found. It was much easier to draw up a scheme of the kind set out in the paper than to find the men who were capable of carrying it out. He thought the comparative failure of some of the research institutions which had been started in this country in recent years was due to the fact that that important consideration had not been sufficiently appreciated. By what means could men of the right qualifications be induced to go to India (that was, if they could be found), and start such a scheme? That, it seemed to him, was a point which Prof. Thorpe might usefully elaborate later in an addendum to the paper. Personally, he had difficulty in seeing where, at the present time, a sufficient number of the right type of men were to be found to carry out so comprehensive a scheme as that indicated by Prof. Thorpe. No doubt the scheme would be started on a smaller scale than that set out in the paper, and he agreed with the Chairman that initially one of the first things to do would be to survey the natural resources of India from the chemical standpoint.

Prof. J. W. Hinchley, A.R.S.M., F.I.C., said he was interested in the subject of a chemical service, not for India alone, but because he thought such a scheme was a step in the right direction. He only wished that some definitely correlated scheme of an adequate chemical service could be developed for this country, to do away with the present disjointed arrangement that existed. If such a thing could be brought about, the profession of chemist would be considerably improved. He would like to say something with reference to the paper, but it was quite possible that since his experience had not been gained in India, it might not be of special application to the problem set forth by Prof. Thorpe. He had been very interested in its solution, but there were some singular inconsistencies. He knew they were not real but only imaginary. For example, he would say: "Carry out this research, but for God's sake, do not let it be worth anything, because if you do you are going to demoralise the research worker." The filthy lucre point of view was one that had to be faced. Unless the research work increased material prosperity, no country would subsidise it. Prof. Thorpe had described the training of the chemists that he would propose for dealing with the problem of India, and had stated that chemical engineers were engineers masquerading as chemists or chemists pretending to be engineers, and then proceeded to describe his process of producing chemists pretending to be engineers. Personally, he would like to say that the reason why there were practically no satisfactory chemical engineers in existence was that in this country, at any rate, the educational institutions did not give them facilities. When he himself had been a student and had wished to become a chemical engineer, he had taken metallurgy in his third year for his Associateship, because it was a specialised branch of chemical engineering which had of necessity been developed first. A metallurgist might be an applied chemist or he might be a chemical engineer. At any rate, metallurgy was one of the earliest examples of the development of chemical engineering, and he did not think any metallurgist would consent to be called an engineer masquerading as a chemist or a chemist masquerading an an engineer.

With regard to the training of men who wished to take their place in industry as organisers and managers of industry, he was certain that the right man to fill such positions was the man who had a chance to be trained, and who had the inclination that way, both as an engineer and as a chemist during his scholastic career, and in that respect he would like to say that one could not aim at producing a complete engineer, or a complete chemist. He would like to find the chemist who pretended to a complete knowledge of chemistry. He was certain there was no engineer who claimed a complete knowledge of engineering. With regard to chemical engineering, the heart-breaking experience of the War with regard to plants* put up by the co-operation of chemists and engineers ought to be enough to convince any man who came in contact with them of the necessity of training men who went into industry after a training both in engineering and in chemistry.

The Institution of Chemical Engineers had been recently formed by a number of men who had seen the necessities of the situation. It had first been projected by Lord Moulton, who, if he had lived, would have been the first President of the Institution. It was now drafting a scheme to put before the educational authorities with regard to the training adequate for the practice of chemical engineering. He was inclined to think that such a scheme would be just as valuable in India as it would be at home. He was very glad that Prof. Thorpe's conversion to the chemical engineer was taking place on the usual lines. He had come across gentlemen of the same type who had been just as inclined towards chemical engineering, but who had gradually been converted in practically the same way. He congratulated Prof. Thorpe on his scheme, and he hoped that something would come of it.

Sir Alfred Chatterton, C.I.E., F.C.G.I., said, that during the last twenty years a considerable number of Indian trained chemists had been working under him at problems connected with the development of industries in the South of India, and he desired to pay a small tribute to the very useful work which some of these men had done. He gathered from the paper that Prof. Thorpe had not been favourably impressed with the work going on in the Indian Institute of Science, at the time of his visit, and that he regarded the obviously commercial aspect of some of the work as opposed to the aims and objects of the founder. On this point he (the speaker) would like to quote from a letter he had received from Sir William Ramsay, in 1901, just after his visit to India to advise Mr. Tata, in which it was definitely stated that the object of the proposed Institute was "to create and develop chemico-engineering industries all over India." No doubt in the lengthy discussions which preceded the actual foundation of the Institute, attempts had been made to modify this clearly defined idea, but it had persistently made its influence felt all through the deliberations of the Council which was responsible for the administration of the Institute. It must not be forgotten that the Institute of Science was the pioneer of industrial scientific research in India and that naturally, in the absence of experience, mistakes had been made and that the Institute as it was working to-day was the product of evolutionary processes of a very strenuous character. He desired to asociate himself with the anticipations of Prof. Thorpe in regard to the future, but he also thought that the very valuable work done by Dr. Travers, the first Director of the Institute, and some of his colleagues should not be lost sight of. In the course of twelve years' work at the Institute, it had furnished concrete illustrations of the various problems that would have to be tackled if chemical science was to make rapid progress in India, and in that respect at any rate the ground had been cleared for the Committee over which Prof. Thorpe had presided. Apart from the training of students, who came from all parts of India, the resources of the Institute had been mainly utilised by the Governments of Madras, Mysore and Hyderabad. Very valuable assistance had been rendered in the solution of industrial problems arising out of the war. As Director of Industries successively in Madras and Mysore, he had received much help from the Institute in respect to the work on which he was personally engaged, whilst as a Member of the Council he was in a position to testify that purely scientific research work had been by no means neglected.

Dr. J. A. Voelcker, in proposing a vote of thanks to Prof. Thorpe for his carefully prepared paper, said the problem dealt with was no easy one. Prof. Thorpe had weighed all the considerations in the case, not merely on abstract principles, but with special reference to the particular conditions of India itself—a point which many people were apt to forget. The Report of the Indian Industrial Commission practically summed itself up in the advocacy of the formation of a chemical service for India. He was sure that all who had to do with chemical matters, whether from an agricultural or other point of view, would agree that if a man was to reach the highest point in any branch of applied science, he must have had the ground-work at the outset, and he must also have had a training in research methods. Without some such Service as Prof. Thorpe had indicated, progress would be limited; but that it had been of quite such a limited nature as had been stated was, to his mind, somewhat doubtful. Certainly in the field of agriculture enormous advances had been made—although he did not say that the men engaged therein would not have been very much better if they had gone through some such training as had been indicated. His mind was taken back to 34 years ago, when he was in India. At that time there was not an agricultural chemist in the country, and there were only one or two experimental stations, which did little more than grow seed and test different varieties of plants. At the present day there was an agricultural chemist in every province, and there were 160 experimental stations. In addition there were a great number of workers in agricultural science on the purely chemical side. It was with very great satisfaction that he could look back to-day and remember that within two years of his return home the first agricultural chemist had been sent out, namely, Dr. Leather, and his assistant, Mr. Collins. These gentlemen had been followed by Dr. Mann, who had done splendid work in the tea districts, and who had really put the whole industry on a chemical basis. Other men had followed since in the indigo and other industries.

He desired to put one point of very great importance to the author of the paper for his consideration. Was it likely that the Indian would develop in the line of original research? Would there be such a school as Prof. Thorpe had indicated, which would be recruited from India itself, and which would be able to dispense with the services of scientists from this country? He had put that question to those who had worked among the Indians, but he could not say that he had as yet any really satisfactory answer. Every one knew how capable the Indian was. Certainly he could not be "floored" in any examination; but the point was would he be able to take up research on his own account? There had been, and always would be, certain brilliant exceptions; but it seemed to him that the time was still distant yet when matters of research could be handed over entirely to the Indian himself.

Sir Robert Robertson, K.B.E., D.Sc., F.R.S., said it had been borne upon him during his stay in India that everything of importance for the chemical industry of explosives had been brought from a great distance. Ships had brought sodium nitrate from Chili, acetone from Canada, sulphur from Sicily, and glycerine and cotton from England. Those commodities had been worked up under the charge of Englishmen into cordite. Since then certain advances had been made in regard to Indian production. The importation of cotton waste had given place to the manufacture of it in the mills in Bombay; and there were projects for the production of nitrates in the Ghats near that city. There were, therefore, evidences of progress, but at the same time there was an enormous field for development. He had also been struck with the difficulties which appeared to arise in regard to the exploitation of any particular Indian product. A product which would seem to be fairly easily prepared presented insuperable difficulties. In many cases the technique was known, but there were difficulties of transport, isolation, want of workers and so on. He agreed with Prof. Thorpe with regard to the necessity for seeing that men were trained in methods of research. It was after that that the difficulties seemed to him to become very great indeed, because they called into play the need for a class of man not plentiful even in this country—he referred to that class of man who had been thoroughly trained in physical chemistry, and who had in addition some knowledge of the treatment of constructive affairs. Such a class of man was in existence in Germany and played an important part in the exploitation of the German chemical industries. It would be some considerable time, he was afraid, before there were large numbers of such men in this country, and unless the Indian authorities made it very well worth the while of those men to go to India, such a scheme as that outlined by Prof. Thorpe would, he thought, come to a standstill.

The Chairman, in calling upon Prof. Thorpe to reply, said he would like to quote from memory the substance of one sentence in the Report of the Commission. In order to justify their proposal for an organised service for Chemistry and for other sciences in India, they quoted as an example the great results which had accrued from the good work done since the Government took the wise step in 1905 of founding a service for Scientific Agriculture.

Prof. Thorpe, in reply, said the question had been asked whether, in his opinion, it was possible for the Indian Universities to supply and recruit the service proposed in the paper. He thought it was. His experience was a limited one, between 20 and 30 Indian students having passed through his hands, but he thought there was no doubt that within a reasonable time, if the research schools developed, there was no reason why the service should not be self-contained from the Indian point of view. He had qualified his remark in the paper by saying that for some considerable period of time, doubtless, some home training in research would be essential for the men who would be capable of being recruited in the service.

With regard to chemical engineers, he regarded himself as a chemical engineer in the sense that he had been originally trained as an engineer and had ultimately become a chemist; but he did not think one could produce in the same man a good engineer and a good chemist. He did not know what Prof. Hinchley thought.

Prof. Hinchley said he was certain that one could.

Prof. Thorpe said that such a man would be almost as high as the angels. He was referring, of course, to a reasonable period of time. He dared say such a man could be produced if he was given ten years' training.

Prof. Hinchley said he thought such a man could be produced in a much shorter time if he was given facilities.

Prof. Thorpe said that if any remarks he had made had given any one the impression that he was

not fully conscious of the valuable work which had been done by the Institute of Science at Bangalore, he would desire that that impression should be removed at once, because the work done by that Institute was work of considerable importance. His point had been that the two things could not be combined in the same institution; one could not train men in the principles of research in the same institution in which one carried out organised commercial research such as he had suggested.

The meeting then terminated.

LA VIE INDUSTRIELLE EN FRANCE.

Les Travaux d'Agrandissement du Port du Havre.

Le port du Havre, point de départ principal de la navigation transatlantique française, a été l'objet, depuis une trentaine d'années, de grands travaux d'extension et d'amélioration. Après la création et l'aménagement de plusieurs bassins, on a décidé, par une loi du 11 février, 1909, la création d'un vaste bassin de marée conquis sur l'estuaire de la Seine, et précédé d'un nouvel avant-port entouré d'une digue. Dans ce bassin est prévu un nouveau quai de marée de 1,000 mètres de longueur, pour grands transatlantiques, et une forme de radoub de 312 mètres (1,023 ft.) de longueur.

Les travaux, interrompus pendant la guerre, ont été repris depuis, et les parties essentielles en sont achevées. Les digues en maçonnerie formant l'enceinte du bassin sont achevées, le quai de marée est en service sur la plus grande partie sa longueur, et la forme de radoub sera prochainement terminée.

Les digues limitant le bassin ont environ 4,000 mètres (4,375 yards) de longueur. Elles ont une hauteur totale d'environ 14 mètres et se composent d'enrochements de 3 grosseurs successives, surmontés de deux assises de blocs de béton, les premiers de 80 tonnes et les autres de 60 tonnes. Au-dessus se trouve un mur en maçonnerie.

Le quai de marée, destiné à l'accostage des grands transatlantiques, est terminé sur la moitié de sa longueur, sous la forme d'un mur plein. C'est un quai omnibus, permettant à marée basse l'accostage de navires de 12 mètres de tirant d'eau. Il a été fondé sur caissons perdus, foncés au moyen de l'air comprimé.

La seconde partie du quai de marée, dont la construction vient d'être entreprise, sera exécutée d'une façon à la fois plus hardie et plus économique. Ce quai sera porté sur des voûtes reposant sur de piliers espacés de 25 mètres (82 ft.) d'axe en axe, la hauteur totale étant de 29 m 50 (97 ft.) depuis la base de la fondation jusqu'au niveau du quai. Les piliers et les voûtes sont entièrement en béton, coulé dans des moules métalliques. Les pierres employées pour ce béton sont des galets de 2 à 10 centimètres (1 à 4 inches). Chaque pile est fondée sur un caisson métallique.

La forme de radoub est l'ouvrage le plus remarquable du port. Elle a 312 mètres de longueur (1,024 ft.) et 38 mètres (124 ft. 8 inches) de largeur. Elle vient donc immédiatement après celle de Liverpool (1,050 ft.) au point de vue de la longueur, mais celle-ci n'a que 120 ft. de largeur. On a d'ailleurs prévu son allongement de 50 mètres (164 ft.). Il est à noter qu'on achève, dans le port de Toulon (Méditerranée), une forme de 422 mètres (1,384 ft. 6 in.) de longueur.

Le procédé de construction employé pour l'établissement de la forme de radoub du Havre mérite d'être signalé. On a construit un immense caisson en acier, de 345 mètres (1,132 ft.) de longueur et 60 mètres (197 ft.) de largeur, dans une fouille protégée par des batardeaux. Une fois le caisson achevé et raidi par une certaine masse de béton, on a admis l'eau dans la fouille à marée haute, et on a amené par flottage la structure jusqu'à sa position définitive. On a continué le bétonnage pour noyer toute la charpente du caisson dans du béton, puis on l'a échoué à la profondeur prévue, après avoir déblayé le fond de la fouille au moyen d'injections d'air comprimé. Le fond et les côtés de la forme sont constitués, à l'intérieur du caisson, par d'épais revêtements en maçonnerie, d'une dizaine de mètres d'épaisseur totale.

La forme de radoub pourra servir, alternativement, de cale sèche et de bassin à flot. Elle est fermée au moyen d'un bateau-porte et d'une paire de portes busquées. Le bateau-porte a 40 mètres (131 ft.) de longueur, 8 m 50 (28 ft.) de largeur et 18 mètres (59 ft.) de hauteur.

On aura ainsi une idée de l'importance des travaux en voie d'achèvement au port du Havre par la masse de maçonnerie mise en œuvre; cette masse atteint 653,000 mètres cubes (854,000 cubic yards), en béton et maçonnerie, et l'entreprise a occupé jusqu'à 2,300 hommes.

L'Auto-Pompe d'Incendie Somua-Drouville.

Les Sapeurs-pompiers de Paris viennent d'adopter, pour renforcer leur matériel d'incendie, un nouveau modèle d'auto-pompe très puissant, construite par la Société Somua, et dont la pompe est du système Drouville.

Les ingénieurs qui ont étudié cet engin ont voulu fournir aux pompiers les moyens de combattre les incendies uniquement au moyen des réserves d'eau naturelles qui peuvent se trouver à une notable distance du lieu du sinistre: d'où la nécessité d'une pompe puissante, possédant un grand rayon d'action et, par suite, une vitesse élevée pour se rendre dans le minimum de temps sur le lieu de l'incendie.

En conséquence, le personnel qu'elle transporte doit être protégé efficacement, pendant ces longs trajets, contre les intempéries: sinon, par les temps froids ou pluvieux, les hommes se trouveraient dans de mauvaises conditions physiques au moment d'entrer en action et, après s'être dépensés dans la lutte contre le feu, ils seraient, pendant le retour, exposés à contracter de graves refroidissements: de là l'emploi d'une carrosserie fermée, à 8 places.

Le moteur à essence, de 80-90 h.p., sert successivement à la propulsion de la voiture et à la commande de la pompe. Celle-ci aspire par deux tubulures de 0 m 15 (6 in.) et refoule par six tubulures de 0 m 10 (4 in.) de diamètre.

Toutes les manœuvres relatives à la pompe sont faites d'un poste arrière, qui comprend les commandes suivantes: le levier d'embrayage, le levier de changement de vitesse, la commande, des gaz du moteur, les appareils de contrôle du débit, etc.

Cette pompe peut débiter environ 300 m. cubes par heure (66,000 gallons), à la pression de 5 kilogr. par cent. carré (70 lbs. per sq. inch), et 135 m. cubes (29,500 gallons), à la pression de 12 kilogrammes (171 lbs. per sq. inch).

LE SALON DE LA MACHINE AGRICOLE À PARIS, ET LES ESSAIS DE TRACTEURS AGRICOLES À GAZOGÈNES, À ESSONNES.

Paris est toujours le siège des plus importantes manifestations relatives à l'agriculture et aux industries qui s'y rattachent. Plusieurs Expositions de ce genre y ont eu lieu cet hiver, notamment le Salon de la Machine Agricole, organisé par l'initiative privée avec l'appui du Ministère de l'Agriculture. Il a eu lieu au Grand Palais des Champs-Elysées, et a compté 475 exposants et 80,000 visiteurs payants, ce qui est un record par rapport aux années précédentes.

Parmi les machines françaises pour la préparation des terres, on remarquait le tracteur Citroën à chenilles souples Kégresse, du type bien connu qui a traversé le Sahara, ainsi que le tracteur Bauche, de 10 h.p., utilisable, soit comme tracteur véritable, soit comme charrue automobile. Citons également le treuil Joya, des Etablissements Agricultural, pour le labourage suivant le système roundabout, avec 2 câbles et 2 poulies de renvoi.

De sérieux efforts ont été faits pour adapter les moteurs à la marche au gas oil, ou, de préférence, au "gaz des forêts," c'est-à-dire au gaz pauvre produit sur place dans un gazogène portatif, au moyen de bois et de charbon de bois.

Quatre gazogènes de ce genre ont été essayés officiellement à Essonnes, près de Corbeil (Seine-et-Oise): ce sont les marques Etia, Vierzon, Lion et Autogaz, construites par des firmes françaises. En outre les Usines Renault, de Billancourt, ont également créé un gazogène qui n'a pas été essayé à ce moment, mais qui a été exposé au Salon, et qui comprend un épurateur de gaz très complet. Dans la pratique, il est nécessaire de faire démarrer le moteur à l'essence, pour faciliter la mise en route.

On attache, en France, beaucoup d'intérêt à cette question, car il se perd chaque année quelque 2 millions de tonnes de menus bois et déchets qui pourraient donner 500,000 tonnes de charbon de bois, utilisables dans les gazogènes fixes ou sur des automobiles à gazogènes, camions ou tracteurs agricoles.

Citons encore, comme machines intéressantes ayant figuré au Salon de Paris, les charrues brabants doubles des Etablissements Bajac, Huard, Savary, les treuils électriques de labourage de la Société générale agricole, les arracheuses de pommes de terre Mélichar, les arracheurs-décolleteurs de betteraves Degrémont, les matériels de vinification Mabille, Simon, Marmonier, etc.

TRADE OF CHINESE TURKESTAN WITH INDIA.

The annual report by H. M. Consul-General at Kashgar on the trade of Chinese Turkestan in 1922-23 draws attention to the lack of foresight and enterprise displayed by traders in regard to fostering and stimulating their markets. Instead, they have been inclined merely to import each year the commodities which fetched the best prices the year before, regardless of whether the market could stand it or not. This tendency has been the more regrettable in that the tremendous difficulty of the route via Ladakh and the limited amount of transport available render it particularly important to study the Hsinkiang market carefully and only import commodities which are both carriable with a minimum of deterioration and certain of a relatively unlimited market. The difficulties and dangers of the Karakoram route, are well known; suffice it to say that no other trade route in existence crosses such high passes or runs for so many weeks across mighty glaciers, through precipitous gorges and along breakneck ledges among some of the highest mountains in the world. The total number of ponies and camels plying on the route is estimated at 2,000; even if the carrying trade were in a healthy state this would not be nearly enough; as it is, however, most of the carriers are insolvent and entirely in the hands of the Hindus. The latter, shortsightedly, lend the carriers money on unfavourable terms and exact repayment in the shape of retransport of goods; the carriers who must get cash from somewhere to feed their animals, accept two or three times the amount of goods their ponies can carry and take it along the road in instalments, on what is known as the "dubko" system. This causes them to fail in carrying out their contracts within the specified time, whereupon they become liable for damages to the Hindus and thus still deeper in debt to the latter. The effect on the carrying trade, and therefore on the trade in commodities, is very bad, while certain Hindus profit individually by getting their consignments carried by their debtors at cheap rates, the carriers' ponies die like flies on the road from overloading and under-feeding, consignments are frequently left for months by the roadside, and the number of ponies available for the increasing trade steadily diminishes.

It would be a pity if an unrivalled opportunity for capturing the Hsinkiang market for some years to come were lost owing to disorganisation of the carrying trade on the main Indo-Central Asian route. Just before the Russian revolution the Tsarist Government was energetically developing the trade between Ferghana and Southern Hsin-

kiang, and bade fair to eliminate the Indian merchants altogether. With their railhead at Osh only eight days march from Kashgar and with only one pass to cross, the Russian traders had an enormous advantage over their Indian rivals, and this advantage was further increased by the establishment at Kashgar of a branch of the (State aided) Russo-Asiatic Bank. Now, however, all is changed; nothing comes from Russia but small driblets of Andijan silk and velvet from Tashkend; industry, trade and agriculture in Transcaspia are alike completely disorganized, to an extent which may be gauged from the fact that whereas before the Revolution Ferghana exported a quarter of a million tons of cotton to European Russia, now it has to import from Kashgaria what little cotton it can afford to pay for. As the trade with China Proper is on a small scale and is chiefly confined to commodities used by the Chinese, Kashgaria is obliged to depend on India for many quasi-necessaries such as cotton piece-goods, dyes, tea, sugar, etc., which formerly came from Russia. By stimulating the export trade of Hsinkiang, which is capable of considerable expansion, a much greater volume of imports could be paid for by exports than at present. Moreover, large profits are to be made by re-export of the above-mentioned commodities to Russian Turkestan which can still pay in gold, furs and jewellery for a limited quantity of such imports. Mention may be made of the route via Tashkurghan, the Baroghil Pass and Chitral, which during the last two or three years has been used to an increasing extent as an alternative to the Leh route by Indian traders.

ECONOMIC CONDITION OF HAYTI.

In his recent report on the economic and financial conditions of Hayti H. M. Consul and Chargé d'Affaires at Port-au-Prince states that Hayti stands to day upon the threshold of a new economic phase in its history. How far this will prove to be a phase of progress and prosperity will depend largely upon the realisation of the objects of the Haytian-American Convention of 1915. The old Hayti with its frequent revolutions has been replaced by a new Hayti where security of life and property is assured by a well-organised and disciplined gendarmerie. The stabilizing of Haytian currency on a gold basis in a fixed relation to the American dollar has banished currency speculation and inflation with their attendant ills, and has opened the way for legitimate commerce. The inhabitants are now free to devote themselves to agriculture and to develop and profit by their country's undoubted natural resources. It is generally agreed, however, that no great development is possible without irrigation work and improvements in the means of transport. This requires capital, and as there is no capital available in Hayti, it must be obtained from abroad, either by means of a foreign loan or foreign investment. If therefore Hayti desires development, it has no other choice but to encourage foreign co-operation by guaranteeing to intending foreign investors equal opportunities with its citizens before the law and legal facilities for the ownership of land for *bona fide* agricultural, industrial, and commercial enterprises.

GENERAL NOTES.

Early Chinese Sculpture.—The Victoria and Albert Museum has acquired a magnificent life-size Chinese statue in dark grey limestone. The figure represents the Buddha Amida seated cross-legged. Behind the head is a large circular halo, decorated with elaborate floral designs of a type derived from Indian Gupta sculpture, retaining considerable traces of colour on the surface of the stone. The statue, which is a characteristic example of the great Buddhist art of the T'ang dynasty (618-906 A.D.), is probably the finest piece of Chinese stone sculpture that has yet reached this country. It is temporarily exhibited on the staircase leading to Room 62, just to the right of the main entrance.

Industrial Disputes.—From a statement made in Parliament on behalf of the Ministry of Labour it appears that the working days lost through industrial disputes in Great Britain and Northern Ireland in 1919, 1920, 1921, 1922, and 1923 numbered, approximately, 35 millions, 26½ millions, 86 millions, 20 millions, and 10¾ millions, respectively. For the months of January and February, 1924, the corresponding figure was over 1,300,000. The foregoing figures relate only to days lost at the establishments where the disputes occurred, and no figures are available as to days lost at other establishments. Disputes involving less than 10 workpeople, and those lasting less than one day are not included in these figures, unless the aggregate duration (*i.e.*, the number of workpeople involved multiplied by the number of working days) exceeds 100 days.

MEETINGS OF THE SOCIETY.

Indian Section.

Monday June 30, at 4.30 o'clock.—J. C. French, I.C.S. "The Art of the Pāl Empire in Bengal." The Right Hon. the Earl of Ronaldshay, G.C.S.I., G.C.I.E., will preside.

Dominions and Colonies Section.

Monday, June 16, at 4.30 o'clock.—C. V. Corless, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada." Sir Richard Redmayne, K.C.B., M.Sc., M.Inst.C.E., M.I.M.E., M.I.M.M., F.G.S., Chairman Governor, Imperial Resources Bureau, will preside.

Journal of the Royal Society of Arts.

No. 3,734. VOL. LXXII.

FRIDAY, JUNE 13, 1924.

16 JUL 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2).

NOTICES.

NEXT WEEK.

MONDAY, 16th JUNE, at 4.30 p.m. (Dominions and Colonies Section.) C. V. CORLESS, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada." SIR RICHARD REDMAYNE, K.C.B., M.Sc., M.Inst.C.E., M.I.M.E., M.I.M.M., F.G.S., Chairman-Governor of the Imperial Resources Bureau, will preside.

DOMINIONS AND COLONIES SECTION.

MONDAY, 2nd JUNE, 1924. RT. HON. VISCOUNT MILNER, K.G., G.C.B., G.C.M.G., in the Chair.

A paper on "The Mandate System and the British Mandates," was read by The Rt. Hon. SIR FREDERICK LUGARD, British Member of the Permanent Mandates Commission, League of Nations.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

EXTRA MEETING.

MONDAY, MAY 5TH, 1924.

SIR HERBERT JACKSON, K.B.E., F.R.S., in the Chair.

The paper read was:—

PHOTOGRAPHY IN SCIENCE, INDUSTRY AND MEDICINE.

By T. THORNE BAKER, F.R.P.S.

(Director of Research, Imperial Dry Plate Co. Ltd., Research Laboratories).

The attempts of early experimenters to "fix" the ephemeral image of the camera obscura were undoubtedly actuated by motives of art; the possibility of such an accomplishment having vast scientific applications was certainly never foreseen in those early days, and I doubt if to-day more than an insignificant fraction of the general public realizes how this great science is wrapt up with their everyday life.

Photography may be said to have passed through four great stages. The first embraced the hopes and the theories and attempts of men to imprison the image of the camera obscura, from the time of its description by Leonardo da Vinci to the early work of Niépce. The silhouette and positive impressions on metals represented a second stage, which might be said to have continued in its gradual development throughout the early days of the wet plate. The dry plate, due to the historic work of Dr. Maddox and others of that time, introduced a third phase which saw slow, but astonishing development. The fourth stage, in which we find it to-day, began when trained scientific men began to concentrate their attention and research upon not only the understanding of the photographic processes in use, but upon their possible applications to various branches of commercial and scientific work. In this stage there was, of course, the discovery of the X-rays in 1896, which has been responsible for photography playing an enormous part in medical work, and more recently in the solution of some of the most vital problems of physical chemistry.

It would be quite impossible within the limits of a single lecture to give any detailed account of the very large number of industries which at the present time are either directly or indirectly dependent on photography, but I hope to be able to present a few selected instances of general interest in which this great science is playing a part.

We might, with advantage, devote a few moments to consider what, in the art itself, has contributed to its present high state of efficiency. We know for example, that photographs can be obtained with a ten-millionth part of a second's exposure; that the aeroplane surveyor can take photographs through mist of landscapes almost invisible to the eye; that a microbe, a twenty-five thousandth of an inch long can be magnified two hundred million times in area and that its photograph produced in ultra-violet light will reveal a remarkable amount of that exquisite structure on Nature's part that the eye of man will never see unaided. We can make sensitive plates or films which vary in speed by a thousand times, and turn them out with surprising uniformity and mechanical perfection.

In other words, the plate chemist has learnt the secret of the sensitiveness to light of silver bromide; he can produce an emulsion in gelatin of this unique substance which shall have a predetermined size of grain, of contrast giving power and rapidity. He can make it sensitive to all the colours of the spectrum, to the invisible infra-red and ultra-violet rays, to the X-rays and shortest wave motions produced by radium.

The progress of photography has been largely due to the extension of the colour-sensitiveness of the photographic plate. The slide on the screen shows a photograph in natural colours of the spectrum of arc light produced by the diffraction grating.

In this familiar spectrum we see, roughly speaking, three regions of colour—blue, green and red. The light of those colours is caused by wave-motions in the ether which vary in wave-length from 4 ten thousandths of a millimetre to 7 ten-thousandths of a millimetre, from crest and crest as it were. Photographers dealt for years mainly with these visible colours of which only the violet and blue affect an ordinary plate, and twenty years' continual labour was devoted to making silver bromide more sensitive to the green, yellow and red rays. But let us see now in the next slide, the enormously increased range of wave-lengths with which we deal to-day; it is this extension in range with which photographic progress is so intimately associated. Here we find radiations of wave-length as short as one ten-thousandth of a millimetre only, the shortest characteristic radiations excited by X-rays in the elements, ranging through that region, recently discovered, where the X-rays themselves begin to overlap, or merge into the ultra-violet, and extending from the ultra-violet through the visible and infra-red spectrum to the waves that we know as heat, and—still further on—as "wireless." Thus the wonderful range of colour which nature has allowed the human eye to see is only a mere fraction of the vast range of wave-lengths to which the photographic plate is susceptible, which extends from less than one Ångström unit to a wave-length of at least 50,000 A.U.

The photography of the ultra-violet has proved of the utmost importance; it has perhaps even paved the way to the production of the food and power on which future generations will depend. Take as an example the production by means of light of synthetic formaldehyde and sugar, with which the names of Dr. Moore and Professor E. C. C. Baly are intimately associated. Under the stimulus of ultra-violet rays of certain wave-lengths the waste gas of the atmosphere—carbon dioxide—will react with water to give formaldehyde which is further converted into reducing sugars. The measurement of wave-lengths chosen must be done with the aid of photography, which has thus directly assisted Prof. Baly and his colleagues to probe the secret of vegetable life and to reproduce in the laboratory the actual life processes of plants. One has only to carry the work further and to produce on a commercial scale starches and sugars which on fermentation can be converted into alcohol, and the production of power from the enormous quantities of waste gases in the atmosphere becomes a thing of possibility.

There is an old story of Bunsen and Kirchhoff looking at a fire at Mannheim through an early spectroscope, in which quantities of strontium had imparted to the flames a characteristic red colour. The philosophers were made to wonder whether it might be possible to recognize a substance by the nature of the light emitted at far greater distances. As we know, spectro-photography has since those early days not only told us the nature of the constitution of the sun and of immense numbers of stars but has enabled us to calculate the velocity of celestial bodies and has opened up an inexhaustible pathway into the unknown, while spectrum analysis by photography has reached a state of extraordinary precision, and has become widely adopted in the laboratories of both research and industry.

If the light from an electric arc or spark be examined with the spectroscope, superimposed over a more or less even band of colour are bright lines, due to radiations caused by the change of orbit of the electrons revolving round the positive nuclei of the atoms. The slide on the screen shows a photograph of the electric arc, the poles of which have been brushed with a solution of lithium chloride. In modern forms of spectroscopic cameras, or spectrographs, the ultra-violet region is usually included with the visible region, and a scale of wave-lengths is photographed on each negative contiguous to the spectrum, so that the principal lines can be easily identified. Such a camera is seen in the next slide, while we next see three spark spectra, the oscillatory spark discharge taking place between electrodes of aluminium, iron and tungsten.

As a means of rapid chemical analysis by measuring the wave-lengths of the principal lines, the spectrograph is unique, especially as it indicates such excessively minute quantities. The constituents of London tap water can be identified from a single drop of the water placed on the electrodes of the spark gap, though it contains only the three thousandth part of a grain of solid matter. Minute traces of zinc in the venom of the cobra have been detected in a similar way, minute quantities of nickel in fats, traces of mercury in explosives, and so on.

A great deal of information has been obtained in the realms of organic chemistry by photographing the shape of the absorption curves of substances, particularly in the ultra-violet region. Examples of visible colour change are seen in the two next slides. These are spectrograms taken with a neutral grey wedge placed in front of the spectroscope slit—this has the effect of producing an image at any point along the spectrum corresponding to the degree of transparence of the substance under examination. Thymol blue, for instance, is ordinarily a yellow dye, the absorption curve of which is now seen ; a minute trace of alkali turns the dye indicator pink, when its colour as analysed by the spectrograph appears as seen in the lower spectrogram. The next slide shows a similar change in bromo-cresol purple.

Where the "colour" is invisible, that is to say, the absorption band is in the ultra-violet, it may be measured in various ways with the ultra-violet spectrograph. I will show one typical example made by Dr. Judd Lewis, who has already described his methods before the Society. The result of these series of exposures is to obtain data which give the shape of the absorption curve of a solution and the study of these characteristic shapes has given an immense amount of new information to the organic chemist and to the physicist.

In the case of a line spectrum, in which the relative brightness or intensity of the various lines is different, the neutral wedge has been recently used to measure photographically the comparative strength of the lines.

The effect of photographing a line spectrum through the wedge is seen here, and you will notice that the stronger lines are of greater height. This height does not depend on the brightness of the lines only, but upon the characteristics of the photographic plate used ; Professors Nicholson and Merton have done some valuable work on the intensity and distribution of spectrum lines in this way.

Another instance of the applications of spectro-photography may be seen in a series of photographs of a wireless transmitter spark ; here we see that a change in wave-length caused by tuning with inductance alters the characteristics of the spectrum in an entirely different manner from that caused by tuning with capacity. The wave-length of the wireless radiation or spark frequency is exactly the same in the case of the two lower spectrograms, yet the character of the lines is entirely different.

You will thus see that the photography of the spectrum has many fields of application. They are, indeed, so numerous that it is impossible to give more than a few indications of them in the time at our disposal.

A short account of some of the modern research work on photographic chemistry becomes necessary here to show how diverse characters of plates can be prepared to deal with the varied subjects which I shall briefly refer to presently.

The sensitive film of a photographic plate is prepared by emulsifying silver bromide in gelatin. The precipitate at first formed consists of minute crystals of silver bromide. These crystals are too small to be seen as such even at a magnification of ten or fifteen thousand diameters. They rapidly increase in size, however, when they are seen to consist chiefly of flat triangles and hexagons. We shall see in the next three slides this progress of growth. The first shows the silver bromide at an early stage ; the second at a later stage ; the third shows the grains of the fastest plates yet made.

Now the general difference between the slow plate used for photo-mechanical reproduction and the rapid plate used for recording purposes, lies in the difference in crystal dimensions. As we have seen the size and sensitivity of the grains can to-day be controlled with remarkable accuracy, so that the plate maker is able to produce—for various purposes—a wide range of plates varying a thousand times in speed, and at least ten times in density-giving power.

We can, as you know, render the plate, ordinarily sensitive to blue-violet rays alone, sensitive to various parts of the spectrum—to green, yellow, red, infra-red or ultra-violet. This is done in the case of visible colours and the infra-red by means of dyes, which make the silver salt absorb the rays required to affect the plate, and in the case of the ultra-violet and X-rays by modifying certain physical characteristics of the emulsion, which presumably has the same effect.

The next slide shows three types of plate—the ordinary one, sensitive to blue-violet, and two types of so-called panchromatic plate which are affected by rays throughout the entire visible spectrum. Photography in the extreme ultra-violet is a more difficult problem, as the gelatin vehicle used to carry the silver bromide is strongly absorbent. Plates are, however, made commercially which will record admirably up to 1,800 A.U., and much valuable work has been done with them. A great deal of attention has been devoted to plates specially sensitive to X-rays, and, as we shall see later, they have played an important part in radiographic progress.

There are other matters to be considered in scientific work. The size of grain has often to be exceedingly small in order to obtain sufficient resolving power. One of my colleagues in the Imperial Dry-Plate Research laboratory, Mr. L. F. Davidson, has recently obtained photographs of the silver bromide crystals in the actual progress of development, at a magnification of 15,000 diameters, and those have shown that, under certain conditions, the exposed crystals burst during the process of reduction, and throw off "shoots" whereby they join up with adjacent crystals and form large grains which entirely prevent the fine definition required for certain classes of work. An agglomerate grain composed of crystals which, on development, have joined up by extrusion, is seen in the slide now on the screen.

A vast amount of fresh information regarding the sensitive film, its preparation and its behaviour, has been gleaned during the past three or four years, a large proportion of which has been due to the application to photography of *itself* in the form of high-power photo-micrography. This brings us to the field of miscroscope work, in which photography to-day plays so eminent a part.

At a symposium of the Faraday Society held in September, 1920, dealing with the microscope, Mr. S. Whyte set forth in a few words some of the uses of miscroscope in engineering works; by its means inherent defects in steel are discovered; troubles arising through bad ingot pouring, faults arising in the forging or stamping of steel, and so on, are detected with its help. In fact the microscope, with its auxiliary, the camera, is to-day an essential part of the average engineering works equipment.

On the occasion of this meeting, Sir Robert Hadfield suggested that one of the objects we ought to have in view should be to obtain increased knowledge from examination at *higher* magnifications, that is to say, 5,000, 8,000 and still higher.

That was less than four years ago. A few weeks ago a photo-micrographic apparatus, designed by Mr. N. P. Chopra, was announced, which permits of magnifications of 25,000 diameters or more—over 600,000,000 times in square measure. By Mr. Chopra's courtesy I am able to show two photographs of his apparatus and one or two specimens of his high-power magnification work.

An interesting industrial use of the microscope, employed in rather a novel manner, is illustrated in the next slide. Here we see two photo-micrographs taken of thin sections of wood, which is being aged or seasoned by a new process that is giving excellent results in about 9 days against several months or even years. A long series of these photographs were taken at intervals of ten minutes, and were then printed on cinematograph film and projected as a motion picture. Projected at the rate of sixteen pictures a second, the whole nine days' process of seasoning is seen within 81 seconds. Many industrial processes are being dealt with in this way, and, as you can understand, the advantage of watching a slow chemical or physical process take place at high-speed is of the utmost value.

Opposite to such a process is the *slow* motion picture, which analyses an action too rapid for the eye to follow, so that it can be followed at leisure. Photographs are taken for this purpose at the rate of 140 a second, sometimes more, and are reproduced at the usual rate of sixteen a second. A movement which actually lasts a tenth of a second thus appears to have a duration of nearly a whole second. The application of this type of photography has been found of considerable value in certain industries, where men or women are engaged in some manual operation requiring dexterity. The output of one worker may be much lower than that of another, due to some lack of skill in manipulation. By taking a slow motion photograph of the operator at work, the reason of this lack of dexterity is usually revealed and can be made good.

Messrs. Pathé have very kindly prepared a new film of this type for me to show to-night. It is preceded by a short slow-motion picture of animals jumping; the industrial picture shows rivetters at work in a shipbuilding yard.

A good deal of work is being done on the slow-motion camera to-day. In order to take pictures at the rate of 128 a second, the actual exposure must only be 1/272nd of a second, and in the Bell and Howell ultra-rapid mechanism the weight of the moving vane or shuttle which regulates the exposure has been reduced in weight to 70 grains. A flexible shaft enables the mechanism to be driven by a handle some distance away from the camera, so that all vibration is avoided, although the peripheral speed of the main shutter is several miles a minute.

The speed of recording is very much greater than this in the case of rapid cinematography, and photographs have been secured as many as 5,000 per second for scientific research.

These photographs are of quite a different type to those which have solved certain physical problems, of which Prof. Boys' pictures of the flight of bullets and Prof. Worthington's records of the initial stages of splashes, and so on, are examples. The actual exposure given in some of these cases has been that of the spark discharge of a Leyden jar, lasting less than one millionth of a second. Prof. Boys actually reduced his exposures to the ten-millionth part of a second in photographing rifle bullets travelling at the rate of 1,000 miles an hour.

The fact that a light impact lasting one ten-millionth part of a second can so alter the sensitive grains of a photographic emulsion as to render them developable brings us to the modern ultra-rapid plate which is constantly finding more further practical applications.

The preparation of the "fastest" plates depends, to a large extent, on the purpose for which they are required. The action of light, presumably in causing an emission of electrons by photo-electric effect, can only take place when light energy is absorbed. It is thus necessary in dealing with ultra-violet light to use a silver bromide emulsion the opacity of which to ultra-violet is a maximum, but care has to be taken also that the grains of silver bromide have reached their maximum sensitivity irrespective of their selective absorption.

Plates specially sensitive to ultra-violet have recently been used for ordinary photography with a new lens I have designed, made with quartz, corrected by a component lens also transparent to ultra-violet. With such a combination it is possible to reduce the time necessary to take a photograph to one fifth of that required at present; modern plates of a speed of 600 H. & D., thus have the effect of a speed of 3,000 H. & D., and some entirely new possibilities may be opened up in this way. As an instance of what may be done in just an ordinary way I will show a snapshot taken with this lens in an ordinary room lighted merely by a couple of incandescent gas burners.

A most important commercial application of the very sensitive plate has been recently developed in aerial survey work. During the war a great deal of thought and experiment was concentrated on the problem of photography from the air, and immediately afterwards the methods that had been so successfully worked out were applied to practical peace-time purposes. Much of the map-making and survey work of the future will be done by aerial photography; it is finding extensive use in the survey of ground for road transport, and for recording the development of the land by railways, for studying the congestion of harbours and aiding the architect in factory construction. This year entirely new applications are to be made. One of these is to illustrate, for the education of children, various geographical terms which are not easy to visualize in the ordinary way, such as delta, miasma, meander and so on; no geography book could possibly give the student the admirable grasp of the significance of such terms which is given by the birdseye view of the aerial photograph. Another is to illustrate for science students the works process as it exists, and not as the present-day text-book has usually to describe it with entirely inadequate sketches and plans.

We can perhaps get a better idea of the potentialities of this branch of photography by briefly studying a few actual examples, which have been kindly lent me by Messrs. Aerofilms, Ltd., of the London Aerodrome, Hendon.

Great assistance has been given to aerial photography by the advances made in sensitizing plates for the green and red rays, which enables the use of a yellow or red colour screen in front of the lens to cut out the large amount of ultra-violet and blue rays reflected from the particles of atmospheric haze and so to secure clear definition.

Let us turn now from the recording of such extensive subjects to the more delicate, but equally important uses of photography in electrical and physical science.

As a first instance we might take the oscillograph—an electrical instrument which responds to minute currents and causes the fine wires placed in a magnetic field to become displaced, a tiny mirror attached to the wires throwing a spot of light on to a travelling photographic film, so that it can record actual wave-forms of electric currents and other vibratory systems. Another form of instrument is the Einthoven galvanometer, which we see on the screen; a silvered quartz fibre is placed in the magnetic field, and it is used as a minute shutter which stops the passage of a pencil of light directed upon a falling plate, placed in the apparatus you see here. The change of potential caused by muscular contraction is made to influence the galvanometer, and the movements due to the currents are recorded on the plate. Electrodes are placed upon the skin of the patient, three so-called "leads" being recorded, from right arm to left arm, right arm to left leg and left arm to left leg. Such a record you now see, as made with the Cambridge and Paul cardiograph. This is of the normal heart; the next slide shows a case of auricular flutter, the next a record of a dog under an anæsthetic, and in the next slide we see a cardiograph recorded in a consulting room half-a-mile away from the patient, the currents being transmitted over the ordinary telephone line. The examination of a patient by joint telegraphy and photography opens up rather an astonishing field of possibility!

The Einthoven galvanometer was used more than ten years ago to record wireless messages upon a travelling band of photographic paper. As may be imagined, the photographic recording of these electrical instruments has very numerous applications, far more than one could deal with on the present occasion.

A recent innovation in this direction is worthy of mention; it is Mr. J. H. Powell's radium capsule,* used as a very sensitive recorder where there is very little power to operate the recording mechanism; instead of using a recording pen or stylus to trace a record, a small brass capsule is fitted to the moving part, at the closed end of which is a small speck of radio-active material; at the opposite extremity a small aperture allows the radiations to fall in a parallel beam upon photographic paper.

Another instance of photographic recording is the sonometer recently devised by Professor Low, a diagram of which you now see. A pencil of light is deflected by a diaphragm which is vibrated in accordance with the sounds impinging on it, and a fine spot of light makes its record upon a moving plate or band of sensitive paper. The definition is very fine indeed, as can be gathered from the results we shall now see.

This instrument has wider applications than the analysis of vocal and musical sounds; it can be used in engineering work for such purposes as testing periodic errors in geared machinery, and has indeed been called the "stethoscope" of the engineer.

High-speed plates are, of course, essential for much astronomical and meteorological work. Through the courtesy of Mr. Dobson I am able to show two excellent records of meteors in flight, taken on extremely rapid plates which have been slightly fogged by preliminary exposure to light in order to overcome the inertia of the sensitive emulsion.

If we look at the curve connecting exposure with density in a photographic negative, we see that there is a period of exposure during which a minimum amount of light has no effect, and that for the first active period of the exposure the density obtained is insignificant. After this period, additional exposure gives rise to a more or less steady increase in density. The plate is sufficiently light-fogged just to overcome this inertia period. Then any additional light from the meteor will be added to this effect, and on development it will be recorded by useful density. Professor Lindermann and Mr. Dobson utilized this effect with marked success, and found that the star track came out clearest when the fogging could just be seen.

---

* Journal of Scientific Instruments, I, vii., 205.

To effect a measurement of the height of meteors, two similar cameras were set up 5 kilometres apart pointing to the zenith, and oriented so that the edges of the plates were parallel to the base line.

The necessity of changing the plates by hand throughout the night was avoided by means of an automatic changing device controlled by electric contacts in a lock. The camera could be opened and shut at any pre-arranged time as the wheel of the focal plane shutter was provided with two stops which engaged with the armatures of two electro-magnets.

To obtain the speed of a meteor, a revolving sector driven at a constant speed was fixed over the lens of one camera; by this means the track of a meteor is seen to be broken at regular intervals, and in this way the velocity can be measured.

The slides show two photographs of an unusually bright meteor; the track was so long that neither the beginning nor the end is on the plate. The height when it passed overhead was 83½ km., and its velocity 35½ km., per second.

A further interesting example of the uses of extreme speed plates is for the study of various industrial conditions of working, about which much more information is being demanded by those interested in industrial hygiene. I will show a couple of photographs taken under very adverse conditions of lighting, recently obtained in coal mines. Such photographs have been almost impossible to obtain until the recent advance in the speed of plates was achieved a year or two ago.

The slide now on the screen shows an example of the application of photography to radioactive phenomena. It shows the bombardment of a nucleus of an atom by an alpha particle of radium and illustrates the actual breaking off of a hydrogen atom and thus shows the transmutation of an element. It was the first successful photograph abtained of an end-on collision after 21,000 attempts.

A branch of photographic work that is attracting some attention just now is the telegraphic transmission of pictures. It is not long since you had at this Society M. Edouard Belin, the French inventor, who has devoted a great deal of time since about 1904 to this fascinating subject. He showed some remarkably good results of photographs transmitted by his apparatus and I hardly think I need enlarge on the merits of his system on this occasion. It was Professor Korn who really inaugurated commercial photo-telegraphy, in 1907, with his selenium apparatus, with which many portraits were telegraphed from both Paris and Manchester to the Daily Mirror office in London, and were published in that newspaper. This was followed subsequently with an apparatus of my own, which was in constant daily use for upwards of two years, and as far back as 1912 I showed, at the Royal Institution, an experimental picture sent by wireless with this apparatus, in the days before the modern valve had been developed.

I think a great many people must have wondered why these familiar telegraphic pictures suddenly ceased to appear. The truth is that the cost of a long distance telegraph or telephone line had proved altogether prohibitive. I hope that before very long a new system will be at work, on a really commercial scale, in which the time of transmission, by either metallic line or wireless, has been reduced to 2½ minutes; the system is entirely automatic, and for wireless work the difficult problem of synchronising the sending and receiving instruments has been entirely eliminated; I cannot unfortunately, say more about it at the moment.

An example of a telegraphed photograph is seen on the screen which was transmitted from Manchester to London on a metallic circuit.

I do not propose this evening to touch on the very important matter of general illustration. That the photographic process is involved in practically every printed illustration in the world's peridicals is well-known. There are new methods of printing which are rapidly developing—rotary lithographic, offset and rotagravure, which make it possible to produce really high-class illustrations on the cheapest of papers at a remarkable rate. It would be impossible to attempt to do justice to any one of these processes on the present occasion, but I should like to point out how much recent photographic progress has contributed to their success. A great deal of most valuable research has been carried out by Mr. A. J. Bull and his colleagues, at the Bolt Court School of Photo-engraving, and the art of half-tone engraving and photogravure has been reduced very much to an exact science instead of remaining as it was a few years ago, a matter more or less of individual skill guided by intuition and long experience.

Photo-engraving is one of the greatest and one of the most successful applications of photography, and it is one which touches every one of us to-day, as a world devoid of illustrations would render modern business impossible and would indeed be unimaginable.

We come finally to the field of X-rays, in which photography has not only developed a science that has proved of the utmost benefit to humanity, but has assisted the physicist to carry on investigations that have enabled him to reorganize and greatly to extend our knowledge and conceptions of matter. We can claim for photography that it discovered radio-activity; we can equally claim for it that it has definitely established the lines on which Nature's architecture is based.

As far as the medical side is concerned, we have only to look back to 1896 to remember the crude early radiographs that were taken, when the exposure necessary to obtain an X-ray photograph of the hand might extend to several minutes. Very rapid progress was made, and even during the South African war the extraordinary value of the X-rays was proved. It gradually became apparent that X-ray photographs would not only reveal swallowed coins, bullets and the position of fractured bones, but that muscles and tendons "showed up" as well. Then came the knowledge that by suitably choosing the penetrating power of the rays it was possible to differentiate between organs of the body of different opacity. To-day, the early signs of tuberculosis can be seen in a good radiograph of the lungs, with so much success that the miners of the Witwatersrand are examined monthly by X-ray photography, and on this examination of their lungs depends their permission to continue at work in the mines.

By taking a "meal" of some harmless, but opaque substance, such as barium sulphate or bismuth carbonate, a series of photographs taken at intervals can be obtained, showing the whole of the alimentary tract, and just recently by the injection of lipiodol, photographs have been taken showing the circulatory system of the chest and the bronchial passage with exquisite detail. A good idea of this new technique is seen in the two photographs on the screen. The first radiograph is an ordinary one, the second is of the same subject after the injection of lipiodol.

The great progress of X-ray work has been due as much to electrical progress as to advances in photographic technique, but some tribute is due to the great perfection which has been attained in the preparation of plates specially sensitive to the rays, and to the so-called intensifying screens which enable a reduction of nearly ninety-five per cent. to be made in the exposure. The effect of one of these screens is seen in the next slide; a piece of intensifying screen is laid half across the plate, and you will see how its effect is to provide far more detail for a given exposure.

These screens are of great value in taking photographs of internal organs (such as the stomach, after a barium meal) where the finest detail is not required.

Such powerful apparatus is made to-day that even where definition is of paramount importance, exposures can be made in a small fraction of a second. The slide on the screen shows a snapshot of a heart taken in the thousandth part of a second by means of an apparatus known as the "single-flash."

The immense progress in radiography made in *recent* years is very largely due to the brilliant invention of the Coolidge tube. Dr. Coolidge devised an X-ray tube in which the power and penetrating qualities of the rays can be controlled so completely that a standardisation of the beam may be attained which was conspicuously lacking in all previous apparatus.

By the courtesy of Mr. Geoffrey Pearce, of Messrs. Watson & Sons (Electro-Medical), Ltd., I am able to show a very modern portable equipment provided with what is known as a "Baby Coolidge" tube. You will see that when a local current is applied to the cathode, a small tungsten spiral on its surface becomes incandescent. This spiral throws out a stream of electrons the number of which controls the resistance of the space between the cathode and the anode. The tube is exhausted to about a thousand-millionth of an atmosphere, and its resistance is so great that no current will pass through it until the electron stream makes a passage. By varying the degree of incandescence of the filament, the resistance of the tube is lowered and a heavier current can be passed.

A great advantage of the Coolidge tube is that with it excessively soft rays can be produced, so soft indeed that the delicate structure of cherry blossom and similar objects has been radiographed, while on the other hand the rays can be made at will so highly penetrating that the new science of radio-metallography has been established. The penetration, in fact, has been found to be a function of the voltage which is applied to the tube terminals, and while with a pressure of fifty or sixty thousand volts we can penetrate the human body, with 120,000 to 200,000 volts we can photograph *through* a solid steel casting two inches in thickness.

As an example of the use of soft rays, I will show first a cheap briar pipe made of inferior wood, the holes of which have been filled with putty. This radiograph suggests to all smokers the expediency of having a pipe X-rayed before buying it!

I have one or two other examples of aluminium welds, a faulty aeroplane magneto and a casting of inferior alloy, which we will glance at briefly.

An indication of the value of this branch of radiography in industrial research may be gathered from some interesting specimens which Sir Robert Hadfield has kindly lent me to show to-night. These are radiographs taken of large carbon electrodes as used in electric furnaces. The first three show radiographs of the raw materials used—retort carbon, pitch and anthracite. The two next slides show, first, an electrode in which distinct structure is visible, and second, a graphite electrode devoid of structure yet manufactured from the same three raw materials.

We come finally to the still newer phase of X-ray photography, the analysis of crystal structure and X-ray spectrography. So much work has been published by Sir William Bragg, his son and their colleagues, on this subject, and you have so recently had an admirable lecture at this Society on crystal structure, that I need do no more than make a general reference to the subject as being yet a further application of photography to scientific research.

Under suitable conditions we can produce a spectrum of the very short wave-length radiations of X-rays, just as we produce—with the far coarser dispersing medium of the prism or diffraction grating—a spectrum of white light.

The most practical application of this work lies, perhaps, in the power of crystals to disperse the rays in the manner of a diffraction grating In any crystal the atoms and molecules are arranged according to a definite system, and the atoms of the same element are all arranged so as to occupy the points of the space lattices. The planes of atoms act as diffracting surfaces and if a very narrow beam of rays be directed upon a small tube of a crystalline substance, the diffracted rays will form lines at intervals regularly spaced according to the crystal structure, and these lines can be recorded upon a photographic plate placed behind the tube. As each line is at a distance from the centre of the plate dependent on the distance between the planes of atoms in the crystal, there is one line for every important set of planes in the crystal. Hence substances with different crystalline structure give entirely different patterns. By developing this technique new methods of chemical analysis have become possible which are likely to prove of the greatest advantage in the technical laboratory.

Sir William Bragg has very kindly lent me some examples of his recent work to show you to-night, representing the crystal structure of phthalic acid, naphthalene and other substances. Some of this work has already found practical application in the industries, and while no-one can, as yet, tell quite where it will lead, it is certain that this branch of photography has already provided an enormous amount of new knowledge.

We find the analytical uses of the X-rays applied in many directions. Thus only recently Prof. Sebelien[*] described how at the Norwegian Agricultural Institute, he had analysed by crystal structure samples of ancient bronzes, including the bronze bands from the gates of Shalmaneser II., which are now in the British Museum. Various objects belonging to the earliest dynasties were found to be of very pure copper, without any trace of tin, whereas objects from a later period were found to be real tin bronzes of normal composition.

---

[*] British Association Paper, Section H, 1923.

In conclusion, I feel that it is necessary to make something in the way of an apology to you for dealing in so brief a manner with many subjects which are deserving of the fullest study. But the main object of this lecture has been to attempt to indicate what a vast field is covered to-day by photography, and the very fact that we have had to pass so many subjects so rapidly under review is really the best testimony to the usefulness of the photographic process.

DISCUSSION.

Colonel C. N. Simpson, D.S.O., R.F.A., asked the author if barium was superior to bismuth for taking X-ray photographs.

Mr. Thorne Baker replied that bismuth was now practically obsolete, because barium was so very much cheaper, and also the effect was rather better with barium than with bismuth.

Dr. G. H. Rodman desired to congratulate the author upon having brought to their notice a very interesting description of modern photographic processes. It had been his lot for many years to be associated more or less in different directions with the use and application of the photographic plate for scientific research. The Chairman remembered, probably, as well as he himself did, the first occasion on which Mr. Campbell Swinton had made an X-ray exposure upon his own hand at the London Camera Club. That was the first exposure in which a photographic plate had been impressed by the Röntgen rays in public. That result, he was glad to say, was likely to remain on view, seeing that it was printed in a permanent process, and could be seen in the Museum of the Royal Photographic Society. On that occasion, if his memory served him rightly, it had been necessary to give an exposure of 18 to 20 minutes through an aluminium plate, with the idea of screening off certain of the rays which were not considered at that time necessary for photographic purposes. When one came to consider that an eminently more satisfactory result was obtained at the present time in as short a period as that mentioned by the lecturer, namely, something like one-thousandth of a second, by a single flash, that in itself spoke for the progress which the science of radiography had made, aided, as it had been, by the work of the photographic chemist, who had produced not only extremely rapid emulsions, but by the use of intensifying screens with which the exposure was reduced by something like 95 per cent.

The illustrations of the photography of metal surfaces which had been shown on the screen were, to his mind, some of the best work which had been exhibited. Those surfaces of metal were, in his opinion, extremely fine examples of the application of photography for the recording of metal structure.

The author might have stated that, even in the world of art, the X-ray and the photographic plate had come to the service of scientists and investigators. By means of the application of radiography, as had been shown by Prof. Heilbron, of Amsterdam, some years ago, it was possible to discriminate between a faked oil painting and one which was unfaked, and by this he meant any old picture which had had subsequently added to it a super-imposed image of modern day production. This could be readily disclosed by the X-rays which were intercepted to a much greater extent by the lead containing pigment of the original painting than was the case by the material used in the later addition. The aniline dyes and colours such as those employed at the present time had very little resist as compared with the metallic material used in the old day paintings.

The Chairman, in moving a very hearty vote of thanks to the author for his paper, said the Royal Society of Arts was to be congratulated on being able to publish in its *Journal* such a complete and informative account of the applications of photography. Mr. Thorne Baker's name was known to all in the photographic world. He had never ceased working on investigations in photography, and it was well known what a large amount of successful work he had done. He thought Mr. Thorne Baker might rightly plead that there was perhaps a little want of appreciation of the importance of photography in so many directions. It was a little to be regretted that the number of people taking an active interest in photography—he meant those interested in carrying out all the processes of photography, and not only those who were merely using the lens and exposing it—had decreased. He supposed, however, that that was inevitable, because the younger generation at the present moment was distracted; it did not know whether to leave wireless to take up photography or not; but when those two sciences were brought more closely together, and each was helping the other, then the next generation would be working at both at the same time. It was only possible to go on making great strides in researches in a subject which was of such value in its practical applications when there was in the country a flourishing industry in connection with it; and it was to be hoped that in this country we might not cease always to have a flourishing photographic industry.

One could remember many of the matters mentioned by the author—for instance, the use of dry plates for spectrum photography in the case of very feeble lines. In the old days photographers had been in the habit of slightly fogging the plate, and in the complete explanation of that effect and what was really being done lay a very important discovery.

The vote of thanks was put and carried unanimously.

Mr. Thorne Baker, in reply, said the paper had not been an easy one to write; yet he felt that the time had to come when it ought to be put on record what a very large field photographic work was covering. Photography and photographic chemistry had risen to the dignity of one of the great sciences. He remembered 30 years ago, when he had been a boy at school, that he had taken out a patent for a photographic paper which had actually been put on the market, and incidently had lost its producers a certain amount of money. The conditions had been very different then. There were a great many people who had to do everything for themselves, and photography had then been quite a delightful science, because, although one did not have to make the plates one had to dabble in everything. To-day an individual merely bought a Kodak or a snapshot camera, pressed the button and sent the films to a chemist to be developed. That was not photography. The amateur photographer had disappeared, but he had done very remarkable things. In the many fields of science the applications of photography which had taken the old amateur's place were equally fascinating, and, of course, were of very much more real value to the progress of the world. In a research laboratory, like the one in which he had the privilege of working at the present time, scientific men all over the world came up against difficult problems or new problems which they could not understand, and they asked the photographers to help them out. In that way photographers got a versatility of knowledge which could not be obtained in other branches of physics. He could have gone on for two or three hours, but he had only given a bare outline of the hundreds of things which came the way of photographers in the course of years. Possibly the only way of dealing completely with the subject would be either to give a course of lectures or to write a book. The applications of photography to-day were so many and so great that the man in the street had no knowledge of the part photography was playing in his everyday life.

The meeting then terminated.

EXTRA MEETING.

Friday, April 4th, 1924.

His Excellency The Brazilian Ambassador in the Chair.

The Chairman, in introducing Mr. Booth, quoted the opinion of Alexander Van Hamoldt, according to which the valley of the Amazon was the world's reservoir of the future. Of that mighty river the speaker only knew the mouth, having once been in Pará and witnessed the phenomenon of the pororoca, *i.e.*, the struggle between the fresh water and the tide. Mr. Booth, who was personally interested in the development of the Amazon, was about to give information to the audience, and to himself, which would certainly be profitable to their minds. The Brazilians did not know much about Brazil, possibly because they looked at her with eyes of sentiment, whereas foreigners saw it with eyes which were not obscured by sentimental prejudices. He had noticed, however, in England that when Englishmen spoke about Brazil, they did so with a good deal of benevolence. Englishmen saw in Brazil a new country well worth cultivating in view of future trade relations. Brazil appreciated England's sympathy in her efforts to become a great nation, and reciprocated that feeling by friendship and admiration for the British Empire.

The following paper was then read:—

THE AMAZON VALLEY AND ITS DEVELOPMENT.

By George Macaulay Booth,

Director of the Bank of England and of the Booth Steamship Company, Ltd.

The Amazon Valley drains an enormous area—on the south side more than half the Northern section of Brazil; on the west side Bolivia, Peru, Ecuador and Colombia, while on the North, both Venezuela and the Guianas of England, France and Holland come within its area.

The basin draining into this great river is as large as the whole of Europe. The Amazon Valley itself follows the line of the Equator, and for a distance of many miles on each side of the river the low-lying land is densely covered with forest. Here are found an astonishing variety of natural products and there is much to interest the naturalist, the botanist and the sportsman. Furthermore, the business man has been drawn into the area by reason of the great commercial value of many of the products that grow naturally in this vast wild region.

The district, as a whole, is scarcely developed owing to the difficulty of communication. This great basin is like Venice; it has no roads and there is no communication except by water, and I have been told that the network of rivers forming the Amazon system has a total length of 150,000 miles, of which about 30,000 miles are open to steam navigation. The total length of the Amazon River from east to west, that is to say, from Para to the Andes mountains, lying to the west of Iquitos, is about 2,500 miles. The total area drained by this great river falls little short of 3,000,000 square miles.

At the mouth of the Amazon its width almost approximates to a sea; the Northern edge being about 200 miles from the southern edge, while the delta in between is partially blocked by innumerable islands. At times, on its long journey, the Amazon becomes very narrow, but on the other hand, it frequently reaches a width of 10 miles, even as far as 1,000 miles from the coast.

A glance at the map will show that on the west coast the Andes lie about 300 miles from the Pacific. These mountains are over 16,000 feet high. In another 300 miles from their summits the land falls away just as steeply, and Iquitos, in the Upper Amazon, is only 1,200 feet above sea level, although more than 2,000 miles from the Atlantic mouth of the river.

This great mass of water flows sluggishly across the huge Continent of Brazil, the whole of which has been created during past ages from the detritus washed down by the torrential tropical rains which fall periodically among the ranges of the Andes.

The traveller by an ocean steamer meets the Amazon about 200 miles from land. While still on the blue waters of the South Atlantic, he notices the ocean taking on a yellowish tinge, which tells the story of the Amazon mud being carried out to sea by the great volume of water flowing through the 200 miles wide delta and mouth.

For many years no ocean liner dreamt of going further than Para. River boats, canoes and launches pushed their way up, but it was not until about 1880 that sufficient experience had been gained to make possible the commercial risk involved by sending an ocean vessel up to the great town of Manaos, just under 900 miles from Para. Some years later it was found possible to despatch ocean vessels to Iquitos, one of the most interesting ports in the world. It is a Peruvian Port and at the same time an Atlantic Port, for by Treaty the waters of the Amazon are International and vessels can pass freely from Para to Manaos, and Manaos to Iquitos without any special licences from the respective Governments.

The City of Para, which is the emporium of the Lower Amazon, is an early Portuguese Settlement, of which interesting traces can still be seen in the older parts of the town; but visitors will be particularly attracted by the tropical forest, with its vivid lights and shades.

The reason why so much difficulty was experienced in penetrating the interior from the coast was the impossibility of discovering, for many years, a channel through the innumerable streams of the Amazon delta. What was finally discovered as the key to this position is now known as the "Narrows." The river here is of ample depth, but is also so narrow that in many places one steamer cannot pass another, and a code of signals has to be arranged to avoid getting into difficulties. The forest on each side is particularly dense and this wall of green foliage stays with the traveller from the Delta to the Andes.

At some of the sharp turns it is possible for those on board ocean going vessels to pick the leaves off the overhanging trees of the equatorial forest, and so great is the displacement of water caused by the large vessel, that the little pile-dwellings on the low banks get swamped by a regular tidal wave. The native children, of whom there appears to be a large number in almost every thatched hut, thoroughly enjoy jumping into their canoes and tossing about on the big wash. Children who live in such surroundings have not, as you would expect, much trouble with clothing, and they can all swim, so that if the canoe gets swamped no harm is done. In this region there is a motto, "Plenty to eat and nothing to wear."

The caboclo, as he is called, who lives in such a hut, can get all the fish he wants to eat and grow all the oranges and bananas he desires, existing at the cost of very little labour. He is most disinclined to work, until tempted by the desire for modern appliances, such as gramophones and sewing machines. To earn enough money to purchase these he sallies forth, with much objection, to gather rubber or nuts.

The rubber is gathered by tapping a tree called the Angora Braziliensis and preserving the milk in smoke on a paddle, which is turned constantly and wrapped in the latex until the whole has become coagulated.

At certain points along the river road to Manaos there are beautiful clearings which enterprising planters have tried to turn into English parks to vary the monotonous lines of dense tropical forest. One of the largest fresh water fish in the world has its natural habitat in the Amazon. This fish is called the Piraracu, and it forms a staple diet among the natives. It has never been known to be caught by hook and line, but is harpooned, and the largest specimens measure 6ft. in length and 400 lbs. in weight.

Shoals of alligators are common sights at certain times and places. These repulsive beasts often bask in the sunshine and tempt the enthusiast with a rifle.

One of the most curious denizens of the forest is the ant-eater, a creature of whom all the other animals are afraid ; even the fierce jaguar respects the terrible claws of this beast, who is otherwise most gentle and feeble, gaining its livelihood by tearing asunder the large ant-hills, from which it gains its food. Another queer creature of this region is the piranha, or cannibal fish, which is easily the most dangerous of all. They exist in great numbers and are ferocious meat eaters. Any man or animal that enters the river where they exist will have the flesh taken from his bones in a few moments, and if he cannot reach the shore in a minute or two, will undoubtedly be destroyed.

I will now take you on to Manaos, between which place and Para there are nothing but tiny clusters of caboclo huts. Manaos is an old settlement and in the quay wall of Manaos Harbour there is set a stone taken to Brazil by the Jesuit Fathers in the 17th century. At this town the river rises and falls some 50 feet in the course of the year, which makes a complicated problem for those responsible for handling cargo from the Liverpool liners. At high river ocean steamers can come quite close up to the banks, but at low river they have to anchor over 100 feet away and the intervening gap is bridged by a floating roadway and an aerial cargo transporter.

Theatre Square, Manaos, is paved in the most curious way. It is tesselated, and is an imitation of the old Black Horse Square at Lisbon. Sobriety is desirable when crossing its zigzag flag stones.

Near to Manaos there are fields of the famous *Victoria Regia* Lilies. These lilies have enormous leaves of sufficient strength to support the weight of a little child.

Those of my age first heard of Brazil nuts, which are, of course, the speciality of this region, from "Charley's Aunt," whose husband, John Pedro, you may remember, came from Brazil where the nuts grow. Some 30,000 tons of these valuable nuts are produced every year and are shipped to the United States of America and to Europe. They do not grow as you see them in the shops, but are encased in a large pod, the size of a good-sized grape-fruit. This is split open and the nuts, as they are known to civilisation, are found inside.

The traveller who wishes to proceed further than Manaos has to endure a somewhat monotonous and difficult journey ; about 1,200 miles further on he reaches the town of Iquitos and in so doing he usually passes very interesting rafts of timber. These rafts are often of immense size and families of natives live on them, in thatch huts, for weeks at a time while they are floating down stream to the saw-mill.

Iquitos has the same physical difficulties as Manaos, the river rising and falling in the season well over 50 feet. In this town there are some 20,000 people and you will notice that for whatever else the town may be famous, it is not the pavement. Anything more appalling than the mud road in this Amazon town cannot be imagined.

Iquitos could at one time be reached by ocean vessels, but from this point onwards the traveller has to charter a launch or river steamer and here the country becomes more interesting ; one is closer to mountain atmosphere ; the heat becomes a little less intense and there is a sense of freshness in the air.

In my next picture you will see the village of Contamana. It looks charming in this photograph, but you can never trust the Amazon River ; and a few months ago the river decided to change its course and the whole of this street with its bamboo houses and shady avenue of trees was washed away and carried down stream.

The next photograph shows you a family going down for its annual holiday to Manaos. The man has done his rubber gathering and got what little money he wants for his holiday. He ties a few logs together, builds a little hut on his raft or balsa, and off he goes, just as you or I might start for Mentone or Monte Carlo, according to our taste.

My next photograph shows the limit of navigation by river steamer. That point is just 3,000 miles from Para and you will observe what a huge river the main Amazon still is. Here it is possible to hire a small launch at a little town called Massinia, and my slide shows the launch alongside the bank. In the background are the towers of the Wireless Telegraphy Station, which the Peruvian Government has built. I am told that now they have, also, an aerodrome, for Lima, the capital of Peru, is only a few hours' flight by air, though a long journey of a toilsome kind by any other route. You may well imagine that the river is a most suitable course for waterplanes, as they can come down on many occasions on the river if they happen to get into difficulties.

Here you see a canoe party. The river is narrow and growing very rapid and the boys have to push hard with poles.

My next slide is a typical hut where the traveller can sling his hammock and cook his meal, and if he is wise he will have brought his meal with him from Europe, as provisions on the spot quarrel terribly with an ordinary British digestion. The people are charming and hospitable and as delighted as they are astonished to see visitors.

On every point upon which I have touched, opportunities occur for science and business to take its pleasure and use its imagination. The whole place is astonishingly undeveloped and rich and its soil is refreshed every year, indeed, every month, by fresh supplies.

Those who are energetic can continue their expeditions up the Andes. My next photograph shows you literally the source of one of the innumerable courses of the Amazon. There you see a few horses in a valley about 15,500 feet above sea level and the little stream on the left hand side of the picture is starting on its long journey through the Great Amazon Forest to the Atlantic Ocean.

DISCUSSION.

At the invitation of the Chairman, various questions were put to Mr. Booth. One gentleman asked what was the best time to visit the Amazon Valley—whether it was inconvenient to go during the rainy season.

Mr. Booth replied that, broadly speaking, the best time to visit the Amazon was from March to August.

Mr. E. W. Richardson asked if any trouble was to be expected from the natives. Could English people travel freely without escort?

Mr. Booth said he was glad that the question had been asked, because he had accidentally omitted one sentence from his notes, which, owing to the last speaker's question, he was now able to bring in. It was as follows:—

> "Throughout the Amazon one meets these lonely Caboclos. They are one and all charming and hospitable. From first to last in my journey up the Amazon, not only in the big cities of Para, Manaos, and Iquitos, but in the smallest communities and in the single huts of the Caboclos a most pleasing feature to the English traveller was the whole-hearted kindly hospitality displayed on every side. No effort seemed to be too great to interest and entertain the visitors, who appear without notice and without any form of introduction."

When one got into the upper reaches of the Amazon and its tributaries, however, one had to be a little more careful, because in that territory, although there were not many, there were a few natives who preferred human flesh to fish. A traveller must not proceed too far into those regions without a good guide. As a matter of fact, he himself had received nothing but friendliness, but one or two great travellers who had spent a long time there, did know quite definitely that a number of tribes still remained, especially in the remote Peruvian forests, with whom it was best to be on rather distant terms.

Dr. Rushton Parker enquired if the native rubber was equal to plantation rubber in quality. He rather supposed that it was not, and that it would not fetch the same price as plantation rubber.

Mr. Booth said it fetched very much the same price. Those who believed in Para rubber thought there was nothing like it. It had to be remembered, however, that the Mad Hatter, in "Alice in Wonderland" said there was nothing like hay for a cold; but when questioned about it he did not say there was nothing better. Personally he was one of those who thought Para rubber, which was gathered from the very biggest trees, if perfectly prepared, produced a latex which was probably a little finer than anything else; but he was prejudiced. Para rubber was certainly of very fine quality.

Mr. J. A. Murray said, after twenty years' experience of Amazon rubber, he could unhesitatingly say that, in the opinion of the rubber trade, and everybody else, Para rubber was about one hundred times better than plantation rubber. Plantation rubber had been exported to the East from the Para, and it had got watered down and watered down. It was just like thick blood and thin blood. The Eastern rubber was the thin blood and the Para rubber was the thick blood.

A lady member of the audience enquired if there was a prepared drinking water supply in the great cities of the Amazon Valley, or was it all pure Amazon water?

Mr. Booth replied that there was prepared drinking water in all the three big towns. In Manaos it was very difficult to improve on the pure Amazon water, because Manaos was not on the main Amazon river, but it was on the Rio Negro, which looked like a Scotch burn; it was beautifully bright clear crystal water. At Para the water was full of mud and had to be filtered, but there were modern up-to-date water works which provided an excellent water.

Mr. E. W. Richardson asked whether a knowledge of the Portuguese language was necessary in travelling through the valley; also were French and English of any use?

Mr. Booth said in Para and Manaos the cultivated city dweller talked some English and some French, but outside of those two towns and Iquitos he did not think anything but Portuguese and Spanish would be of any use. It was not a difficult thing to acquire enough knowledge of those languages for anyone who already knew French, but he would not recommend anybody to travel alone in the distant parts without a fairly good knowledge of Portuguese. Many of the natives did not speak Portuguese at all, but quite unknown tongues.

Mr. Rushton Parker said he noticed nothing had been said about coffee. Was not coffee grown to a large extent in the Amazon Valley?

Mr. Booth said that he did not think coffee was grown there. Coffee was the great product of San Paulo and Santos.

A question was then asked as to exactly where was the Italian colony of farmers to which Mr. Booth had referred. Was it easier to get at from the West coast than by the long journey up the Amazon from the East coast? To what extent was it in Peruvian territory?

Mr. Booth replied that the Italian farmers were in Peru. If it were taken that the Pacific was 300 miles from the top of the Andes and the main swamps of the Amazon were from 300 miles more down, one was still in Peru. The Italian farming group were about half way up—about 6,000 feet up in the Peruvian Montana—the Andes of Peru—on the eastern slopes. He had found quite a number of Italian farmers there. At every five or six miles he had come across an Italian farmer.

Mr. G. M. Ryan asked if the river Amazon was controlled at all in any part of its long length. If it was not controlled he could quite understand why the country was not developing. The conditions would be so unstable that people would not settle there. Floods would always be rising, and the population would never increase without permanent conditions.

Mr. Booth said that was one of the great difficulties of the territory. It was so large an area that no control had been attempted. It had merely been discovered that certain places appeared to be sufficiently high up out of the water to be stable, and those places had been selected for towns. Other places existed for towns, but they were rather far away from the rivers, and it required a good deal of enterprise to make roads and ways up to them. Some of these places were on hills, several hundreds of feet above the river, but they were surrounded by the densest forest, which undoubtedly made development very arduous work. There was no control in the sense of managing the water of the river. There was, however, control over people's rights; one had to get a licence for staking out a position. Another point was that the river arose in so many countries, that control would be very complicated. Probably that had been a great cause of retardation of development.

Dr. Rushton Parker asked whether there was much mixture between the real native and the Portuguese.

Mr. Booth replied that at the present time, in the neighbourhood of Para and Manaos, it would be very difficult, as far as the real native was concerned, to find any difference as a new race there, but the difficulty was complicated by the fact that there were large negro settlements as well. The three races were the actual Indians, the true Portuguese and the negro. Ethnologically he believed to-day it was a very complicated and curious development.

The Chairman in moving a vote of thanks to Mr. Booth for his lecture, said he had no doubt the audience were grateful for the opportunity of thinking about a territory otherwise than merely as a land of rubber and nuts. Mr. Booth had been particularly kind in avoiding making any remarks about certain unpleasant matters in connection with that territory, for instance, the rather incautious way in which its administration had lately been conducted. Mr. Booth had only mentioned agreeable things, as probably he thought there might be among those present some who had cause for complaint by reason of having invested in Para, or Amazon stock. He thought, however, that that should not prevent people from thinking kindly of the country for the future, if not for the present. Men passed, but land stood, and even if the Amazon did change its course from time to time, the land was there as a reservoir for the activities of man in the more or less remote future.

The vote of thanks was carried unanimously and the meeting terminated.

NOTES ON BOOKS.

The Works of Sir John Soane, R.A. By Arthur T. Bolton, F.S.A., F.R.I.B.A. The Sir John Soane Museum Publications, No. 8. 6*s*. 6*d*.

This work gives an account of the architectural career and work of Sir John Soane. The author, who is well-known as the Curator of the Soane Museum, has unrivalled opportunities for the study of his subject, and, as he has shown in former volumes published in this series, he is filled with genuine enthusiasm for the work of the master. Readers of the present book will probably turn with particular interest to Mr. Bolton's account of the Bank of England. This is no doubt the finest specimen of Soane's Art, and the author has very rightly devoted to its description two chapters, illustrated by no less than forty illustrations, in addition to a frontispiece, an aerial view, which gives one a remarkably good impression of the size and proportions of this great building.

Soane began his work on the Bank in 1788, and it was not completed until 1823, when he was sixty-nine years of age. Mr. Bolton gives minute details of the building including many particulars of the cost. The estimated total for the expenditure over the forty-five years was £866,602 0*s.* 8*d.* At the time when the building started, bricklayers' wages were 3*s.* 4*d.* per day, and labourers' wages 2*s.* 2*d.* The present wages for a day of the same duration would be for bricklayers, 19*s.* 6*d.*, and for labourers, 14*s.* 9*d.* The cost of materials has risen in much the same proportion. Brickwork, which cost £9 per rod, now costs about £30, while tiles have risen from 30*s.* to 100*s.* per thousand.

Soane was an enormously hard worker—his office hours were 7 to 7 in summer and 8 to 8 in winter. He thus got through a great quantity of work, and an imposing list of his buildings appears in an appendix. Other appendices include lists of Soane's private clients, and of his pupils, assistants and clerks—in short, Mr. Bolton has been at the utmost pains to omit nothing which may throw any light on the work and methods of the master.

MANGROVE BARK IN SUMATRA.

Up to the present time, writes the United States Consul at Medan, the mangrove bark produced in the Medan district has been an article for local export only, most of it being shipped to Penang in the Straits Settlements. At this point it is gathered for trans-shipment in larger quantities to Hongkong, Amoy, and even as far North as Shanghai. Small lots of 1,000 or 2,000 bundles have also been forwarded from Penang to the United States.

Ninety-five per cent of all the mangrove bark exported from the Medan district grows along the low swampy north coast of the Province of Atjeh in the neighbourhood of Langsa, the chief port. A small quantity comes from the little port of Idi, farther west. About 60,000 bundles of bark are exported monthly from Atjeh. Each bundle is about 27 inches long and weighs 40 catties or 54 pounds. The total thus approximates 1,500 tons a month or 18,000 tons each year.

There are two species of mangrove tree—the Tengar, with reddish brown bark, which is first quality, and the Bacau, or second quality, the bark of which has a whitish surface. Of the total quantity of bark produced 60 per cent is of the Tengar variety and 40 per cent of the Bacau. The mangrove tree grows to a height of 70 to 80 feet above the water level. The trees are cut down and the bark is stripped off in lengths of 27 inches. The bark is then dried in the sun and bundled together with strips of rattan. When shipped as deck cargo, as frequently happens in these eastern waters, the bundles of bark are placed in sacks as a protection from the weather.

The collecting and local marketing of the mangrove are done wholly by Chinese. No attempt is made to boil the bark to obtain the extract used in tanning. It is understood that this is done in some parts of Borneo where mangrove bark is gathered. Two European companies hold mangrove swamp concessions and grant rights to the Chinese to gather the bark upon the payment of a royalty. The Dutch Government also grants rights to Chinese to gather bark on Government swamp land and collects a small tax for each bundle gathered.

TURKISH GUM TRAGACANTH PRODUCTION.

Gum tragacanth is the product of several species of shrubs, genus Astragalus. The shrubs grow to a height of three or four feet, and are found in a wild state on the highlands and mountains of Turkey, Persia, and Syria. No special cultivation has ever been attempted. The greater part of the Anatolian crop is gathered by peasants each year during the months of June and July.

According to a report from the United States Trade Commissioner's Office at Constantinople, the most important regions producing gum tragacanth are Caesarea, Angora, Yosgad, Karaman, Michalitch, Konia, Karahissar, Everek, Nigde, and Nidel. The first five centres named probably produce the best qualities. When collected and dried, the gum is packed in sacks, taken to the nearest village, and sold to jobbers, who are usually the agents of the exporters in the large ports. Thereupon it is transported to Constantinople or Smyrna, where it is graded for exportation. The entire product is exported.

Tragacanth is graded according to quality, irrespective of the point of origin, and usually according to the following classification.

Firsts (fiores or extras)—the finest white, translucent flakes.
Seconds—yellowish flakes of good quality.
Thirds (Biondos)—clear, yellow flakes.
Fourths—dark yellow and opaque gum.
Fifths (Scarto and terreuses)—flakes of all cuts which are damaged by rain and dirt, mixed and sold at a low price.

The gum comes from the producer in sacks containing about 60 okes each (oke = 2.8 pounds). The finest qualities are repacked for export in wooden cases containing about 120 kilos (kilo = 2.2 pounds), while the inferior grades are shipped in jute sacks, 75 to 100 kilos to the sack.

In the years immediately preceding the World War, production is estimated to have been about 5,000 to 6,000 sacks annually. During the war it was greatly neglected and barely reached 1,500 sacks. Most of the peasants were in the army and transportation was inadequate. Very small amounts were shipped to the central European countries until the last two years of the war, when the annual exports were from 800 to 1,000 sacks. Production rose steadily after the armistice and is now approximately 5,000 sacks per annum.

A certain amount of Persian gum tragacanth comes to the Constantinople and Smyrna markets and is re-exported. This gum is of a very fine quality, being white and translucent, and is produced in flakes and ribbons. In many respects it resembles the Anatolian firsts, but has a higher yield than the latter. Persian gum is used chiefly in medicine and in the better grades of confectionery. Syrian gum, small quantities of which used to be handled in Constantinople, comes in thin, vermiform pieces. It is very translucent, yields more than Anatolian gum, and is used for purposes similar to those of the Persian gum. Bitlis gum or "hog tragacanth" is the product of a species which grows in the region of Bitlis, and throughout Kurdistan, and is used largely for dressing and stiffening rough cloth materials, such as jute sacking.

MANUFACTURING INDUSTRIES OF MEXICO.

In spite of the prominence of minerals, oil and agricultural products in the export statistics of Mexico, that country is also a manufacturing country of some importance; its total production of manufactured articles is claimed to exceed that of any other Latin-American Republic. This is due partly to natural advantages and partly to the policy of encouraging the establishment of new industries by the imposition of high, and in some cases prohibitive, duties on foreign goods.

Of the industries which flourish under this protective wall, writes H. M. Consul-General at Mexico City, probably the most important, from the points of view both of capital invested and of value of output, is that devoted to the manufacture of cotton textile goods. The largest factory is situated in Orizaba and is equipped with machinery of a modern type which is capable of performing all the operations from the cleaning of the raw cotton to the dyeing of the finished cloth. More than 100 other factories are situated throughout the Republic and, although the industry is suffering at present from depression, owing to the high price of the raw material, combined with over-production and lack of demand, there is no doubt that it is an economic factor of great importance in the manufacturing development of the country.

The manufacture of tobacco, especially in the form of cigarettes, for which the demand seems to be inexhaustible, is also an important and flourishing industry. Two large factories of the most up to-date style are established in Mexico City and there are scores of smaller factories for producing cigars and cigarettes scattered throughout the Republic.

Boots and shoes are also manufactured on an increasing scale. In Mexico City there are two large factories owned largely by British capital, besides others of considerable importance. The quality of the goods produced is high and, although it cannot equal the best class of British-made shoes, it is equal to the requirements of the public. For this reason the importation of footwear seems bound to decline in the future.

The brewing of beer, the distillation of spirits, and the manufacture of wines and beverages are all flourishing industries.

Paper is made in the Republic, there being two large mills devoted principally to the production of newsprint, in which they are capable of satisfying the requirements of the country. They also make a certain amount of bond, writing and other papers, but have not yet reached the stage where they can compete with the imported article along these particular lines.

Cement of good quality is manufactured locally, one important factory being controlled by British interests. Structural steel and ironwork, and other iron and steel products are well represented. The manufacture of jute bags at Orizaba is carried on by a very important British firm.

Other articles of local manufacture of importance are:—woollens, furniture, hats, chinaware, glass bottles, soap, jams and preserves, matches, clothing and rubber goods including motor tyres, explosives, musical instruments, vehicles, &c.,

A NEW HARBOUR FOR INDIA.

According to the *Indian Textile Journal*, there is now every prospect of the long-contemplated project of a harbour at Cochin becoming an accomplished fact in the near future. All who are familiar with India and Indian shipping have long felt the desirability of having another harbour on the West Coast of India, south of Bombay, where vessels could discharge cargoes all the year round, and the agreement which has just been signed between the Madras Government and the two adjacent Native States interested in the project marks a great step forward towards the realisation of this need. In 1918 a scheme was submitted to the three States concerned—Madras, Cochin and Travancore—for the development of the port of Cochin at an estimated cost of Rs. 203¼ lakhs. It was subsequently decided to carry out this scheme in four different stages—the first of which was to be the opening of a bar at a cost of Rs. 9 lakhs. It was, however, found necessary to first of all carry out extensive dredging operations and these were not completed until May of last year, when a channel 150 feet wide and 17 feet deep was completed through the bar and also channels inside the bar to prevent overflowing during the monsoons. Careful observation was kept during the last monsoon and the conclusions resulting from these appear to be favourable, so that it is hoped that the other parts of the original scheme may ultimately be carried out. Until the trade of the port reaches an average of Rs. 15 crores a year it will be regarded as a "minor" port, and the three adjacent States will be responsible for the financial working of the scheme. When the aggregate trade averages over Rs. 15

crores, the port will become a "major" port and automatically pass under the control of the Indian Government, who will re-imburse the expenses incurred in the carrying out of the first stage of the scheme. A Port Trust is to be formed upon similar lines to those now in existence at Calcutta, Bombay and other Indian ports. It is claimed that this new harbour, when completed as planned, will make it possible for vessels to enter and discharge and load cargoes all the year round.

TUNISIAN TUNNY FISH INDUSTRY.

According to the recent annual report on the trade of the Regency of Tunis, by the Acting British Consul General at Tunis, the tunny fish industry, a source of considerable wealth in Tunisia, is both curious and of considerable commercial interest. The fish is noticeably larger than the tunny which is caught on the coasts of France and Spain, and the methods used for catching it are very different. Whereas the "Gascony" tunny does not generally exceed 60 pounds in weight, and is usually caught with a line, the Mediterranean tunny runs to some 400 pounds in weight, and is only taken in nets. Its flesh is of darker colour and coarser texture, and is used almost entirely for canning in oil. 95 per cent. of the fish caught in Tunisia is exported, mainly to Italy, the rest being consumed locally.

The most important tunny fishing station is that of Sidi Daoud on the Gulf of Tunis, nearly opposite Carthage. A highly-organised fishing camp has been constructed there together with a canning factory. The tins are actually made on the spot, as well as the wooden cases ready for export, although the locality is served by no railway line, nor even a good road. Both the tinplate used and the timber, together with all other material, such as olive oil and salt, have to be brought to Sidi Daoud either on rough country carts or, more often, by small sailing vessels and light steam craft plying across the Gulf.

This fishing station is only in activity during the months of April, May, June and July, and of this period little over one month, namely, June, is actually taken up with the fishing, the rest of the time being used for preparation and organisation.

A good average day's haul is 1,000 fish averaging some 200 lbs. each, namely, a total of 100 tons. A good average total for the season is 1,000 tons or more.

THE GINGER INDUSTRY OF CANTON.

Dried and preserved ginger, as well as the raw product, are exported from the Canton district, although Hongkong is the centre for the exportation of ginger. Ginger root from Canton and other points is imported into Hongkong, where it is preserved and dried for shipment to consuming countries.

The year 1922 was a favourable one for the ginger industry. The exportation of fresh ginger from Canton increased from 7,046,074 pounds, valued at about £25,000 in 1921, to 9,779,357 pounds, valued at about £38,500 in 1922. Only a small amount of preserved ginger was exported from Canton, as most of the ginger is preserved at Hongkong.

According to the United States Vice-Consul at Canton, the ginger factories there buy ginger from a few Chinese dealers, who collect from many small up-country growers. The ginger is shipped to Canton by junk. Stem ginger, or the young tender shoots of the plant, is cut up into small sizes suitable for sale. Cargo ginger is treated as it comes from the growers and is brought into Canton in pieces weighing from four ounces to a pound.

After arrival at the factory the ginger is given a preliminary washing in the river. Then it is put into a vat with a capacity of about 360 catties (equivalent to 480 pounds) and boiled for about an hour. After draining off the water, ginger and sugar are mixed in equal proportions, with enough water for boiling. This mixture is boiled in the vat for an hour, and the resulting preserved ginger is packed in casks of 168 catties (224 pounds) for shipment abroad. It is also shipped in cases containing jars packed in straw. The cases are made of local timber.

The same process, up to the boiling with sugar, is followed in the manufacture of dry ginger. In this case very little water is added after the ginger is mixed with sugar. The ginger is boiled until dry, after which it is removed from the vat and packed in one-pound tin boxes.

MEETINGS OF THE SOCIETY.

INDIAN SECTION.

MONDAY JUNE 30, at 4.30 o'clock.—J. C. FRENCH, I.C.S. "The Art of the Pāl Empire in Bengal." THE RIGHT HON. THE EARL OF RONALDSHAY, G.C.S.I., G.C.I.E., will preside.

DOMINIONS AND COLONIES SECTION.

MONDAY, JUNE 16, at 4.30 o'clock.—C. V. CORLESS, M.Sc., LL.D., "The Mineral Wealth of the pre-Cambrian in Canada." SIR RICHARD REDMAYNE, K.C.B., M.Sc., M.Inst.C.E., M.I.M.E., M.I.M.M., F.G.S., Chairman-Governor, Imperial Resources Bureau, will preside.

Journal of the Royal Society of Arts.

No. 3,735. VOL. LXXII.

FRIDAY, JUNE 20, 1924.

18 JUL 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

FINANCIAL STATEMENT FOR 1923.

The following statement is published in this week's *Journal* in accordance with Sec. 40 of the Society's By-laws:—

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One-hundred-and-Seventieth Annual General Meeting, for the purpose of receiving the Council's Report and the Financial Statement for 1923, and also for the election of Officers and new Fellows, will be held, in accordance with the By-laws, on Wednesday, June 25th, at 4 p.m.

(By Order of the Council)

George Kenneth Menzies,
Secretary.

DOMINIONS AND COLONIES SECTION.

Monday, June 16th, 1924; Sir Richard Redmayne, K.C.B., M.Sc., M.Inst.C.E., M.I.M.E., M.I.M.M., F.G.S., Chairman Governor, Imperial Resources Bureau, in the Chair.

A paper on "The Mineral Wealth of the Pre-Cambrian in Canada" was read by Mr. C. V. Corless, M.Sc., LL.D.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

TWENTIETH ORDINARY MEETING.

Wednesday, May 7th, 1924.

Admiral of the Fleet, Sir Herny B. Jackson, G.C.B., K.C.V.O., F.R.S., M.I.E.E., in the Chair.

The paper read was:—

WIRELESS NAVIGATION.

By J. Robinson, M.Sc., Ph.D., F.Inst.P.,

Head of Wireless and Photography Department, Royal Aircraft Establishment, Farnborough.

Some features of wireless navigation are already well known. The basis of the subject is that it is possible to determine the direction towards a wireless transmitting station, and the instruments for doing this are usually called direction finders. Most people are aware of the uses made of these instruments by our Fighting Forces during the war. In Zeppelin attacks, our organisation of direction finding stations, with their means of communicating with London, gave our headquarters staff immediate information as to the position of the Zeppelins, so that we were warned of the approach of the airships, and each district was darkened as required. The Zeppelins themselves transmitted, so that the German direction finding stations could work out the position of the airships, and it is of interest that in these cases wireless navigation proved both of use and disadvantage to our late enemy.

Again, our direction finding stations were of use in finding the whereabouts of German submarines. The submarines were fitted with wireless transmitting and receiving apparatus for purposes of communication with their bases. When they used their transmitters, bearings were found on them by our various direction finders, and their positions were discovered. The fact that our stations were kept most busy at nights was testimony to the efficiency of our various defence methods. An interesting episode happened in the Mediterranean, which was only discovered by us after the war. The enemy knew of our methods of sending out wireless broadcast signals giving the position of any enemy submarine, and on occasions, where a submarine was not sure of its own position, it came to the surface and made a transmission, knowing that our direction finding organisation would give its position. On receiving the information required the submarine naturally departed as far as possible from the position indicated to our submarine hunters.

Some time ago the fact was disclosed that our direction finders had some important influence during the Jutland Battle. Early information was received of the movements of the German Fleet, and Admiral of the Fleet Sir Henry Jackson, who was then First Sea Lord, was able to issue early instructions to our own Naval Forces.

These facts show that Great Britain was in the forefront of the development of wireless navigation, and we can claim to have carried the development to a higher pitch than any other nation during the war. Post-war application perhaps does not leave us with the same superiority.

Long before the advent of wireless, navigation had become very highly developed. Many methods were available to give the mariner information of his position and of the course he should steer. These methods, however, were not infallible, as ships were lost owing to faulty navigation. Wireless gives a further method for determining position, and as a navigational method it is already diminishing the number of ships lost, and by more universal application it will undoubtedly add materially to the safety of life at sea. In the cases where the better known navigational methods fail, *i.e.*, in fogs, or during persistent cloudy weather on long voyages, wireless is exceptionally useful. Unlike light, wireless waves are unaffected by fog. Thus by the aid of wireless, ships can proceed during fogs with an accurate knowledge of their positions, and so considerable time can be saved.

Another aspect of navigation must nowadays be considered, *i.e.*, for aircraft. In this case wireless must play an even greater part than it does for ships, and so much so that it will become absolutely essential for aircraft. One reason for this is that drift plays a much more important part in the air than it does at sea, so that dead reckoning methods are not so easy to apply. A cross wind of thirty miles per hour has a serious influence on an aeroplane doing 100 miles per hour, and the wind may change in force and direction without the pilot being aware of it. In cases of over sea flights and of flights above clouds, it is thus of great importance to make use of all possible navigational methods, and wireless will play a very important part.

From the navigational point of view there is nothing new for mariners to learn about wireless navigation. The method is analogous to that of taking bearings on lighthouses and on known points on the coasts. Wireless introduces other fixed points, *i.e.*, wireless shore stations, with the added advantage that these stations can be at ranges much greater than the eye can see. Ranges of hundreds (even thousands) of miles can be used, though the greatest utility for ships will probably be under one hundred miles. On a point of application there is one difference from visual bearings, which is that for long distance wireless bearings it is necessary to take into account the curvature of the earth. Wireless bearings are great circle bearings, and must be treated accordingly when transferring to mercators or other form of chart.

When two or more bearings are obtained from different wireless stations, one's position can be plotted on a chart, see Fig. I. Wireless bearings are usually obtained with an accuracy of 2°. This may seem crude to some navigators, especially when compared with the precision of their astronomical

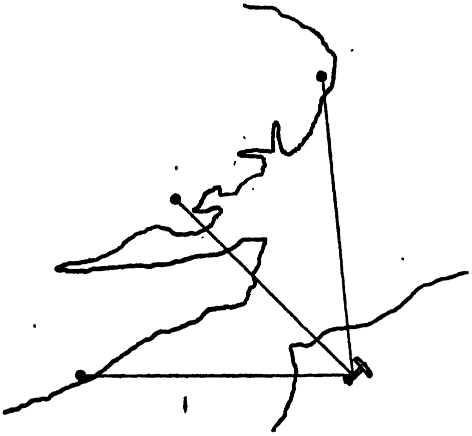

FIG. 1.

Method of locating position by means of three Fixed Stations.

observations. It is not so crude as it appears at first sight, as a number of wireless bearings from different stations can be obtained, and on plotting the various bearings they will cut each other to form various triangles, and one's most probable position can be obtained with reasonable accuracy. Again, positions can be obtained from time to time and checks obtained by the aid of dead reckoning. Again, in regions where wireless navigation is most useful it will usually be possible to have a number of wireless stations at comparatively short ranges, say, not exceeding 50 miles, in which case an accuracy of 2° is quite good.

The principle on which most direction finding systems depend is that of a single loop consisting of one or more turns of wire. If such a loop is joined in series with a tuning condenser, and suitable receiving means employed, it has the following properties. Suppose that the loop is arranged to rotate about a vertical axis, and that we tune in to waves coming from any particular station, when the loop is rotated it will be found that the signal strength alters, and that in one complete turn there are two positions where the signals are loudest, and two positions where the signals vanish. The two positions of maxima are directly opposite to each other, in other words, 180° apart, and the two positions of minima are also directly opposite to each other, the minima being at right angles to the maxima. When a maximum is obtained, the plane of the loop is pointing directly at the transmitting station, and thus when the minimum is obtained the plane of the loop is at right angles to the direction towards the transmitting station.

The reason for this change of signal strength as the loop rotates is as follows :—Wireless waves travel over the surface of the earth. Another name for wireless waves is electro-magnetic waves, a term which implies that there is an electric component and a magnetic component of the wave. There are thus three features of the waves, the direction of transmission, the electric, and the magnetic fields, and these three are at right angles to each other, see Fig. 2. The electric force is normally vertical and the magnetic force horizontal. The fact that we are dealing with waves means that both these fields are alternating rapidly. From the laws of ordinary electro-magnetic induction, it is known that if the magnetic field cutting through the plane of a loop changes, an electro-motive force is produced in the loop. For every position of this direction finding loop, except where the plane of the loop is parallel to the direction of the magnetic field, the magnetic lines of force cut through the loop and thus produce an electro-motive force. Where the magnetic lines are in the plane of the loop, no electro-motive force is produced at all. This position, by reference to Fig. 2, is obviously for the plane of the loop at right angles to the direction of the waves, the maximum cutting of the lines of force through the loop is obviously where the plane of the loop is in the direction of the waves, and between these two positions there are produced varying degrees of electro-motive force. We thus see why maxima and minima are obtained, and by using

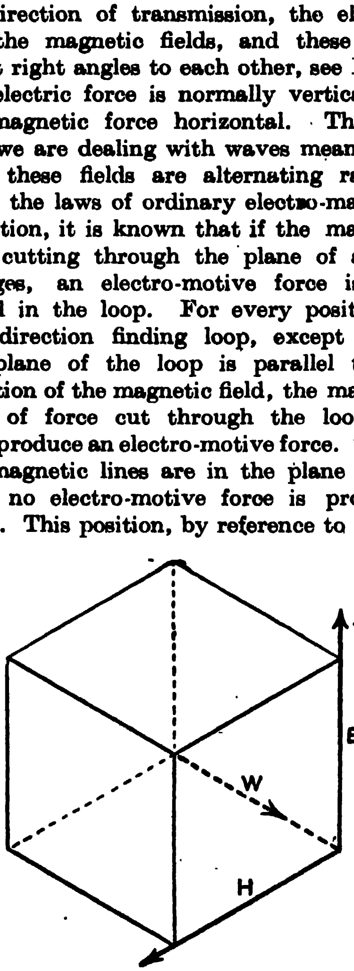

FIG. 2.

Relationship between Electric and Magnetic Fields and Direction of Propagation of Waves.

suitable receivers a curve similar to that shown in Fig. 3 is obtained, which shows the relationship between the position of the loop with regard to the transmitting station and the amount of energy picked up by the loop. In this diagram the energy absorbed from any given direction is proportional to the length of a line drawn in the required direction, from the centre of the degree circle to the point at which it cuts the figure-of-eight curve.

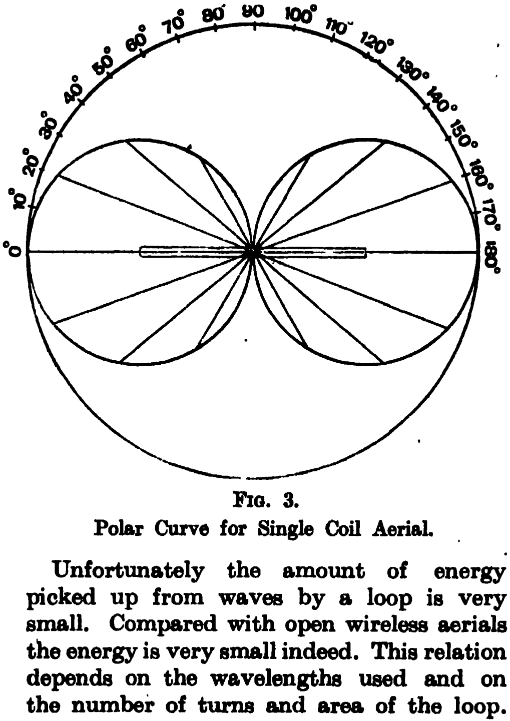

FIG. 3.
Polar Curve for Single Coil Aerial.

Unfortunately the amount of energy picked up from waves by a loop is very small. Compared with open wireless aerials the energy is very small indeed. This relation depends on the wavelengths used and on the number of turns and area of the loop. Consider an open aerial 90 ft. high and a square loop of 10 turns of 3 ft. side. On a wavelength of 1,000 metres the open aerial receives 300 times the electro-motive force received by the loop. When the wavelength is 2,000 metres this ratio is 600, and when 500 metres, the ratio is 150; the shorter the wavelength the better is the loop in relation to the open aerial. It would thus appear advisable to increase the size of the loop as much as possible. There are limits to this, however, from the point of view of convenience, and, further, from the point of view of wavelength. Although the directional properties of loops have been known for some considerable time, the small amount of energy they receive prevented use being made of them for directional purposes, to any extent, until the advent of the thermionic valve, which enabled very sensitive receivers and amplifiers to be designed.

By reference to the curve in Fig. 3, it will be seen that the most sensitive position for determining direction with a single loop is at the minimum, and that the determination of the maximum with any accuracy is impossible; this is because the variation of signal strength at the maximum is very slow. The position of the minimum can be determined with considerable precision by rotating the loop through the minimum position until signals are heard on both sides of the minimum. On a circular scale the readings on both sides of the minimum are noted and the mean angle worked out. A typical example of a single loop direction finder is shown in the slide. This form of loop, which is usually known as the single loop method, is used in the United States and in France, and to a certain extent in Great Britain.

BELLINI-TOSI SYSTEM.

Owing to the small amount of energy picked up by loops, in the early days it was necessary to use large loops, which could not be conveniently rotated. A form of apparatus of this nature was invented prior to the war, and is known as the Bellini-Tosi apparatus. This apparatus makes use of fixed loops which may be of the dimensions of 100 ft. square or even greater. Two loops at right angles to each other are used and tuned up separately. By means of an instrument known as a radiogoniometer, shown on the screen, a small rotatable coil inside this instrument is coupled loosely to two coils at right angles, these coils being respectively in the circuits of the separate aerials. It is found that by suitable connections, as this moving coil is rotated, maxima and minima are obtained as in the case of a single loop, and that these maxima and minima correspond exactly with the direction of the incoming waves. The explanation of this has been given on many occasions and need not be entered into here. Recent developments of this apparatus have led to the abolition of the tuning condensers in the main aerials. Fig. 4 shows a complete connection for this form of apparatus joined up to a single valve acting as detector. This form of apparatus had considerable use during the war, and its development to a stage of practical utility was due to British engineers, particularly Round and Prince.

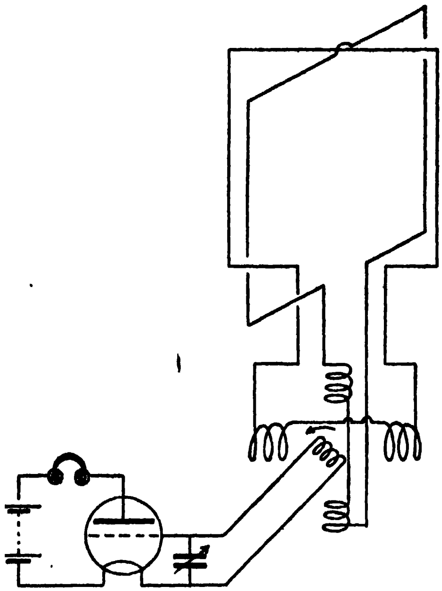

FIG. 4.
Bellini Tosi D.F. System.

ROBINSON SYSTEM.

Another system for determining the direction of the waves also makes use of two coils at right angles to each other, but in this case the two coils are capable of rotation together. These coils are used in series, and a typical set of connections is shown in Fig. 5. The object of this system is to allow bearings to be taken whilst an audible signal is heard, and it is in this respect distinct from the two preceding systems. Such a system is obviously of great utility in many circumstances. First, it enables the signal to be read at the same time that a bearing is being taken. Secondly, in cases where external noise is very bad, as in the case of aircraft, this external noise would tend with minimum systems to make the angle of a minimum signal very wide and thus the determination of bearings inaccurate. This system is sometimes called the maximum system, because it enables the maximum position of one coil to be determined. The coils being at right angles, when one coil is on the maximum the other coil is on the minimum or zero. Suppose that one coil, called the main coil, is used alone, a rough determination of the maximum can be obtained. Now, by the use of a switch one can introduce the second or auxiliary coil to add its effect to that of the main coil. If the main coil is accurately on its maximum, the auxiliary coil will be accurately on its zero, and thus the introduction of this latter coil should make no difference, variation in tune being specially compensated for. If it does make any difference to the strength of signal then it is necessary to rotate the system slightly in order to obtain the condition where the introduction of the auxiliary coil makes no difference to the strength of signals. In actual practice the method in use is to reverse the connections of the auxiliary coil, which in effect means that the effects of this coil are added to or subtracted from those of the main coil. This system is capable of very great accuracy by making the size of the auxiliary coil many times greater than that of the main coil; the adjustment of the coil can be set to within one-tenth of a degree. In actual practice this accuracy is too great, and the ratio of the coils is chosen about two or three to one.

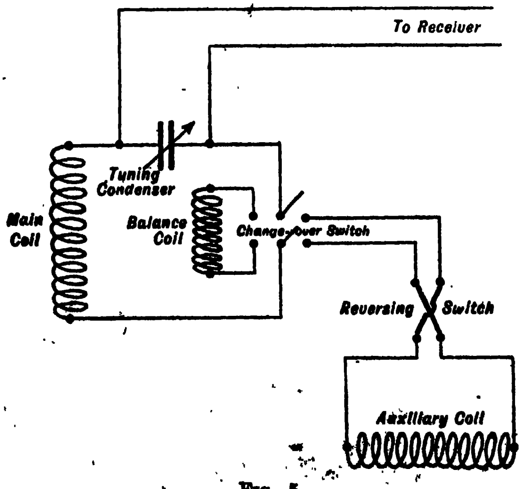

FIG. 5.
Robinson D.F. System.

APPLICATION.

Having described the various reception methods for determining the direction of wireless waves, the question arises as to how these instruments can be used for actual wireless navigation, in other words, whether the instruments should be placed on shore or on the ship or aircraft. We shall first discuss the system where the direction finding stations are on the shore. In this case a system of direction finding stations is worked out so that reasonable accuracy is obtained from whatever direction the ship may be approaching, i.e., it is arranged that the cuts should always be at as large an angle as possible. Obviously, if two bearings cut at a very fine angle the deduction of position is liable to serious error, because, the bearings being nearly parallel, the smallest error in one will make a big difference in the point at which they cut. The system of direction finding stations is then linked up with one central station by land line or by transmitting wireless stations. It is preferable to use land line wherever possible. The procedure for determining position is for a ship to make a call asking for its position. Each direction finding station works out the bearing and communicates its result to the central station, where the position of the ship is plotted from these various bearings. As soon as this is determined the central station communicates the position by wireless to the ship. A certain length of time is required for this process, of the order of five minutes, and only one ship can be dealt with at a time. Any accuracy that is required can be obtained by increasing the number of direction finding stations on the shore. This system has had considerable application. It is the system that was used by the Zeppelins during the war in their attacks on England. Again, it is the system that was used by our forces to determine the position of the enemy submarines. Obviously for war purposes it has the great disadvantage that the position is disclosed to the enemy as well as to one's friends, as in the case of the Zeppelins. The system is used to some extent in England at the present time, stations being at Flamborough Head, the Lizard and Berwick-on-Tweed. The greatest application at the present time of this system is being made in the approaches to New York Harbour. The slide shows the thoroughness with which the United States Authorities are making use of this system. A large number of direction finding stations are used, and it is stated that twenty thousand bearings are given every year. Again, this system is being used on the Civil Air Route between London and Paris. On the British side direction finding stations are installed at Croydon and Pulham. An aeroplane asks for its position by wireless telephony. Both Pulham and Croydon work out bearings, the Pulham bearing being communicated by land line to Croydon, where the position of the aircraft is worked out and transmitted.

An alternative system to the preceding is to instal the direction finding systems on the ships themselves. This method has many advantages over the preceding. It enables each ship to take bearings of any transmitting station in any part of the world, whereas the former system restricts the use of wireless navigation to certain regions. It enables many ships to determine their positions simultaneously, whereas the former system is comparatively slow. By this system every ship which has the apparatus installed can determine its position at any time. Again, the captain of a ship much prefers to trust bearings determined by himself or by personnel under his control. Again, a ship can determine its position without disclosing its whereabouts to any possible enemy, and it is thus the system which will be most applicable in war. It has certain difficulties, but these are completely out-weighed by the preceding advantages. The principal disadvantage is that it is necessary to instal the apparatus very carefully on each ship. Further, on metal ships, the ship itself has an influence on the bearings determined and corrections are necessary. The corrections to be applied can, however, be determined, and in certain cases the errors can be adjusted as in the case of the corrections and adjustments for the magnetic compass on steel ships. A typical error curve is shown in Fig. 6. Once such a curve has been obtained allowance can be made when bearings have been taken.

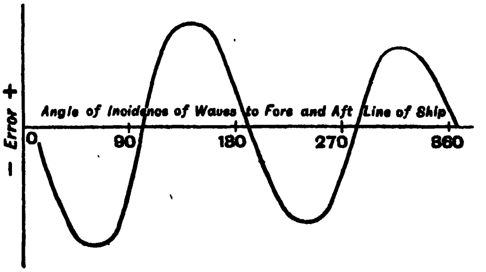

FIG. 6.
Typical Quadrantal Error Curve.

There are two commercial companies in this country which instal direction finding apparatus on ships, and up to date about 200 ships have been fitted. Photographs are shown, illustrating a typical installation of the Marconi-Bellini-Tosi system, and an installation of the Radio Communication Company's Robinson system. Excellent results have been obtained with direction finding equipment on board ships, and as time goes on, and as more and more experience is obtained by the navigators, results will be very much better, and equipment of this nature will become a standard installation for all ships.

A special but very important use of direction finders on ships is in cases such as the recent sinking of the "Trevessa." With direction finders on ships, and with simple transmitting apparatus in lifeboats in mid-ocean, searching ships can be directed straight to the lifeboats.

INSTALLATION ON AIRCRAFT.

On aircraft there are two methods of installing direction finding apparatus. The system most generally used is the Robinson system. In this case the coils are usually fixed into the wings, the main coil being placed in the fore and aft direction, and the auxiliary coil athwart-ships. The whole aeroplane is rotated in order to determine a bearing. This system is capable of being used by pilots themselves, and is particularly applicable to cases where definite routes are to be flown. For commercial flying, say, from London to Paris, or London to Amsterdam, with transmitting stations at both ends, the aeroplane can be flown continuously in the direction of its destination in each case. The operation is quite easy for the pilot, and after a little experience pilots get great confidence in this method. A test of the method was made sometime ago by having a ship transmitting at sea out of sight of land. An aeroplane started from Biggin Hill in Kent without any information, except that it had to find the ship which would transmit a particular signal every few minutes. The ship might have been in the English Channel or in the North Sea, but the observer immediately on getting into the air at Biggin Hill gave the pilot the correct course, and the aeroplane was flown straight to the ship, which was some 10 to 15 miles south of Brighton. The course followed from Biggin Hill to the ship was not deviated from in any degree. It should be noted that in this particular case visibility was very bad, and the pilot was within two miles of the ship before he observed it.

Rotating coils are sometimes fitted in aircraft, and one typical fitting is shown on the screen. In this case similar installation errors are obtained as in the case of ships, and it is necessary to determine these errors and to correct them or to allow for them. A typical flight in which these coils were used was made under the command of General Brancker, the navigator being Lt.-Col. Towler. This particular flight was made from Biggin Hill to Paris. The beacon stations used were Poldhu, Horsea, Nauen, Paris and Chelmsford. Position was determined from time to time, and it is to be noted that the aeroplane was above the clouds for practically the whole of the flight, the clouds on this particular day being very heavy. On the return flight General Brancker gave his instructions to the navigator with a view to testing out the system thoroughly, the navigator having no idea as to the destination of the flight. He was told to make for various points from time to time. Fig. 8 shows the course indicated by wireless navigation, and the actual course followed by the aeroplane as checked by the observer, who was told to observe the ground whenever he could see it. As a matter of fact he seldom saw the ground at all. It is to be noted that the navigator on this flight foretold the time of arrival at Paris and at Brighton to an exceptional degree of accuracy.

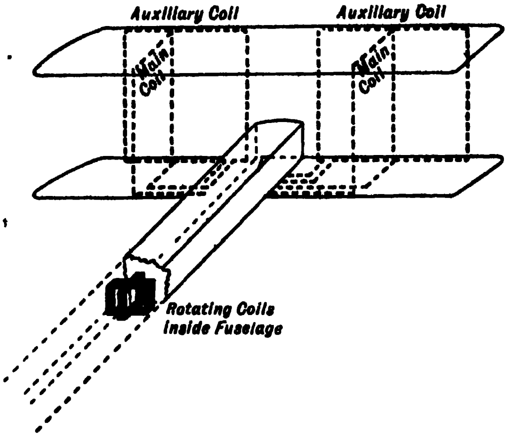

FIG. 7.
Method of fitting Fixed and Rotating Coils in an Aeroplane.

This system was also used by the American Naval Air Service when the N.C.4 was successful in crossing the Atlantic.

In this flight a particularly interesting example of the use of wireless direction-finding occurred shortly after the flying boat had left the Azores. The magnetic compass had become inoperative, with the result that the boat missed two of the ship stations placed for its guidance, and

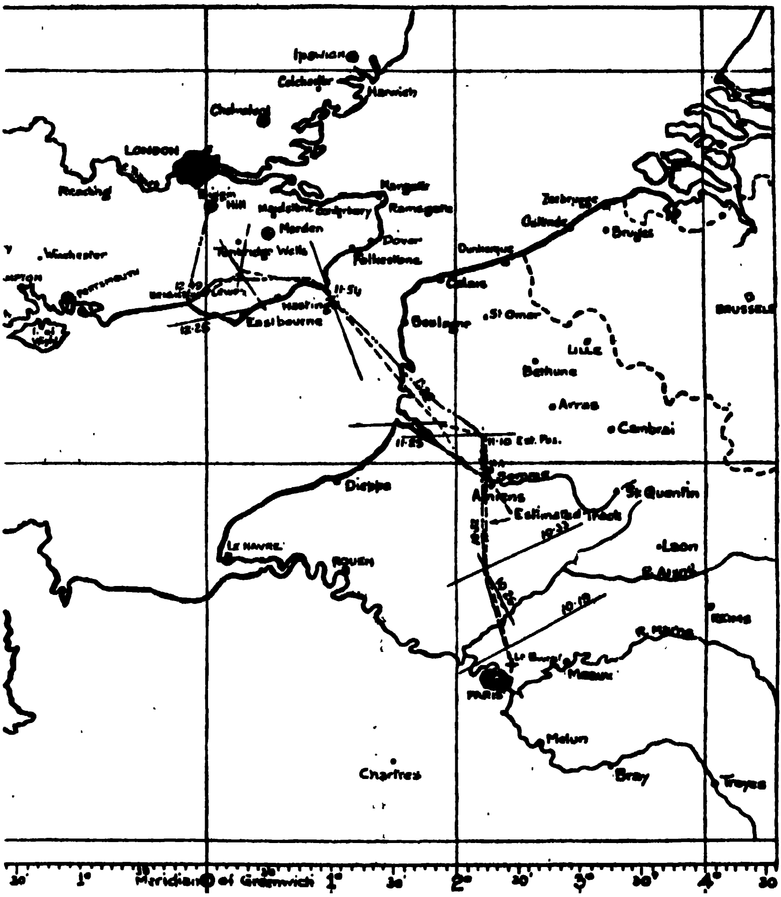

Fig. 8.

Flight above clouds from Paris to Brighton, using Wireless Navigation.

was in danger of becoming entirely lost. The direction of the next ship station was, however, obtained by the wireless direction finder, and by working on this direction the flying boat was enabled to proceed towards the ship and so regain its correct course.

ERRORS.

There has been considerable discussion from time to time as to whether bearings are subject to variable errors. It is established that under certain circumstance night errors are obtained, and these may reach considerable magnitude. These errors, fortunately, do not occur under all circumstances. A considerable amount of work has been carried out by the Radio Research Board in investigating these errors. The general conclusions which have been arrived at are that, outside the limit of accuracy of the instruments, where wireless waves travel completely over the sea, no errors occur either by night or day up to a distance of 100 miles. However, if waves have to travel for more than 15 or 20 miles over land, night errors are liable to occur. In cases where waves have hundreds of miles of land to traverse errors might be considerable. Recognising these facts, it is quite practicable to choose transmitting stations and general conditions so that bearings are reliable for navigational purposes.

The fact that the land has influence on bearings is borne out by a recent test made with aircraft. An aeroplane made a night flight between Croydon and Lympne. On the outward flight from Croydon to Lympne the aeroplane transmitted and asked for bearings. The ground direction finding stations found that there were considerable night variations of bearings and thus the position of the aircraft could not be given with any great accuracy. On the return journey, however, wing coils were used on the aeroplane, and the pilot determined his own direction on Croydon transmitting station, this station using continuous wave transmission. No trace of night error was observed, and the pilot flew a straight course from Lympne to Croydon.

DIRECTIONAL TRANSMISSION.

Another method for effecting wireless navigation is the reverse of the preceding methods. This consists in transmitting directional signals from the shore or ground, and employing ordinary receiving apparatus on the ship or aircraft. The difference between such methods and those already described can be readily seen by an analogy with lighthouses. In one case bearings of a lighthouse can be taken by having the light shining equally in all directions, and the directional observation made by eye and compass on the ship. In the other case the light is actually directed in the form of a beam and is rotated uniformly. Work of this nature is of comparatively recent practical development. Two methods have been proposed.

WIRELESS BEAM.

It has been found possible to concentrate wireless energy more or less in one direction by the use of reflectors or mirrors of a particular nature. This is only possible if the wavelength used is much shorter than ordinary commercial wavelengths. Marconi and Franklin have developed a system which makes use of wavelengths of the order of 6 to 10 metres. The aerial for this purpose is very small, consisting merely of a short unearthed wire with the transmitter inserted at the centre. This is placed vertically and is at the focus of a parabola. Around the surface of the parabola a number of vertical wires are placed, each wire being tuned to the same wavelength as the transmitting aerial. In this case the energy is reflected and concentrated into the form of a beam. A perfect beam such as is known in optics is not obtained for the reason that the wavelength is long compared with the dimensions of the mirror. The distribution of energy is shown in Fig. 9, from which it will be seen that along the axis of the mirror the largest percentage of the energy is concentrated. Behind the mirror an inappreciable amount of energy is transmitted. By the use of such a beam it is possible to obtain a navigational method. The whole transmitting system with its reflector is rotated uniformly once every two minutes. A distant observer will hear the signals only when the beam is pointing towards him or very nearly pointing towards him. The system is so arranged that a definite signal is transmitted on every point of the compass, and special marking signals between the points of the compass. Special cards are supplied for use with the signals, and it is only necessary for the observer on the ship to record the signals heard and to refer to this card for him to know from which point of the compass the signals are obtained, and thus his bearing is obtained directly. This method is installed

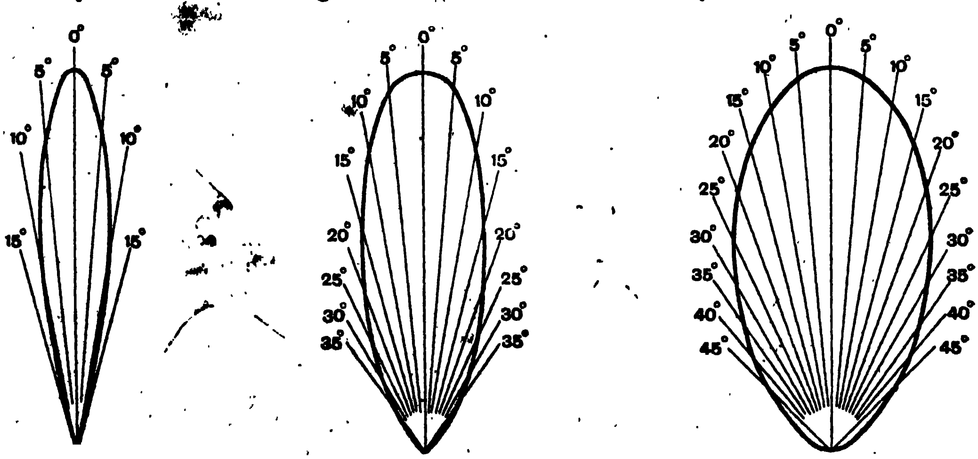

FIG. 9.
Polar Curves for Marconi Beam.

at Inchkeith in the Firth of Forth and has given satisfactory working. It has up to date not given very great range, the working range being about 10 miles.

This method has obvious advantages over the preceding methods. The principal advantage is that the technical work is concentrated at one spot and the observation of bearings can be done by unskilled personnel. It should be pointed out, however, that a special receiver for short wave reception is essential on the ships.

ROTATING LOOP METHOD.

Suppose that a loop is used as a transmitter, the reverse effects of reception are obtained. It is found that maximum signals are transmitted in the plane of the loop and zero signals at right angles to the loop. By rotating a loop of this nature uniformly, say once in 60 seconds, a distant observer will hear maxima and minima of the signal. Suppose further that a distinctive signal is transmitted when the plane of the loop is due north and south, and that a distant observer knows the time of rotation of the loop. If he can obtain the time of rotation from the north and south position to the position where he obtains maximum signals, or preferably minimum signals, he knows at once his bearing from the loop. For instance, suppose that the interval from the distinctive signal to the time of his maximum signal is 10 seconds, and that the time of rotation of the loop is 60 seconds, then his bearing is 10-60ths of 360°, *i.e.*, 60°.

This method has only been developed recently, and at first sight it would seem as if the range obtained would be very small as loops are supposed to be inefficient radiators. It is known that the amount of energy transmitted from a loop compared with that transmitted from an open aerial is small for the same aerial current. However, considerable assistance is obtained from the fact that it is possible from the same primary power to obtain much greater aerial currents in a loop than in an open aerial, and thus the contrast in ranges between loops and open aerials is not so bad as it would seem at first sight. This contrast is made more favourable for the loop by using shorter wavelengths. Loops have been developed for this purpose by the Wireless Department of the Royal Aircraft Establishment. A photograph of a loop is shown in Fig. 10. The loop is square of 5ft. side, and consists of six turns. Continuous wave or interrupted C.W. transmission is employed. With a power of 500 watts it is possible on a wavelength of 500 metres to put 40 amperes into this loop, and this has given ranges, to an aerial on the ground, of 50 miles without the maximum having been obtained. Under much more strenuous conditions, *i.e.*, to aeroplanes, signals have been heard from this loop to a distance of

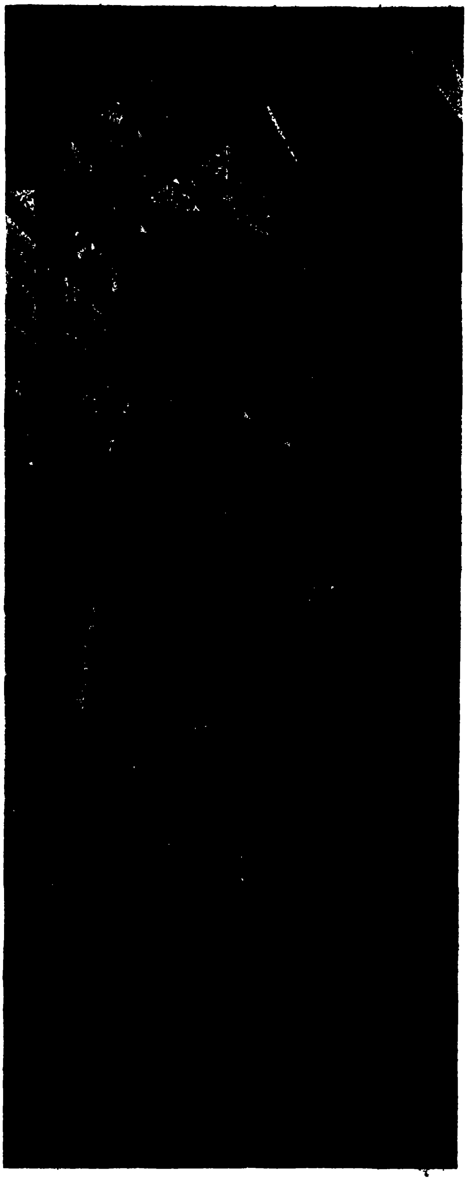

FIG. 10.

Rotating Loop Directional Transmitter.

30 miles, so that this method of directional transmission appears exceedingly hopeful. Using crystal reception with an ordinary ship's aerial, it is estimated that under these conditions a distance of 12 miles can be obtained, but without much trouble it will be possible to use powers of 5 kilowatts and the range should increase sufficiently to be useful to crystal receivers up to a distance of 50 miles. It should be noted that it is quite possible to do this with ordinary commercial wavelengths, so that on a ship the ordinary wireless receiving apparatus can be used and all that a navigator requires in addition is an accurate stop-watch.

CONCLUSION.

Various methods for determining bearings have been described and examples of the use of these various methods have been given. Sufficient has been said to indicate that it is an absolute certainty that the era of wireless navigation is not far distant. Progress is rapid, difficulties are being overcome, and knowledge is sufficient at present to warrant universal adoption. Means for the dissemination of this knowledge is desired so that it may be brought within reach of every navigator.

All methods of wireless navigation have their uses. The tendency will be for the shore direction finding system to continue its use and probably to extend. However, the advantages of direction finders on ships and aircraft are so great that this method will ultimately be of more universal application. Directional transmission beacons on shore will also have great application, and in the future this method will have parallel use with that of the direction finders in the ships and aircraft.

In this country development work is being carried on by the Government, research work is being carried on by the Radio Research Board, and the application and some development is being carried on by various commercial companies. It is a big subject and involves considerable expense, and all credit is due to commercial companies for carrying on this development with, up to the present time, very little, if any, financial profit. There is need for great support by all Shipping Companies, the Board of Trade, Trinity House and Lloyds, so that at the earliest possible moment accidents at sea and in the air shall be minimised, and that there will be fewer cases heard of ships lost without trace.

DISCUSSION.

THE CHAIRMAN (ADMIRAL SIR HENRY JACKSON) said that the author had touched on the past, present, and future directional wireless as applied to navigation and other purposes. He had described the rapid development of the apparatus necessary for this work, particularly in this country during the stress of war, and he indicated that this country held a leading part at the end of the war. Apparently that had not been maintained, at any rate so far as maritime purposes were concerned—he thought it had been maintained so far as the Air Force was concerned—and at sea it had not been made use of to the extent to which many of them had hoped. He agreed with the author, but he was a little more sanguine with regard to the future. He had had a great many conversations with and requests from port authorities and shipping people, and others connected with navigation, concerning the reliability and accuracy of the apparatus. His reply was always the same. It was to the effect that direction finding by wireless could be relied upon to give accuracy within two degrees up to about 100 miles by day or night over sea, provided that the stations had been tested and if necessary corrected and calibrated before being brought into use. This was based on nearly four years' work carried out systematically by the Radio Research Board. The observation work had been carried out with the three types the author had described, on board ship, oversea, and overland, with waves varying in length from those used by the powerful commercial stations down to the shorter waves used mostly at sea. Under favourable conditions for good accuracy—namely, skilled observers, absolutely unbiassed in every respect as to the results obtained, well constructed apparatus carefully tested for errors, quiet surroundings, and frequent readings of the same transmitting station—the accuracy obtained was not necessarily greater than that obtained in the Battle of Jutland eight years ago. He repeated that the accuracy now was not greater than it was at the Battle of Jutland. The day before that action, in daylight, a change in the bearing of a German battleship, distant 300 miles, of 1½ deg. in two consecutive observations about one hour apart, convinced him that the German high sea fleet was on the move, and decided him to send out the British Grand Fleet to sea with all dispatch. This resulted in the Battle of Jutland. A change of 1½ deg. was enough. That was eight years ago. Had he been faced with the making of such a decision four years ago he would have hesitated. During those four years many reports indicated that these wireless observations were liable to inexplicable variations, especially at night. These had been described by the author and investigated by the Radio Research Board, and they were now in a position to say where and up to what distance such errors did not make their appearance—that is to say, up to 100 miles at sea, day or night. Although they could not yet foretell their magnitude or assign their cause, the work was still proceeding hopefully, and some results were being gradually arrived at which might not be altogether hypothetical.

Well, it seemed to him highly probable that the wide circulation of the reports of the variation observed in direction-finding bearings during the last eight years had been one of the reasons why the mercantile marine had been so chary of adopting expensive apparatus on a large scale, and that they were only awaiting refutation by reliable authority of this reputed liability to error. The author had done much to show that this was a libel so far as work at sea was concerned, and also work in the air, and the speaker hoped that his work would bear fruit shortly. There were probably few localities in the world in which direction-finding navigation would be more useful than around the British Isles. The fact that airmen, without any exception, welcomed the aid of wireless was not surprising to the speaker. He was not an airman, but an old sailor, and he had served in sailing ships without steam and navigated them. He had served in such vessels in the Bay of Biscay in the winter, with no chance of observations for a week. In such circumstances the position got less reliable every day, and the sailor knew less and less where he was. Even then they were not so badly off as the airmen, because they did know the direction of the winds, thanks to their compass, whereas if the airman was above the clouds even this might not be known to him. Under such circumstances to pick up a wireless beacon might well be regarded as a gift from the gods. One of the reasons possibly why sailors had regarded this gift from the gods as a gift horse whose mouth they might well inspect, was due to the higher speed of present-day navigation, better means available for its accurate measurement, better charts and surveys, better tidal information, more efficient instruments of various kinds, and so forth. One of the things which might be acceptable was this radiating beacon, which certainly had, he hoped, a great future before it. It enabled the sailor to fix his position without having to instal other apparatus than that which he was obliged by law to carry. The speaker hoped to live to see a great many of these installed, especially in estuaries. It rested with the shipowners to decide which type of apparatus they would have. They could instal the Bellini-Tosi or Robinson systems if they liked to do so, only if they did so they ought to be rather careful, in taking the bearings of stations, not to use those too far inland, especially at night; or they might bring pressure to bear upon the Board of Trade to erect more wireless stations for directional finding work around the coasts. In New York Harbour, as the audience had seen, there were twenty stations or thereabouts for the one harbour, whereas in this country we had about half-a-dozen around the entire coast. Certainly we were not so far ahead as the Americans. It rested on the shipowners to press for further improvements. If these were not forthcoming they must utilise one of the systems of observation upon their own ships. He would conclude his remarks by congratulating the author very much upon his paper.

Colonel Lyster F. Blandy, D.S.O. (Air Ministry) congratulated the author upon a very clear and interesting paper. This was a most attractive subject, and perhaps the speaker was one of the first people to benefit by it. He had shared in one of the air trips which the author had described that evening. They went up on a very "dirty" day and got above the clouds. There it was beautiful sunshine. They went with great confidence, thanks to their wireless. The author had been working on this subject for a long time, and it was owing to his work that they were so confident on the occasion described. The work he had now put in on the radio-beacon was very valuable. In particular the speaker could appreciate its enormous value to the Air Force and in commercial aviation He felt that this matter was in very good hands.

Major B. Binyon (Radio Communication Co., Ltd.) joined with Colonel Blandy in congratulating the author on the very admirable manner in which he had dealt with the subject. It was a difficult subject to explain, and he had explained it in a most lucid manner. It was the speaker's good fortune to see some of Dr. Robinson's very early work in the development of this system, and to fly in machines fitted with his directional system. He was interested to learn that the early work with which they commenced experiments—namely, the fitting of wing coils—was one which he to-day believed would be of the greatest value in the directional guidance of aeroplanes on point-to-point flights. The author mentioned in his paper that aeroplanes fitted with wing coils would fly directly to the transmitting station, but the speaker thought he should mention that if there was very much drift that, of course, might not be actually the case. They might approach the distant station in a curved course. But, as a matter of fact in practice the operator, in taking frequent observations on the distant station, learned not to fly with his signal balanced—that is to say, with his two signals equal—but, learning what his drift was, he flew with the signal on one side slightly louder than the other. So he was able to steer, with a little experience, a perfectly straight course to the distant station. Since the war it had been his own good fortune to see much of the work of installation of Dr. Robinson's system on board ship. There were perhaps two principal difficulties to be faced One difficulty related to personnel, and the prejudice which seemed to exist against any innovation on the recognised system of navigation. Unfortunately, one often got criticism which he was afraid was both unscientific and quite unjustifiable. Nevertheless, in spite of the prejudice which had been shown against the introduction of direction-finding it had made very great progress, particularly recently. There were, of course, other difficulties. One which the author had not mentioned was the particular characteristics of the ships themselves. On a large passenger vessel one had all kinds of electric disturbances to contend with. Some passenger vessels were fitted with an alternating buzzer to the cabin bells, which was liable to act as a radio-transmitter, and to cause an extraordinary amount of disturbance. On a big passenger vessel there were large numbers of fan motors on the upper deck working ventilating shafts, and these might have bad or defective commutators on which sparking occurred; these, again, were capable of producing considerable inductive noises. There were recognised methods of dealing with these things, but often the ship's electricians took exception to having condensers and the like fitted across their commutators to eliminate disturbing noises. The use of an electrostatic screen whcih was placed over the coil itself has been introduced by the Radio-Communication Co., and had helped very much in reducing the quadrantal errors which might be experienced from the rigging of the ship.

The position in which the direction finder was installed was another very important matter. They could only proceed on general rules, but it should be always installed for preference in the fore-and-aft line of the ship, and as far as possible should be symmetrical in relation to the funnels and other rigging, and away from large masses of asymmetrical metal, such as a large iron railing or a big water tank or anything of that sort. The author mentioned the automatic elimination of quadrantal error. This was a perfectly practicable proposition, but actually the speaker doubted whether there was very much to be gained by it. The author had shown a curve of the quadrantal error which was approximately a sine curve, but the speaker had never actually, among the many quadrantal curves on ships, seen one which was absolutely a true sine curve, and in any automatic balancing system which one might apply to the elimination of quadrantal error it was usually only the true sine curve which could be dealt with, and, therefore, there was always left some additional small error which had to be corrected for from a chart or table, and if one was going to use such a table at all, in his opinion the total quadrantal error might as well be applied from that table without troubling to apply merely a portion of it.

In connection with the beacons which the author had described, the speaker had a great belief that they would prove very valuable, particularly the system upon which the author himself had been working, in view of the fact that it did not require any special equipment on board the ship. On the other hand, they should not lose sight of the fact that some of the most important work of the ship's direction-finding lay in the ability of one ship to take a bearing upon another, and he would be very sorry to see the rapid development of a beacon tending to prevent the shipowner from himself installing a direction-finder on board ship, for the reason that the maximum safety of life at sea was not obtained unless a ship could also take a bearing upon another ship at sea, which necessitated installing a direction finder on board. In conclusion, he wished to pay a tribute to the admirable work which had been done under the Chairman's guidance by the Radio Research Board, and which had gone so far to prove the great value of wireless as an accurate method of direction-finding.

COMMANDER J. A. SLEE (Marconi Company) added his congratulations on an extremely interesting paper; the explanations given in the paper were extraordinarily lucid. He went on to refer to life-saving at sea. Nowadays a ship did not get into distress until after prolonged bad weather, when probably there had been no chance of making observations on the ship for some time, and, therefore, her position was likely to be quite wrong. There was one case which was of quite spectacular interest. A ship gave a position about 90 miles wrong; her position was picked up by a direction-finder on another ship; a boat was sent, which reached the ship when it was in a sinking condition, and the ship actually sunk before the rescue boat regained its own ship. Direction-finders on shore could not help in such cases, because they happened at sea, nowhere near the coast. That was one of the great arguments for direction-finders on ships. He thought he was not far wrong in saying that for most of the ships of the mercantile marine the figures were roughly as follows: Of British ships which carried wireless (about 3,000, that is, about half the mercantile marine of the world), 130 to 140 British ships carried direction-finders. (He was speaking of merchant ships only.) Of the ships of other nationalities which carried direction-finders, there were just over 40 American, just over 50 French, just about 40 Italian, so that the total number almost bore out the proportion of British ships to other ships—there were 3,000 British ships, and, roughly speaking, 3,000 ships of other nationalities, and about 130 ships of the British mercantile marine carried direction-finders, and about an equal number of ships under the flags of other nations did the same. Another thing was the use of wireless transmitting stations on land for direction-finding purposes. Trouble here arose if a point of land jutted out between the transmitting station and the ship. This generally caused an error, which reduced the accuracy of the bearings from first-class (within two degrees) to second class (within five degrees). The existing wireless stations were never built to serve as d.f. beacons, they were built for telegraphic communication, and a great many of them had their usefulness for direction-finding purposes rather curtailed by the land around them. There was pressing need for special stations erected expressly for the purpose of serving as beacons for d.f. work, and some experimental stations were already in existence in this country. Facts and figures were being compared, and good work begun.

Mr. J. Herbert Scrutton (Chairman of Lloyd's Register) said he had no right to intervene in the discussion, because he was not a scientific man at all, and the only right he had to say anything was due to the fact that he made a voyage within the last month or so in a ship that had a direction-finder. The weather was extremely kind in the respect that it gave full opportunity for the most practical testing of the instrument. He came up from Gibraltar in one of the Orient boats, and they passed Cape St. Vincent the first night, Finisterre the second night, and Ushant the third night. No observation was obtained on the voyage, but they made the Eddystone right ahead. He overheard one of the crew say to another, "Nobody in the world but our old man could have done that." Personally he had not any doubt that it was the direction-finder which should have received the compliment. Of course, the captain had his soundings, he got his dead reckoning, he got the broad angle of which the author had spoken, and he got his position with practical certainty. But the fact was that these ships, apart from the direction-finder, very often did not know where they were. Admiral Sims, when the American Fleet was over here, had the remark made to him, "I see an American battleship got lost in the North Sea." "Yes," he replied, "whenever they go out they get lost." Looking at the losses which did occur, it was obvious that unless the captain had the opportunity of taking sights in the ordinary way he was very soon out of his position, and quite far enough to put him into trouble. As a ship-owner the direction-finder struck him as the most extraordinary advance that he had ever seen in his experience. With this aid a man coming towards the land in a fog was able to fix his position within a mile or two. They could hardly imagine the relief this must be to the navigator. Any who had stood on the bridge of a big steamer was aware of its atmosphere of anxiety, and the direction-finder was of the most wonderful assistance, used intelligently, and in combination with all the other aids to navigation. Of course, shipping authorities were not very willing to take up a new thing. Losses at sea were now few and far between. Moreover, shipowners were not very prosperous at present, and the natural British conservatism also operated. The speaker was "all out" for putting the direction-finders on board the ship instead of the ships taking the bearings given by the shore stations. The trouble with wireless would be that there was too much talking. If the instrument could be used without adding to the disturbances already existing, it would be very great thing. In the wireless cabin they had A, B, and C all talking at once. The operator, of course, was able to distinguish, but manifestly, with the number of ships engaged in overseas trade, if one could get this effect without making any further disturbance it would be of enormous advantage.

General Sir William S. Brancker, K.C.B. (Air Ministry) sent a letter, which was read by Colonel Blandy. After expressing his regret at being unable to attend Dr. Robinson's lecture, he wrote:

> "As long ago as 1917, as a member of the first Civil Air Transport Committee which was convened that year, I ventured to say that I considered wireless communication to be the life-blood of air navigation. I have [illegible] cause to alter that opinion; useful and reliable as the compass is, it cannot solve the problems of navigation above the clouds, and it is above the clouds that most aerial navigation will take place in the future.
>
> "Personally, I favour what I have sometimes described as the 'lighthouse' system for the future—that is, the provision of a system of wireless stations on the ground which will emit periodic distinctive signals for the benefit of all aircraft in the air, the calculations and plotting necessary being carried out by the crew of the aircraft; even with a crew limited to pilot and navigator this should be possible, with improved apparatus and a little more room and comfort in the cockpit than are provided in existing aircraft. Air navigation across the Channel has already been revolutionised by the provision of wireless telephony, and this is only the beginning of things!
>
> "I congratulate Dr. Robinson on his paper, which I have read with very great interest."

M. Pierre Schilowsky (President de la Société Gyroscopique et de Mécanique scientifique) pleaded that in further practical improvements with regard to aviation the psychology of the pilot should be borne in mind, more particularly in the direction of arriving at some method of visual radio-telegraphy, such as the wireless compass. The great embarrassment of the pilot in a fog was his total inability to use his visual perception in regard to the instruments by which he steered his course. He pleaded that the brains of the technicians should be directed to elaborating some instruments of visual wireless. He admitted that the question was full of difficulties.

Captain Colin Nicholson, R.D., R.N.R. (Branch Secretary, Mercantile Marine Service Association), felt sure that most of those present knew more of the subject under discussion than he did; but as a navigator of the old school, he would like to say how much the lecture of Dr. Robinson had appealed to him.

Mr. Scrutton had referred to a recent trip of his, where it was alleged that a good landfall had been made in an Orient liner, which he (Mr. Scrutton) had no doubt should be ascribed to the wireless bearings received by the Commander. Being an ex-Commander in that Line himself, and having "made" the Eddystone many times under both good and bad conditions, he could bring forward an illustration. Some years ago, being at that time in command of an Orient steamer, a pilot was picked up off Plymouth after a bad trip across the Bay. The pilot's first information was that a large steamer was ashore—the s.s. "Suevic";—followed quickly by the remark that there was also another one ashore—the s.s. "Jebba." By good luck, or, perhaps he might be permitted to say, by good navigation, the Orient steamer was afloat, and duly arrived at Plymouth. Now, had the captains of those two steamers been able to ascertain their position by wireless directional bearings, the probability is that there would have been two casualties less in Lloyd's List the following day.

The best navigators would be the first to adopt any aid to safe navigation: and as the transmission of wireless directional bearings became less and less liable to error—Dr. Robinson had shown how small such errors now were—so navigators would make confident use of them.

Looking round at the wonderful advances recently made, and yet going on, it was one of the speaker's regrets that, having practically ended his sea career, he could not participate in the facilities now being introduced and perfected. His Society, the Mercantile Marine Service Association, had from the first kept a watchful eye on developments, and had, in fact, for some time been urging the authorities to establish more Wireless Direction-Finding Stations round the coast of the United Kingdom.

In conclusion, he thanked the lecturer for his very instructive lecture and interesting illustrative experiments.

Captain Barnard spoke from the point of view of the airman in the commercial air service. If the airman flew below the clouds he was in some danger, and with low-lying clouds the danger was obviously greater; if above the clouds he was more or less safe. In commercial aircraft they had all sorts of things laid down that they had to do by wireless, to report their positions, to get weather reports, and so on, and in order to get this information they had to listen in on a distant wavelength, but it was not practicable for them to obtain all this information on one aerial and to listen in to all sorts of buzzers on another aerial. In commercial aviation they had to utilize wireless to the same extent as they utilized machines and engines, they all went together to make one more or less efficient whole. He was afraid that until such time as they could have machines carrying about fifty passengers, with crew in proportion, it was not possible to go in for these idealistic schemes. They must get on with it as best they could.

Captain F. Tymms (Air Ministry) spoke of the degree of accuracy possible in wireless navigation from the point of view of detecting changes in the wind. An error of one degree in a bearing, at a range of 1,000 miles, would result in an error in position of something like two miles. To detect a change in wind one had to calculate the wind from two observations of position. If both these observations were incorrect by two miles—and the navigator had to suppose that such error might exist—and the errors were not in the same direction, the total error might be as much as four miles. This error occurred in a time interval of 10 to 15 minutes—consequently the error in the wind determination might be in the neighbourhood of 20 miles an hour. Although the present results were of great value, therefore, he thought it very desirable for aerial navigation that the wireless experts should still strive for greater accuracy. With regard to directional transmission he wished to emphasise the advantage gained by the elimination of quadrantal error and compass error to which the author had alluded. Compass error on some machines was still a serious factor.

Lieut.-Colonel H. F. Towler said that from his own experience with regard to the standard of accuracy given by a ships' company for visual bearings, he thought there could be no doubt that the accuracy of direction finding was quite good enough for ordinary sea navigation if applied with intelligence.

The Chairman, in calling upon the author to reply, said that he did not wish his remarks to be misunderstood—he had nothing to say whatever against putting in direction-finders on board ship.

Dr. Robinson, in reply, said that his paper had escaped with very slight criticism, but the discussion had shown that interest in wireless navigation was increasing, and that was the object of his paper. He was much interested in the facts regarding marine navigation which had been brought forward. He had intended to give himself quite a number of such facts, but everything could not be included within the compass of a paper. With regard to M. Schilowsky's suggestion about visual radio-telegraphy, this was a question which not merely the speaker but everyone who had considered wireless telegraphy had thought about. Undoubtedly in the future one would get on towards visual radio-goniometry—in other words, the actual wireless compass. But there was a long way to go, a large number of wireless problems had yet to be solved before that point was reached. He thought that wireless telegraphy would go a great deal further once certain conditions in actual wireless technique had been satisfied. The application to the wireless compass would at some time in the future be easy, and the settlement of that problem would settle a number of other large problems in wireless.

The other point which required some attention was with regard to wing coils. Captain Barnard was under a misapprehension if he assumed that there was any reason at all why he should not also use wing coils for normal reception. His experience had been the experience of all pilots ever since aviation began. The object of the people who designed gadgets was to make them as simple as possible. His own deduction as to these coils was made purely with the object of assisting pilots, and they did appear to be the very best thing for pilots' use. The question which Captain Tymms had brought forward bore on the same subject. He had touched upon one of the greatest problems which had to be solved; the speaker would like to solve it, it had not been solved up to the present. On this matter of landing in fogs, accuracy was not sufficient, and quite a number of ideas were in being for further assisting the pilot, but that was about as far as they could go at the present time. He wished to add how honoured he felt that Sir Henry Jackson had taken the chair at that meeting.

The Chairman said that it was a great pleasure to support Dr. Robinson in view of the long-continued support which Dr. Robinson had given him on the Radio Research Board. He asked the audience to express its thanks to Dr. Robinson for a very interesting paper.

The vote of thanks was accorded unanimously, and the proceedings terminated.

Lieut.-Colonel H. F. Towler writes as follows: I understand Captain Tymms to say that an error in position, due to a 1° error in bearing at 100 miles, of say 2 miles, may in certain circumstances cause the navigator to calculate a wind some 20 miles in error.

These circumstances must be allowing for a run of only six minutes between the two fixes from which the calculation is made.

Similarly, if it were possible to allow a run of only three minutes between fixes an error of 40 miles in the wind could be created.

This latter case is obviously ludicrous. Obviously every form of navigation is striving for increased accuracy, but in the present state of the science an error of two miles would frequently occur in most of the older and well recognised forms.

It is, therefore, necessary that in any form of "chart work" the navigator should recognise the necessity for allowing a reasonably long run between observations to avoid creating artificial errors.

The principal object of the navigator is to take his ship or aeroplane to her destination; if he bases his alterations of course on observations half-an hour apart, and experiences the maximum error o-f two miles in the fix, his error in the next hour's run would be between four and eight miles only. In practice he would take further observations, and any accumulation of error would, therefore, be avoided. It is wiser to avoid the habit of regarding the aerial navigator's principal duty as that of determining the force and direction of the wind. The wind *can* be determined from a series of observations plotted in the course of a long flight. But the first requirement is to plot a series of fixes on the chart which enable the required track to be followed as closely as possible.

OBITUARY.

Sir Frederick William Duke, G.C.I.E., K.C.S.I.—Sir William Duke, Permanent Under-Secretary of State for India, who died very suddenly on the 11th June, in his 61st year, had been a Fellow of the Royal Society of Arts since 1915. He always took a keen interest in the Society's work, had been a member of the Committee of the Indian Section since 1915, and was Chairman of that Committee and a member of the Council from 1916 to 1920. Both in the Committee and in the Council his experience, his wide general knowledge, and his fertility of suggestion were of great value and his relinquishment of the Chairmanship, which was necessitated by the pressure of official duties, was sincerely regretted by his colleagues.

Sir William Duke was the son of the Rev. William Duke, D.D., Minister of the Parish Church of St. Vigeans, Forfarshire. Educated at Arbroath High School, University College, London, and "Wren's" he passed the open competition for the Indian Civil Service in 1882 and two years later was posted to Bengal, in which province the whole of his career in India was passed. He never coveted the limelight of high office and, though his admirable work as a District Officer and subsequently as a Commissioner was fully realised locally, it was not till 1908 that the then Lieutenant-Governor, Sir Edward Baker, selected him as his Chief Secretary. In 1910, an Executive Council was created in Bengal and Duke became one of its members. In the following year he acted as Lieutenant-Governor in the absence on leave of Sir Edward Baker and when, six months later, Sir Edward retired without returning to India, Duke remained at the head of the province till Bengal was made a Governorship. He then became the Senior Member of Lord Carmichaels Council. In 1914 he was appointed a Member of the Council of India. and in that capacity, in 1917, he accompanied the Secretary of State, Mr. Montagu, to India There, and afterwards in England, he took a leading part in the discussions which ended in the framing of the Montagu-Chelmsford Report and the passing of the Government of India Act of 1919 by which the existing constitution of British India was established. At the end of 1919 he succeeded Sir Thomas Holderness as Permanent Under-Secretary of State. The duties of this post during the introduction of the new arrangement have been exceptionally arduous and Duke till his death devoted to them his talents, his industry, his calm and sympathetic judgment, and his remarkable power of overcoming difficulties with a sympathetic and unfailing courtesy which secured for him the highest appreciation. The work of his later years was recognised officially by the conferment on him of the C.S.I. in 1910, the K.C.I.E. in 1911, the K.C.S.I. in 1915, and the G.C.I.E. in 1918, and personally by the regard and affection of all who had the privilege of working with him. He obtained the high honour of election in 1922 to the Athenæum Club under Rule ii. Sir William Duke was a man of singularly unassuming character to whom distinction and popularity came unsought. In him, it is no exaggeration to say that an able and devoted public servant has been lost to India and a trusted and valued friend to all who knew him, whether in official or private life.

NOTES ON BOOKS.

Peasant Art in Switzerland. By Daniel Baud-Bovy. Translated into English by Arthur Palliser. London: "The Studio," Ltd.

This volume is the fifth of an excellent series on Peasant Art published by The Studio, the other four dealing with Sweden, Lapland and Iceland, with Austria-Hungary, Italy and Russia. The author has selected for description the Lötschenthal, a remote valley hidden in a fold of the Alps, the only means of access to which is a single mule track. The peasant art to be found here is very characteristic. After a brief introduction dealing with the nature and surroundings of the valley, and the artistic instincts of the inhabitants, M. Baud-Bovy proceeds to discuss the various types of peasant's house, which he classifies as Celto-Roman, Italo-Roman, Rheto-Roman, "Plateau" house, and chalet. Some charming illustrations are given of the various types, showing characteristic features of both exteriors and interiors. This section is followed by a very interesting chapter on woodwork. Some of the illustrations here are admirable and show the Swiss peasant as a woodcarver of a very high order. Nor is the section on metalwork less interesting. The Swiss blacksmith and pewterer are very accomplished craftsmen, and one or two of the inn signs illustrated are beautiful and delicate pieces of ironwork.

Other sections deal with costumes, textiles, and pottery and glassware.

The illustrations, of which there are no fewer than 430, are admirably selected and reproduced, and they give a very adequate representation of the qualities of the peasant art of Switzerland.

CORRESPONDENCE.

LONDON TRAFFIC.

The paper on London traffic (reported in the *Journal* of May 16th) by Sir Lynden Macassey and the discussion which followed is most interesting.

There are means of expediting traffic that were not mentioned, one of which is the use of colour light signals, interlocking the complete area subject to congestion.

It is apparent that if traffic is timed properly, it is possible for two continuous streams to be operated over an intersection without cessation. However, the human element makes it next to impossible so to time it, and it is left for us to devise means by which we may approach the ideal. By the use of interlocked signals, the traffic is separated into "periods" which permits it to run a considerable distance without inteference, the time period being regulated according to the traffic density.

Another traffic question that is important and should be taken up, is the indiscriminate use of the red light.

We are trained from infancy that red is a symbol of danger and yet we find it used where no such indication is intended, for example, on fire escapes in public places, on stairs, exits, etc. The use of the red light on the rear of automobiles has been the cause of many accidents; the red light of a drawbridge having been sometimes taken for that of a standing auto. Minor obstructions on the road side guarded by a red light which can be passed with safety and an absolute obstruction across the highway, such as an excavation, are often indicated by the same red light. My thought is that the red light should be used only to indicate danger, stop, and stay, and that a caution signal (yellow) should be used on all such obstructions as may be passed, and of course, green to denote safety, clear, or proceed. This question is now being studied by the traffic organisations of the United States. The Railways on this side have standardised the use of these three colours.

AGRICULTURAL INDUSTRY OF PORTUGAL.

According to the Report on the trade, industries and economic conditions in Portugal, by H.M. Consul at Lisbon, agriculture is the basic industry of Portugal, occupying not less than 60 per cent. of the population. With a sunny but comparatively moist climate, the country is exceptionally fertile; almost the entire surface is capable of being utilised. More than a third is still awaiting exploitation, mainly for lack of transport facilities. In many districts produce cannot be distributed nor fertilisers supplied. It is estimated that 20,000 tons of additional fertilisers are required in the Alemtejo alone. An improved system of roads and railways, accompanied by extensive irrigation and the general adoption of modern farming methods, would easily increase the present results at least 100 per cent. As regards irrigation, a scheme exists for opening a canal from the river Sorraia, a tributary of the Tagus, which would irrigate 100,000 acres of the best land in the Alemtejo. The methods in use, except on some of the larger farms in the south, are reminiscent of the days when Portugal was a Roman province. Farming depends excessively on hand labour, of which there is a shortage. The conditions are aggravated in the frontier districts by the unfavourable comparison of escudo and peseta wages, a considerable number of labourers having crossed into Spain. At the same time, agricultural wages have more than kept pace with the depreciation of the escudo and the consequent increase in the cost of living. A farm hand who ten years ago would have been satisfied to earn 40 centavos a day now gets 10 escudos, equivalent to considerably more than the difference in the cost of living. Labour is, however, still cheap, and agriculture continues to be the chief source of national wealth. The most valuable crop is *wheat*, which is grown largely in the Alemtejo region above mentioned, once the "granary of the Roman Empire." The average yield of this crop is six to seven quarters an acre, but in some places nearly half a ton an acre has been obtained. The total wheat harvest averages 230,000 tons a year. Only once is it recorded to have supplied the whole of the national consumption, namely, in 1911, when it reached 322,000 tons. On that occasion there was a margin of 30,000 tons, but as a rule wheat is one of Portugal's largest imports. The yield in 1923 was one of the largest on record (approximately 453,994,820 litres), but owing to the disinclination of the farmer to adhere to official prices the Government authorized the importation of 50,000 tons of wheat in the interests of the public. As far as possible, it is the policy of the Government to encourage wheat growing. In some parts vineyards have been converted for this purpose.

Maize is produced in large quantities, all consumed in the country. The production in 1923 was 289,000 tons. Other cereals grown on an extensive scale include 130,000 tons of *rye* and 125,000 tons of *oats* and *barley*. About 200,000 tons of *potatoes* are produced, besides 60,000 tons of *beans* and 15,000 tons of *rice*. The latter is a declining product. Seed potatoes are imported from France and England in sailing vessels which return with fish and salt.

Much Portuguese fruit goes to England, especially *figs*, *almonds*, and *carob beans* from the Algarve, but the trade might be largely increased by proper cultivation. The annual value of the three crops named exceeds £500,000.

The *grapes* from which port wine is made are grown in the Douro Valley, though the brandy required to give it character comes from farther South between Santarem and Leiria. Table wines are produced over a wide area and exported to Brazil and the Portuguese Colonies and also to France. Attempts have been made to register the name Lisbon wine, but competing interests have thus far effectually opposed the movement. 100,000 hands are engaged in the vineyards. The vintage in 1923 was disappointing in the port region, being only moderate after holding out exceptional promise. Elsewhere the results were above the average.

Portugal follows Italy and Spain as the third *olive*-producing country in the world. Olive trees occupy an acreage exceeding three quarters of a million. The annual production is half a million hectolitres, valued at £1,500,000. Ten thousand presses are in use.

The yield of *cork* varies between 50,000 and 75,000 tons, valued at approximately £1,000,000. The area covered is about the same as the area under olive trees. There are nearly 100 cork factories, some of the most important being British.

The number of *livestock* is estimated at nearly 6,000,000, the same as the population. Sheep comprise more than half or just under 3,000,000; while the rest in order of number are pigs and goats—slightly under 1,000,000 each—cattle, donkeys, horses and mules.

Portugal being primarily an agricultural country, there is both a large actual demand and a still larger potential demand for agricultural machinery. This is a trade in which Great Britain has not recovered her pre-war position. The United States gets most of the orders for reapers and binders. Threshing machines are also bought chiefly from the States, though English threshers have not lost their good name. Germany has temporarily captured the market for motor ploughs with two cheap handy machines specially suited to the hard Portuguese soils, which require that in order to keep the nose of the ploughshare to the ground the main weight should be well forward.

In order to sell agricultural machinery in Portugal, it is necessary to make a study of the conditions of the soil and to demonstrate locally. By this method some 40 Holt caterpillar tractors have been sold—mostly in the south where the farms are largest. The average Portuguese farmer will not go out of his way to find the best machine—or any machine for the matter of that. He is content to go on in the old way. But if the merits of a machine are actually set before his eyes, he is always a potential buyer.

SOUTH AFRICAN OSTRICH FEATHER INDUSTRY.

The ostrich feather industry in South Africa dates from the year 1865, and during the course of the past 60 years has done much to enrich, and also to advertise, the country. However, an industry devoted to the production of an article of fashion is subject to great fluctuations, and consequently the industry has had many ups and downs. The market flourished during the late seventies and early eighties, so much so that in 1886 a shipment of ostriches was made from Cape Town to southern California, where the industry was first established in the United States. A serious depression occurred in feathers in the early nineties, but they revived in the later nineties. From 1905 the industry made great progress and reached its peak in 1913, when the value of ostrich feathers exported from South Africa was nearly £3,000,000.

Shortly after the commencement of the World War the industry suffered a depression from which it might have recovered if hostilities had not continued. Instead the trade steadily declined until 1918, when the value of feathers exported only reached about £80,000, less than it was 30 years earlier. A comparatively slight revival has taken place since 1918. The exportation of feathers in 1922 amounted to nearly £400,000, but this amount is far below the 1913 figure.

Owing to the fact that there are at present only 200,000 ostriches in the country, as compared with almost 1,000,000 in 1913, the industry is much handicapped. This tremendous decrease in the number of ostriches is attributable, writes the United States Vice-Consul at Port Elizabeth, to (1) deliberate slaughter of birds during the war because they were not worth their keep, (2) mortality through neglect, and (3) the stoppage of breeding. The decline in the ostrich-feather industry seems to be due principally to a change of fashion, but another reason given is the increased use of motor-cars, the wind from motoring having a very destructive effect on ostrich feathers It is hoped, however, that the more common use of closed cars will obviate this objection.

UNDEVELOPED NATURAL RESOURCES OF QUINTANA ROO (MEXICO).

A territory in Mexico possessing vast unexploited natural resources lies but 600 miles south of New Orleans. This 18,000 square miles of land is practically unknown and very sparsely populated. It extends nearly 300 miles from north to south and has a coast line of probably twice that length. It is known as the Territory of Quintana Roo and comprises the eastern part of the peninsula of Yucatan. The Government is territorial, the capital being Santa Cruz de Bravo (a town of about 2,500 residents midway down the Mexican Gulf coast); most of the remainder of the 9,000 people live in the villages of Payo Obispo, Cozumel and Bacalar.

Information as to the interior is scanty, and data obtained by the United States Consul at Progreso during a six-year residence on the peninsula has been secured chiefly from extractors of chicle gum, prospectors, and archæologists, the latter investigating the many ruins of once populous Maya cities. Reports are to the effect that, unlike other sections of the peninsula, Quintana Roo has several ranges of hills, about nine inland lakes, and a few short rivers flowing to the eastern coast.

The western portion is said to contain extensive green rolling pampas, the interior to be densely forested with valuable tropical woods, and the coast to abound in game and in food fish. The soil is claimed to be suitable for the production of maize, cotton, beans, coffee, indigo, rubber, sugar cane, tobacco, sweet potatoes, pepper, vanilla, henequen, tropical fruits, etc.

Modern transportation facilities are non-existent, but the advent recently of the first caterpillar tractor into the forests of Quintana Roo may initiate development of the resources of this reputedly rich and unexplored section.

RUBBER PRODUCTION OF ECUADOR.

Various trees, vines, shrubs, and herbs producing crude rubber, and indigenous to Ecuador, are found in a wide expanse of country at an elevation varying from 200 to 4,000 feet and with a mean temperature of 26° C. Such conditions exist in the Provinces of El Oro, Guayas, Esmeraldas; portions of Manabi, Los Rios, and Chimborazo; and the immense territory known as the Province of El Oriente, which is on the East side of the Andes at the headwaters of the Amazon River.

The tree producing most of the rubber in Ecuador writes the United States Consul-General at Guayaquil, is supposed to be the *Castilloa elastica,* which grows abundantly in its wild state; another form closely related to it is the *Tuna.* When 6 years of age the tree flowers during the months of November and December. A vine which eventually develops into a tree known locally as "matapalo" (*Ficus* sp.) also produces rubber, together with numerous other plants, including species of the genera *Apocynum* and *Brosimum,* yielding a milky juice which coagulates into a gum having the qualities of rubber.

There are a number of rubber plantations in the Balzar and Tenguel districts, as well as in the Provinces of Manabi and Esmeraldas, containing more than a million trees. These plantations are the result of a law passed in 1902 and amended in 1904, providing for a premium or bounty for each rubber tree planted in the Republic after that date, payable when the trees should attain an age of 5 years or more; however, no payments have ever been made.

The plants may be propagated from cuttings or seeds, the latter being the principal source. The method employed to start plantations is to cut out most of the forest trees, leaving a sufficient number for shade, and plant bananas in the open space. When the banana plants are a few feet high, the rubber plants are placed between them, which in six months are about 7 feet high and covered with large leaves, the growth being rapid..

The commercial grades of crude rubber known in Ecuador are : Andullo maroma and andullo duro (or hojas). Owing to the low price of rubber a few years ago its production ceased, as the returns were insufficient to cover the cost of gathering and marketing.

The Indians collect the latex and reduce it to crude rubber which is delivered to the exporting centres, whence it is shipped to foreign markets. The crude rubber is transported from the interior to the ports on the backs of men and mules or by canoe.

MEETING OF THE SOCIETY.

◆

INDIAN SECTION.

MONDAY, JUNE 30, at 4.30 o'clock.—J. C. FRENCH, I.C.S. "The Art of the Pal Empire in Bengal." THE RIGHT HON. THE EARL OF RONALDSHAY, G.C.S.I., G.C.I.E., will preside.

Journal of the Royal Society of Arts.

No. 3,736. VOL. LXXII.

FRIDAY, JUNE 27, 1924.

24 JUL 192

All communications for the Society should be addressed to the Secretary, John Street,

NOTICES.

NEXT WEEK.

MONDAY, JUNE 30th, at 4.30 o'clock. (Indian Section.) J. C. FRENCH, I.C.S., "The Art of the Pāl Empire in Bengal." THE RIGHT HON. THE EARL OF RONALDSHAY, G.C.S.I., G.C.I.E., will preside.

ANNUAL GENERAL MEETING.

WEDNESDAY, JUNE 25TH, 1924. LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair. The One-hundred-and-Seventieth Annual General Meeting of the Society was held for the purpose of receiving the Council's Report, and the Financial Statement for 1923, and also for the Election of Officers and new Fellows.

A full report of the Meeting will be published in the next issue of the *Journal.*

COUNCIL.

A meeting of the Council was held on Monday, June 16th. Present:—

Lord Askwith, K.C.B., K.C., D.C.L., in the Chair; Sir Charles S. Bayley, G.C.I.E., K.C.S.I.; Lord Blyth; Mr. A. Chaston Chapman, F.R.S.; Mr. Edward Dent, M.A.; Rear-Admiral James de Courcy Hamilton, M.V.O.; Sir Thomas Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.; Sir Herbert Jackson, K.B.E., F.R.S.; Major Sir Humphrey Leggett, D.S.O., R.E.; Sir Philip Magnus, Bt.; Mr. James Swinburne, F.R.S.; Mr. Alan A. Campbell Swinton, F.R.S.; Mr. Carmichael Thomas; Dr. J. Augustus Voelcker, M.A., Ph.D.; and Sir Frank Warner, K.B.E.; with Mr. G. K. Menzies, M.A. (Secretary of the Society) and Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

Preparation of the balloting list for the new Council was completed.

The Annual Report of the Council was considered, amended and approved.

The Financial Statement for 1923 was laid on the Table.

Preliminary consideration was given to the arrangements for Lectures and Papers in Session 1924-5.

Other formal business was transacted.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

MONDAY, JUNE 2nd, 1924.

THE RIGHT HON. VISCOUNT MILNER, K.G., G.C.B., G.C.M.G., in the Chair.

The paper read was:—

THE MANDATE SYSTEM AND THE BRITISH MANDATES.

By THE RT. HON. SIR FREDERICK LUGARD, G.C.M.G., C.B., D.S.O.,

British Member, Permanent Mandates Commission, League of Nations.

I welcome the opportunity afforded to me to-day to address you on the subject of the Mandatory principle and the British Mandates, for though the British Empire holds nine out of the fourteen Mandates, and has incurred responsibility for an additional million square miles, and some eight million people, less attention seems to have been devoted in this country to the theory and application of this novel experiment in International Law, and its present and future problems, than has been evoked in the United States, which holds no Mandate at all.

ORIGIN.

Let me first recall to your minds the conditions under which the system originated. The representatives of the victorious Allies, assembled in Paris in 1919, had to decide what was to be done with the former overseas possessions of Germany and Turkey. Many hundreds of millions of debt had been in-

curred in their conquest, and thousands of lives had been the price of victory in these outlying theatres of the Great War—especially in Palestine, Iraq, and East Africa. There is no doubt that on these grounds alone any idea of restitution to their former rulers would have been scouted by most—probably by all—as an insane proposal. Moreover, their misrule had been loudly denounced, and it was strongly felt that to expose to their vengeance the people who had espoused our cause in the War would be an act of unthinkable baseness. Yet it must be confessed with regret, that when the United States (which had never been at war with Turkey) refused the Mandate for Armenia, it was restored to that country. German writers, like Zimmermann in his "Mittel Europa," had indulged in visions of a great Black Army of well-trained African soldiers which should aid in world domination, and of ports in every sea which should serve as bases for submarines. Wireless installations like that in Togoland—one of the most powerful in the world—would ensure her communications with every base in time of war, and be a constant menace to the command of the seas.

On the other hand, President Wilson, who exercised great influence, not only as the representative of the United States, but as the only Head of a State present at the Conference, stood committed to the "Fourteen Points," which he had advocated as the only true basis of a just peace, and the Germans indeed maintained that the Armistice had in a general sense been based upon them. All the world at that time thought that the President spoke in the name of the United States, which would be a party to the treaty. He had enunciated the doctrine of "the Self-determination of small States," in spite of the protests, as we have since learned, of his Secretary of State, Mr. Lansing, who foresaw the false and impracticable visions it might create in ignorant communities. He had insisted, moreover, on the principle of "No Annexations," and indeed (as Mr. Quincy Wright points out in an American journal), the pre-Armistice agreement of November 5, 1918, had clearly repudiated annexation. Yet probably, the majority of the victors were in favour of this course, including France, Japan, and the three Dominions. Even General Smuts, who claims credit as an advocate of the Mandate principle, did not propose to extend it to the C Mandates. So strong indeed was the demand of the Dominions that they should acquire complete possession of the conquered territories contiguous to their own in S.W. Africa and the Pacific, that in the event it was with difficulty that a form of Mandate was devised, which General Smuts described as "annexation in all but the name,"—and American and Japanese writers have used the same terms.

How were these demands to be reconciled to the theories of "Self-determination" and "No Annexations," and to the secret treaties and understandings which had been made in the exigencies of the War, and to pre-Armistice protestations? The British public was deeply stirred by the accounts of German misrule and cruelty in Africa, and by Turkish massacres in Armenia, but British statesmen were not anxious to add new territories to the Empire, or to incur the vast expenditure which the assumption of responsibility for Palestine and Iraq would involve. The view of British statesmanship was (as we read in Mr. Page's "Life and Letters") emphatically expressed by Lord Balfour as early as May, 1917. "My firm opinion is," he said, "that the Colonies ought not to be returned to the Germans. The natives, the Africans especially, have been so barbarously treated, and so immorally, that it would be inhuman to permit the Germans to rule and degrade them further. But Heaven forbid that we should still further enlarge the British Empire! Besides, we should incur the criticism of fighting in order to get more territory, and that was not, and is not, our aim. If (he added), the United States will help us, my wish is that these German Colonies should be internationalised,"—and the Turkish ex-colonies should be similarly treated.

Since Annexation was ruled out, equally with Restitution, there remained only Internationalisation. Anything in the nature of joint administration by a number of nations was admittedly wholly impracticable, and offered only prospects of friction, nor would it have been in the interests of the people concerned. Even a condominium of two nations only, had proved unworkable in Egypt. In Samoa it had led to partition in 1899, and in the New Hebrides it was a source of friction. Nor would such a scheme be acceptable to those Powers which demanded exclusive control over particular colonies. The alternative was the appointment of an individual Power, in whom would be vested responsibility for the administration of each separate territory, as the Agent or Mandatory of the Powers.

For such a course there were precedents more or less analogous. The British and Dutch Royal Charters to Companies—and indeed the Orders issued to Colonial Governors—were written instruments conferring authority to govern as delegates. The Congress of Vienna, in 1859, had deputed Great Britain to control the Ionian Islands on behalf of the Powers. And nearer to our own time, King Leopold of Belgium had, in 1885, been appointed as the Mandatory of the Powers for the Administration of the "International Free State of the Congo," and Prince George of Greece had been similarly appointed to govern Crete in 1898. But the results were not entirely satisfactory, for there had been no clear definition of obligations, and no supervisory body. In the last two cases the Mandate had been issued to an individual and not to a State.

A closer analogy, as Professor Potter points out in the American *Political Science Review* is afforded by the proposal made by President Roosevelt in 1906, that France and Spain should hold a joint Mandate for Morocco, and that they should render to Italy, as the Supervising Authority on behalf of all the Powers, full and complete reports, and that she should have the right of inspection and verification, so as to ensure that all claims to equal commercial opportunity were duly observed. His proposal, however, was never carried into execution.

The creation of the League of Nations, however, afforded just such a supervisory body as was needed. It had neither the funds to meet the immense expenditure involved, nor the machinery to undertake the task itself, but it could provide the supervision over the Mandatories whom the Supreme Council of the Allies might appoint. It had nothing to do with the assignment of the Mandates, or their terms, or the extent or boundaries of the territory. It was not the author of the policy, but the instrument for its execution.

It was thus that the Mandate system became incorporated as a part of the Covenant of the League, and its objects and principles were defined in Article 22 of the Treaty. It had not quite the same international sanction as the Berlin and Brussels Acts, since the United States was not a party to the Treaty, and Germany signed it under duress as a consequence of defeat, but it acquired the sanction of the 50 Powers which constitute the League.

THE ATTITUDE OF AMERICA.

The attitude of America towards the Mandate system is naturally of crucial importance, since she was the only one of the victors who did not sign the Treaty of Versailles, or become a member of the League. She objected to any form of annexation however rigidly conditioned, because she had doubts of the permanency of the League, and if it collapsed conditional annexation would come to be absolute. The policy as regards the inhabitants of these countries, which was laid down in Article 22 of the Covenant, was in accord with her own ideals—assistance and advice to the ex-Turkish colonies until they could govern themselves, trusteeship and tutelage for the backward races in the ex-German colonies. It was on the material side that American opinion was dissatisfied. Though not at war with Turkey, she made no exception as regards the Mandates which referred to ex-Turkish colonies, and claimed full participation for American oil-interests in Iraq. Her ambassador, writing to the Foreign Secretary in May, 1920, stated that "the future peace of the world requires as a general principle that any alien territory which should be acquired pursuant to the treaties of Peace with the Central Powers, must be held and governed in such a way as to secure free and equal treatment in law and in fact to the commerce of all nations." Secretary Colby, in November, 1920, reiterated even more strongly that this principle should govern all Mandate territories, and Secretary Hughes in February, 1921, declared that neither the Principal Powers, nor the League of Nations had the right to award or define a Mandate without the consent of the United States. He regarded the title of all Mandatories invalid without this consent.

Monopolistic exploitation of material resources is, as Prof. Charteris observes, excluded by the nature of the Mandate in the ex-Turkish colonies (Class A). In the B class (Central Africa), however, equal opportunity is assured only to members of the League, and it is not provided for at all in the C class (S.W. Africa and the Pacific). The restriction, or omission of this right of equal commercial opportunity is regarded by the United States as inconsistent with the principles agreed on by the Allies at Paris, and in the Declaration accompanying the "Four-Power Treaty," America again took occasion to stipulate that "the treaty shall not be deemed to be an assent on the part of the United States to the Mandates."

On receipt of Mr. Hughes's note in February, 1921, the approval of the B Mandates for Central Africa was deferred, and the United States was invited to take part in the discussion on them, and on the A Mandates at the next session of Council. The C Mandates had already been approved by Council without reference to America. She did not accept the invitation, and the issue of the Mandates was delayed for a year and a half, while she entered into negotiations with the individual Mandatories. In the spring of 1922, agreement having been reached, the A and B Mandates were confirmed in July, 1922, and it was announced in the Press that formal treaties would follow.

The treaty with Japan (February, 1922), is the only one so far presented for registration. It reproduces the Mandate as confirmed by the Council of the League, and adds that the nationals of the United States shall enjoy the full benefit of all the rights and advantages accorded to the nationals of States Members of the League, and stipulates for equal opportunity, and that a duplicate of the Annual Report shall be sent to the United States. Any later modification of the Mandate, shall not affect the provisions of the treaty without its consent. A treaty was concluded also with Belgium in April, 1923, and received the approval of the Belgian Parliament last February. It has further been officially announced that a treaty was signed last April with France, relating to the French Mandate for Syria, which formally approves the Mandate and stipulates for equal opportunity. An annex to the treaty with Japan announces that the United States had not as yet entered into negotiations as to the Australian and New Zealand Mandates.

The United States has taken a steadily increasing share in the work of the League. She is officially represented on the Opium Commission, on the Committee dealing with the Traffic in Women and Children, on the Health Organisation, and on the Committee on Intellectual Co-operation. She has taken part in several technical Conferences and special problems, and is strongly represented on the League Secretariat. By her insistence in being consulted as to the terms of the Mandates, she inferentially shares responsibility for them. The original conception of the Mandate system has, as we have seen, been attributed to one American President, it owes its adoption to another; and it is to be hoped that before long she will be represented on the Mandates Commission, where her co-operation would be of the greatest value.

DISTINCTIVE FEATURES OF THE SYSTEM.

A Mandate territory, it has been pointed out, differs from a Protectorate in that a Protecting Power obtains rights over the population and against other Powers, whereas a Mandatory as guardian assumes obligations, both towards the League and towards the population, who thus acquire certain rights as against the Mandatory. The most distinctive feature of the system is the unqualified right of supervision vested in the League, which does not however, interfere with the absolute right of the Mandatory to make and enforce laws, to raise troops, to set up tribunals, to appoint officials, and to raise and spend revenues. It is *de facto* and *de jure*, the Government. Mandate territories do not come within the scope of existing treaties entered into by the Mandatory, nor will future treaties affect them unless it is so specifically stated.

The Allies apparently held the view that these territories passed to the victors by cession under the Treaties of Peace, and accordingly the Mandates for the ex-Turkish colonies were merely drafts until the treaty of Lausanne was signed. The United States, on the other hand, maintains, we are told, that they passed to the Allies and Associated Powers, not by Treaty, but as a result of the War, which did not extinguish her rights. It has indeed been maintained by the Judges of Appeal in the High Court of South Africa, that Germany did not cede her colonies to the Allies by the treaty of Versailles, but placed them at their disposal to be administered under Mandate—a status new to International Law.

The restrictions under the Mandates are not imposed upon a subject State, but are treaty obligations voluntarily undertaken—"self-imposed limitations of sovereignty," as Lord Balfour described them. It follows that it is doubtful whether the League of Nations, which did not appoint the Mandatories, has any power to revoke a Mandate,* or whether a Mandatory can claim the right to resign its Mandate without denouncing the treaty in which it had its origin. There is no limit to the duration of a Mandate, and no penalty is prescribed for its breach. The only condition of termination contemplated is when the Mandate territory becomes a self-governing State, and is admitted as a Member of the League by a two-thirds majority. Revocation is apparently only possible if the International Court finds that the Mandatory has violated the terms of the Mandate, and transfer is only allowable with the mutual consent of the Council of the League and the Mandatory. "It is not in the power of the Council of the League, or of the Principal Powers to alter these Mandates," wrote M. Hymans in his report, which was adopted by the Council in 1920: "Amendments can only be made if the Covenant is revised." Lord Milner, Chairman of the Commission for dealing with the Mandates, made a similar statement in the House of Lords. These dicta must be understood to refer to alterations in substance, or to such as are incompatible with the terms of the Covenant, since amendment is provided for in the terms of the Mandate itself, with the concurrence of the Council and the Mandatory, and perhaps also with that of the United States. Such amendments have already been effected by the exclusion of Trans-Jordania from the clauses of the Palestine Mandate referring to the Jewish Home, and by the rectification of the Anglo-Belgian frontier in East Africa—which received the concurrence of the United States.

The Mandate System was thus a compromise between conflicting claims, pledges, and ideals, and in all the circumstances it was probably the best solution possible. It may be argued that Annexation, if limited and circumscribed by the self-same pledges as the existing Mandates, and subject to the same supervision of the League for their fulfilment, would have evaded some of the difficulties which, as we shall presently see, are inherent in the Mandate system, and would in other respects have made but little difference. That no doubt is true, but we have seen that Annexation—*eo nomine*—was wholly impossible.

DISTRIBUTION OF MANDATES.

The Power which had been principally concerned with the conquest of each Colony, or which had special interests in it by reason of its geographical position or otherwise, was selected as its Mandatory. Great Britain accepted the Mandates for Iraq and Palestine, France for Syria. Japan took the islands of the Pacific lately under German rule, north of the Equator, while Australia assumed responsibility for New Guinea and other islands south of the Equator, except for the Samoan group, which fell to New Zealand, and for the little island of Nauru, for which the British Empire as a whole became the Mandatory. South West Africa passed under the control of the Union of South Africa. In the case of Togoland in West Africa, two-thirds were assigned to France and one-third to Great Britain, and in the Cameroons about one-sixth was allotted to England and five-sixths to France. The kingdoms of Urundi and Ruanda in German East Africa fell to Belgium, the remainder, re-named "Tanganyika," to Great Britain; all the British Mandates are conferred upon the King on behalf of Great Britain or the several Dominions. Portugal obtained an adjustment in her favour of long-disputed boundaries in East Africa. There remained Armenia, decimated by Turkish massacres, whose people claimed that the Allies had made definite pledges to them. The Mandate was offered to the United States and refused. For lack of a Mandatory the country, together with Cilesia,—the Mandate for which had first been accepted but later abandoned by France—lapsed again to Turkey. Great Britain was already over-weighted with the responsibilities she had accepted. Whether these Mandates were offered to Italy, which had undertaken none, I do not know.

This omission gave rise to what I cannot but regard as a regrettable episode in these transactions, however urgent were the dictates of expediency. Great Britain and France agreed by the Pact of London of 1915 to compensate Italy by cession of territory if, as the result of these arrangements, they should enlarge their possessions in Africa. The British pledge is about to be redeemed by the cession of Jubaland. Mandate territories are not "possessions," and it would seem, therefore, equitable that the territory thus added to Italy in compensation for the acquisition of Mandates by England and France, should be held under Mandate by Italy, but the promise was made in 1915 before the Mandates system was devised, and it is too late to alter its conditions now.

---

* The Commonwealth Government, referring to the discussion on this subject, categorically stated on April 30th last, that it did not admit the power of the League of Nations to revoke a Mandate without the consent of the Mandatory.

Though the exigencies of a war for existence may palliate exceptional measures, this arrangement was doubly unfortunate. In the first place it revived the immoral idea that territories in Africa could be exchanged as mere chattels or make-weights in a political bargain, and that pledges of protection and treaties with the natives could be set aside and transferred to another, without their knowledge and consent. "British subjects," said the Prince of Wales in reference to a rumoured transfer in the West Indies, "are not for sale." In the second place it gave colour to the assertions of cynics, who questioned the sincerity of the protestations of the Allies, and sneered at their professions of Trusteeship. It gave grounds for the criticism that the Mandates were but veiled annexation, by admitting the principle of compensation. Mr. Lloyd George also used this unfortunate phrase when he alleged that France would be "compensated" for the oil-wells of Iraq by her Mandate for Syria.

MANDATES ALTRUISTIC.

The terms of Article 22 are explicit. Mandate territories are there described as a sacred trust, to be undertaken by nations who (*inter alia*) "by reason of their resources can best undertake this responsibility, and are willing to accept it." The inference that the burden was assumed from high and altruistic motives was explicitly affirmed later. When the Germans urged that the value of their Colonies should be a set-off against reparations, the Allies replied that "the Mandatory Powers, in so far as they may be appointed Trustees by the League of Nations, will derive no benefit from such Trusteeship." On these grounds they justified their refusal to refund to Germany, or to include as part of the reparation payments, the expenses she had incurred in the administration of these Colonies, or the value of the whole of the movable and immovable property. These pledges of disinterestedness thus became in effect part of the treaty in terms of which Germany renounced her Sovereignty in favour of the Allies. She, on her part, while not denying that a transfer of sovereignty involves the cession of all rights in State property, is understood to maintain that the loans raised by these Colonies for railways and public works were purely Colonial liabilities, for which the Imperial Government was in no way responsible.

PROCEDURE ADOPTED.

The Mandates were conferred by the Supreme Council of the Allies, and after acceptance by each Mandatory were submitted to the Council of the League, which was charged with the duty of seeing that the terms were in accordance with the Covenant of the League embodied in the Treaty. There was some unfortunate delay in issuing the Mandates, detrimental to the welfare of the communities concerned, due in part to the difficulty of harmonising the claims of the Mandatories, in part to the necessity for consulting the United States as to their terms. In the meantime their legal position under the Hague Convention was that of countries in military occupation, in which no radical changes in the Civil Administration could be introduced.

It was not till July, 1922, nearly four years after the Armistice, that the Mandates dealing with the ex-German Colonies were issued. By that time it was six or seven years since the German Administration had been ousted in some of them. The delay in the issue of the ex-Turkish Mandates was even greater, owing in the first place to the long-deferred Treaty of Peace with Turkey, which was only concluded at Lausanne last August, and in the second place to a difficulty between France and Italy as to terms of the Syrian Mandate. Meanwhile Palestine and Syria were administered under draft Mandates. Iraq is supposed also to be administered under a draft Mandate, which, however, has never been published. A treaty has in the meantime been concluded between King Feisal and the Mandatory (Great Britain), dated October, 1922. A later protocol limited its duration to four years, or until Iraq becomes a member of the League, England supporting its application for membership. The treaty was subject to confirmation by the Constituent Assembly and the settlement of the Mosul question with Turkey. Thus in the case of Iraq, not only the burden of the Mandate, but the difficult task of settling the area over which it should extend was thrown upon the Mandatory. In the last resort the matter will be referred to the League of Nations—a course to which Turkey has by treaty assented.

THE MANDATES COMMISSION.

The Powers which had accepted Mandates became Mandatories of the League, to which they undertook to submit an annual report. A Permanent Commission was set up by the League in accordance with Article 22, consisting of nine members appointed by the Council, the majority being nationals of Non-Mandatory States. They are selected "for personal merit and competence," as private individuals, and not as representatives of their respective nations. The nationality of the present members is Belgian, British, Dutch, French, Italian, Japanese, Portuguese, Spanish and Swedish, —the latter a lady. The Italian member is Chairman and the Dutch Vice-Chairman. There is a permanent Director (Swiss), an assistant Director (Italian), and a small staff, which receives petitions addressed to the Commission, collects the reports of public utterances in the Press of the world concerning Mandates and events in Mandated territories, and distributes to each member such as merit circulation. A member of the International Labour Organisation attends the Sessions, and takes part in all discussions relating to Labour, including slavery. His co-operation will, no doubt, ensure that "Labour" will be brought into closer touch and sympathy with these overseas territories.

The duties of the Mandates Commission are to see that the various territories are administered in conformity with the terms of the Mandates. For this purpose it meets at least once a year, and examines the report of the Mandatory in the presence of an accredited representative, who replies to questions put to him, or reserves his reply pending investigation. When each report has been reviewed, the Commission draws up its observations for submission to the Council, but each representative has the prior right of seeing the report of the Commission, and of recording a reply if he wishes to do so.

In order that the Mandatory may know the nature of the information desired by the Commission, a printed questionnaire has been sent to each, as a guide for the local Administrator in drawing up his annual report. It deals with the following subjects:—Slavery, labour, arms traffic, trade and manufacture of alcohol and drugs, liberty of conscience, military and defence forces, economic equality, education, public health, land tenure, the moral, social and material welfare of the natives, public finance, etc. It is, of course, the Mandatory, and not the local official, who is responsible to the League, and it is expected, that in forwarding the report of its local Administrator, the Mandatory will indicate whether it differs in any way from his conclusions, to what extent it intends to give effect to his recommendations, and generally to comment on, and identify itself with, the report.

Petitions from inhabitants of Mandate territories must be submitted through the Mandatory, which will forward them with its comments. Petitions regarding the inhabitants received from other sources are reviewed by the Chairman of the Commission, and if they appear to merit attention and are not obviously trivial, they are sent to the Mandatory concerned, for its comments. All petitions so dealt with are finally discussed by the Commission at its next session, and those which appear to call for action are submitted to the Council, with the Mandatory's and the Commission's comments.

CLASSES OF MANDATES.

The Covenant prescribes that the character of the Mandates must differ, in the varying circumstances of each territory, and it indicates three types of Mandate. *Class A* includes the ex-Turkish colonies—Iraq, Palestine and Syria, whose independence can, in the words of Article 22, "be provisionally recognised subject to the rendering of Administrative advice and assistance until they are able to stand alone." *Class B* comprises the Central African (ex-German) colonies—Togoland, Cameroons, Tanganyika and Ruanda. The Mandatory in this case is responsible for the Administration, and undertakes to promote the moral and material welfare of the people. *Class C* includes South West Africa and the Pacific islands, which are to be "administered by the Mandatory as an integral part of its own territory under its own laws, subject to the safeguards named in the interests of the natives."

These safeguards, which apply to the B and C classes are laid down in the Covenant. They are (1) Freedom of conscience and religion, subject only to the maintenance of public order and morals; (2) Prohibition of abuses, such as the arms and liquor traffic, and the slave-trade; and (3) Prevention of fortifications, naval and military bases, and the training of natives except for police and defence. Equal commercial opportunity to States members of the League of Nations is guaranteed in Mandates of the B class only. Since some of the Mandates of the B class, *e.g.*, British Togoland and Cameroons, contain a clause identical with that which in the covenant appears to be peculiar to the C class—viz., that the Mandatory may administer the country as an integral part of its own territory—the only distinction remaining between the two classes is that the B class contains a stipulation for equal opportunity and the C class does not.

NAURU.

The Nauru Mandate presents some peculiar features which merit consideration. Nauru is a tiny island, only eight square miles in area, with 1,084 indigenous inhabitants, but it contains vast deposits of valuable phosphates. A concession to work these deposits was acquired from the Germans by a British company before the War. After the War, in consequence of rival claims by Australia and New Zealand, the British Government intervened, and an agreement, dated July, 1919, was arrived at. The three Governments bought out the British Phosphates Company in June, 1920, for a sum of 3½ million sterling, subscribed in proportions of 42, 42 and 16 (New Zealand), thus converting a privately-owned into a State monopoly. The working of the deposits was vested in a Phosphates Commission of nominees of the three Governments, and each was entitled to a share of the output for home consumption, in proportion to its subscription to the share capital. These transactions, it is important to note, took place prior to the issue of the Mandate.

The Mandate was conferred upon the King, on behalf of the Empire, and was included in the C class, which provides that a Mandatory shall administer under its own laws. But the British Empire has no single code of laws, and in terms of the 1919 agreement, responsibility for administration was assigned by the other two signatories to Australia, for a period of five years. All three Governments send representatives to Geneva to discuss the report on this tiny island with the Mandates Commission, and we learn that in all important matters the Commonwealth Government consults the other two. Prof. Charteris points out that though the joint responsibility of all three is thus fully acknowledged, there is an entire absence of Parliamentary control in any one of the three countries.

The United States took exception to the monopolistic exploitation of the phosphates, but this monopoly existed prior to the Mandate. Whether it was desirable that the Mandate should be conferred upon the States which owned the monopoly, and whether periodical transfer of administrative responsibility (if such is the intention), is in strict accord with the spirit of the Covenant are perhaps, open to question. The phosphates are worked by imported labour—Chinese and other—and the Mandates Commission is concerned with the conditions of these labourers, no less than with the equitable treatment of the indigenous natives.

FAULTS IN THE TERMS OF MANDATES.

Since the Treaty of Versailles was signed the world has learnt from many sources how difficult was the task of the Representatives of the Allies to reach agreement in face of conflicting claims and prejudices, and the sensitive *amour propre* of the different Powers. It is not, therefore, to be wondered at that the high altruistic ideals to which the Covenant gave expression, were found difficult to translate into practice when the spoils of victory were to be divided. It is no small achievement in the circumstances that the signatories bound themselves to the general principle of Trusteeship. There were, however, some derelictions from the conditions laid down by Article 22.

SELECTION OF MANDATORY.

That article very clearly states that in territories placed under an A Mandate "the wishes of the communities must be a principal consideration in the selection of the Mandatory." The neglect of this proviso appears to be irreconcilable with the treaty. The paragraphs in Article 22 on which the B and C Mandates are framed do not contain any similar injunction, though explicit statements had been made in this sense.

TROOPS.

Again, it is difficult to reconcile the terms of the French Mandates in West Africa with the terms of the Covenant. The latter expressly precludes "the military training of the natives for other than police purposes and the defence of the territory," while the Mandates for French Togo and Cameroons, unlike the British Mandates for the same places, add the words:—"It is understood, however, that the troops thus raised may, in the event of a general war, be utilised to repel an attack, or for defence of the territory outside that subject to the Mandate." The meaning is not very clear, but the Press has interpreted it as authorising the Mandatory to recruit troops in Mandate territory in case of a general war, and this precludes the possibility of neutralising these territories in time of war.

In this connexion it may be noted that the Mandates for both Palestine and Syria authorise the Mandatory to make use of the ports, railways, and roads for the movement of armed forces, and of all materials, supplies and fuel, and local forces may be used for purposes other than local defence. These countries would, therefore, as Dr. Lewis points out in the *Law Quarterly*, automatically become involved in any war in which the Mandatory may become engaged. Thus the restrictions on the use of troops recruited in Mandate territories for use elsewhere, which is imposed by the Covenant, and was one of the ostensible reasons for depriving Germany of them, does not apply to A Mandates, only partially to the B class, and it seems quite uncertain whether it applies to the C class or not. The Mandates Commission has recommended the Council that the enlistment of the inhabitants of a Mandate territory outside its borders should be considered as equally contrary to the spirit of the Mandate, and this suggestion has been submitted to the Mandatories for their opinions, and accepted by the British Government. It may be noted that by the terms of the French Mandate it is only troops "*thus* raised," *e.g.*, for purposes of local police and defence, which may be used outside the territory in time of war.

EQUAL OPPORTUNITY.

Apart from these apparent divergencies from the strict terms of the Treaty, the Covenant itself failed to fulfil all the expectations which the pre-Armistice declarations of the Allies had raised. We have already seen that the United States takes strong exception to the limitation of the pledge of equal commercial opportunity to the Central African Mandates, and there only to members of the League. American writers have denounced this action as selfish appropriation of material benefits, contrary to the spirit and implied obligations of the Treaty, and of a Trustee State, and opposed to the declaration of the Allies that they would derive no material benefits from the Mandates. Mr. Bullard, however, writing in an American journal, frankly admits that none of the overseas possessions of the United States which are of any international importance—such as the Philippines, Alaska, and Hawaii—maintain the "open door." "The only nation," he adds, "which has been more extreme in favouring its own trade in its Colonies is Japan." Japan herself, as another American writer points out, contended for the "open door" in C Mandates.

The British Finance Act, 1919, extends to Mandate territories the reduced scale of duties imposed on certain articles imported into the United Kingdom from other units of the Empire. It is, of course, entirely within the rights of any Power to impose, withdraw, or discriminate in regard to the duties it levies upon its imports, and no violation of the principle of equal opportunity is involved, provided that no reciprocity is demanded. It is conceivable that, in some cases, even a mutual preference might be to the economic advantage of the territory and its people, but it is obviously precluded by the terms of the Covenant as regards B Mandates.

Whether, in pursuance of the principle of equal opportunity, the Mandatory should purchase all materials for public works and other supplies in the cheapest market, and not necessarily in its own, and whether loans for the development of the territory should similarly be open to International subscription, are points which have so far not presented themselves for discussion. It is, however, clear that the altruistic ideal cannot with safety be carried too far, and unless the Mandatories, which have spent large sums upon the territories under their guardianship, are allowed to derive such advantage as close touch may afford, the Mandate system will become unpopular. It may be noted that the cost to the British taxpayer of the Mandates for Iraq and Palestine, as stated by the Under Secretary a year ago, showed an average of £38,128,342 per annum for the previous four years, and that for Tanganyika (three years' average) was £681,333 per annum. The Cameroons cost about £30,000 per annum, which is paid by Nigerian funds.

It seems very regrettable that the principle of equal opportunity was not extended to C Mandates, and, in my personal opinion, it would have been wise, whether Germany joined the League or not, to throw open the door to German commercial enterprise in her former Colonies, where it is to be hoped that she would see a better system of administration under the Mandates than she had adopted in regard to the natives. To deny access to direct sources of supply of tropical raw materials and markets, vitally necessary to an industrial nation of sixty million souls, must necessarily engender bitterness and resentment, and add to the incentives for a new war.

OTHER MATTERS.

It may also be noted that the obligation to grant equal opportunity which is restricted to Members of the League applies also to missionaries, and this seems hardly compatible with the clause enforcing freedom of conscience and of religion.

A further subject of regret in the allotment of the Mandates arises from the fact that in some cases scanty regard has been paid to native interests, since the new political frontiers often intersect tribal areas. In East Africa a portion of the ancient kingdom of Ruanda had been assigned to England, in order to afford access for a possible future railway connecting Uganda with Tanganyika. Representations were made by the Mandates Commission, and Great Britain willingly ceded unconditionally the area in question to be included in the Belgian Mandate. Similar representations have been made in regard to tribal areas in the Cameroons, and are now under consideration.

Some difficulty has also been experienced from the looseness of the terms employed in the Covenant, as for instance, the term "Liquor Traffic." The interpretation given the other day in the House of Commons by the Colonial Secretary, viz., "The importation of cheap distilled liquors for sale or barter as an article of trade with the Natives," is undeniably the sense in which it has always been used in West Africa, but there are those who hold that the abolition of the Liquor Traffic means total prohibition. This would be in manifest divergence from the Treaty of St. Germain, concluded by the same Allies very shortly afterwards. (September 10, 1919.) Many other instances could be cited.

INHERENT DIFFICULTIES.

With such defects in the Mandates the Mandates Commission has no direct concern, unless (as in the last quoted case), they form the subject of a complaint or petition. Since, however, the Mandate system constitutes a new departure in International Law and policy, it will be of interest to note some of the difficulties which have presented themselves, and the steps taken to consolidate the system.

The lack of any means of verification of the reports submitted—such as was contemplated in President Roosevelt's proposals—and of ascertaining whether they represent a true and impartial picture, without omission of any matters which ought to have been included by the Local Administrator—of which the Mandatory may itself, perhaps, be unaware—naturally militates against effective supervision. Outside critics are naturally reluctant to draw attention to such matters. In some cases they may fear that to do so may be prejudicial to their own material interests. The League is thus deprived of the only means at its disposal of enforcing the execution of the Mandate, viz., publicity and the force of public opinion, especially in the Mandatory country itself.

LACK OF PERMANENCE.

The term "Mandate" implies "un titre précaire," as M. Ryckmans calls it, and this unfounded fear of lack of permanence is a manifest obstacle both to the guaranteeing of loans by the Mandatory—by which better terms of flotation can be secured—and to the expenditure of capital in the country by the Mandatory or by private enterprise. If there were any uncertainty as to the continuance of the Mandate, the only security for investments by the Mandatory would be a lien on the railways or other public works for which the loan is required. But if the Mandatory owned the railways in its own right, it is argued that this would be tantamount to Annexation. This difficulty might perhaps be minimised if every loan was open to public subscription, not confined to the Mandatory nation, and if the security for any guaranteed loan consisted in a first charge on the revenues of the territory,—a liability transferable with the Mandate itself, should such a contingency arise. The Syrian Mandate contains a clause designed to safeguard the financial obligations incurred during the continuance of the Mandate.

We have already seen that the Mandates have no time limit, and that for all practical purposes transfer is impossible and revocation unthinkable, but colour has been given to these suggestions of instability by proposals made in Parliament, and by responsible organs of the Press, that Great Britain should abandon the Mandates for Palestine and Iraq, on account of the heavy burden they have imposed on the British taxpayer, and it is within my own knowledge that would-be purchasers of the ex-enemy estates in Africa have been deterred by the same fear of insecurity of title. France, it is pointed out, resigned her Mandate for Cilesia; but her acceptance was only provisional, and no Mandate had been issued.

Voluntary resignation of an accepted Mandate—even if feasible without denouncing the Treaty under which the obligation was incurred—would be contrary to all British tradition, and no party in the State has been found to advocate the abandonment of a task to which this country has set its hand. The geographical and political reasons which prompted the acceptance of the Mandates she holds would still deter her from consenting to transfer them to other hands. But if, in spite of these considerations, private capital hesitates, and banks refuse to advance money on mortgages, the only satisfactory solution would seem to be that the Mandatory itself, being assured of the permanency of its retention of the Mandate, should give a guarantee against voluntary transfer or revocation. This would assure to private investment the same security that it would enjoy in a British Protectorate—and more cannot be reasonably demanded — and remove the economic disability under which a Mandate territory suffers.

A word regarding the ex-German estates, which for some years past have been advertised for sale, may be of interest. Under Article 260 of the Treaty, Germany was called upon to indemnify her nationals who were possessed of any rights and interests in her former colonies—their value being credited to Reparation account. Plantations formerly owned by German companies or individuals are not, therefore, the property of the Mandate Government, and whether sold, or retained and exploited by the State which holds the Mandate, their capital value and profits belong to the Reparation Fund. They are, however, like any other property, subject to taxes on behalf of the Revenues of the Mandate territory, and no preferential treatment in respect of labour supply or otherwise can be accorded to them, even though retained by the Mandatory State.

STATUS OF NATIVES.

An initial difficulty was experienced in determining the status of the inhabitants of a Mandate territory of the B and C types. Since the territory was not annexed, it was universally agreed that they did not become nationals of the Mandatory Power. After much discussion the Council adopted the formula that "it is desirable that the native inhabitants should be designated by some form of descriptive title which will identify them as such," *e.g.*, as "persons administered or protected under Mandate." This does little to identify them with the Mandatory, and so deprives them of the incentive to loyalty and patriotism which counts for so much in the adjacent Colonies and Protectorates. It confers no juridical status, and no privilege of citizenship, but Article 327 stipulates that they shall be entitled to the diplomatic protection of the Mandatory outside the Mandate territory.

In pursuance of a suggestion by the Mandates Commission, the Council declared that it was not inconsistent with the conditions of a Mandate that the inhabitants of the territory should voluntarily obtain naturalisation from the Mandatory Power, in accordance with its own laws. The matter was brought forward by the Australian Government at the last Imperial Conference. British nationality cannot be acquired by residents in a Protectorate,—which is not British territory,—but the Conference approved that the power of granting certificates of Imperial naturalisation should be extended so as to cover persons resident in B and C Mandated territories, and also in certain named Protectorates. Similarly the Foreign Office lately agreed that the existing Extradition Treaties with France should be extended so as to apply to specified Protectorates, the inhabitants of which should for this purpose be "assimilated" to those of a Possession or Colony. England has been more unwilling than any other nation to grant any status to a Protectorate, the need for which is shown by admissions such as these. I am not aware of the precise status of natives in a foreign Protectorate, but ours should not be inferior to them.

The question of Germans resident in S.W. Africa raises a separate problem, and the Union Government was authorised by the Council, apparently with some reluctance, to pass a general naturalisation law, without prejudice to the question whether the Mandatory system applies equally to non-natives as to natives. Any person may refuse naturalisation without any penalisation in practice. In the A class of Mandates, a local nationality as a stepping stone to self-government is, in theory at least, possible.

PARTICIPATION IN CONVENTIONS.

Mandate territories occupy, as we have seen, a status new to International Law, and, as the Mandates Commission has pointed out, International Conventions applicable to the adjacent Colonies and Protectorates of the Mandatory do not apply to them. They are, therefore, "liable to have their rights of free movement questioned, and also their rights to carry on trade and to own property outside the Mandate country. The benefits of the most-favoured-nation clause included in commercial treaties have been refused in the case of goods coming from a territory under a B Mandate, while products of the same kind coming from contiguous protectorates of the Mandatory State enjoy the benefit of this clause on being imported into the same country of destination." The Commission, therefore, recommended that all States Members of the League should accord to Mandate territories a status identical in this regard with the adjacent territories of the Mandatory, provided that the principle of economic equality in the B class is not infringed. The matter has been referred to the Mandatory Powers, and Great Britain will, I understand, reply in a not unfavourable sense. While pointing out that commercial treaties confer no personal privileges on the inhabitants and that such treaties do not apply to all Protectorates, she will, I understand, be willing to consider favourably any case submitted.

A FORWARD STEP.

These instances will serve to illustrate some of the questions which arise in connexion with the Mandate system. It is, indeed, obvious that every effort to avoid the charge of Annexation, and to accentuate the distinction between the territories held under Mandate, and the adjacent territories under control of the Mandatory, must *pro tanto* accentuate the apparent instability of the system. It is as though one should endeavour to abolish the distinction between the holder of a lease in perpetuity and a freeholder. Since it is the general desire in this country that Germany and Turkey should join the League, it is well that such difficulties should be cleared out of the way before they do so. But though it is of interest to examine in some detail the working of a system new to International Law, initial mistakes, or temporary difficulties, must not be allowed to obscure the fundamental basis of the system. The principle thus accepted, and embodied in the Covenant and the Mandates, is that of Trusteeship, and of public responsibility to a supervisory authority for the execution of the obligations laid down in the Trust deed. It is the acceptance of this principle, whether it be formulated as a Mandate or as restricted appropriation, which constitutes the claim to progress.

The Annual Report forms an effective means of inviting a popular verdict on the fulfilment of the Trust. Neither the Mandates Commission, nor the Council, nor the Assembly can exercise any coercion, for the Mandatory, as Lord Balfour observed, is under the supervision and not under the control of the League. The ultimate authority to which the stewardship of the Mandatory is submitted is the public opinion of the civilised world.

TASK OF THE MANDATES COMMISSION.

The Mandates Commission, which includes men with personal experience of administrative responsibility, who can realise local difficulties, and appreciate the futility of hypercritical comments, or interference with the discretion of the Mandatory, should in course of time become a valuable body, with a varied knowledge of Administrative problems in every part of the world. Its international composition ensures that its suggestions, made in consultation with the representative of the Mandatory, shall be devoid of any suspicion of bias. Its task is to promote co-operation,—which may extend beyond the frontiers of the Mandate territory,—and to eliminate friction, while fearlessly exposing any manifest breach of the Mandate. The reports submitted have, generally speaking, been very full—indeed, in some cases, of embarrassing length; the specially accredited representatives have been men of eminence and knowledge; the discussions have been practical, and I think we are justified in believing that they have served, and will continue to serve, a useful purpose. Each Mandatory has been anxious to shew that it has not been backward in carrying out its pledges.

It is no mean achievement that the conquerors have (as Lord Balfour said), agreed to a self-imposed limitation of the sovereignty which they obtained over conquered territories, and consented to the supervision of the League. The high standards embodied in the Covenant must obviously in future be regarded as principles of general application. The responsibility is one which the advantages of an inherited civilisation, a superior intellectual culture, and twenty centuries of Christian ethics, no less than the physical superiority conferred by the monopoly of firearms, imposes upon the Powers in their dealings with the Backward Races. The Mandate system stands as an International acknowledgment that civilisation must be made to mean something higher to them than the aims and methods of the development syndicate, or the assiduous cultivation of new wants to afford markets for European commerce.

DISCUSSION.

Sir Horace A. Byatt, K.G.M.G., in opening the discussion, described how the Mandate system worked in the Tanganyika Territory, which it had been his privilege and honour to administer for the last seven years. Sir Frederick Lugard had referred to the unfortunate delay which had occurred in the issue of the Mandate; but from the point of view of local administration that delay, in some ways inconvenient, had been by no means regrettable, because it had given those in authority time to look round, to study local conditions, to come to know their people, to ascertain the people's real needs, and to formulate a policy on the lines which they supposed would be laid down by the Mandate. They had been able to anticipate to a very large degree the principles which had ultimately been laid down. There had been a little anxiety and uncertainty as to what the Mandate might impose, and as to what restrictions might be passed, but it had been a very great surprise and pleasure, when the Mandate at last appeared, to find that there was nothing in it which necessitated any change of policy. In the time which they had had at their disposal, they had already, if not actually enacted, at any rate progressed a long way towards the enactment of, such laws as the Mandate required them to promulgate; that was to say, they had dealt with the protection of natives from usury, with traffic in firearms, with the liquor traffic, and, either before or just after the issue of the Mandate, legislation had been promulgated which ensured security of tenure of land to the natives, not only for their present needs but for the needs of the future, taking into account their natural expansion. He desired to emphasise that when the Mandate was issued they had found that it embodied what he might call the unwitten Constitution of the British Colonies in Africa. It merely put down in black and white those abstract principles of justice and of trusteeship to the natives which had been adopted as a matter of course, and which were not in any sense forced upon them by the Mandate.

A good deal had been said about the burden which Great Britain had assumed in accepting responsibility for the government of these mandated territories. He wanted to show that that burden was not a great one, and that it was not likely to be a lasting one. There had been a good deal of adverse comment at various times in the Press—obviously made by people without sufficient knowledge. He had read, for instance, in the "Trade Supplement of *The Times*," and in other publications, various criticisms which were not at all justifiable. It had been said in one paper that Tanganyika was overrun with officials, and that Great Britain had twice the staff which the Germans had had; that the country was not half so well governed, and that, for that privilege, the British taxpayer was called upon to find a million sterling per annum. It was also said incidentally that the railway was the worst offender. As a matter of fact he had found, after searching carefully through the German records of 1913-14 that the number of European officials employed in German days had been 1,120, whereas the number employed by the British Government to-day was 860. On the two railways, the Central and the Northern, the British Government now employed 153 European officials, whereas on one railway only in the German days 149 had been employed; he had not been able to find the German figures for the second railway. He had noticed on another occasion that a certain speech which he had made had attracted a good deal of comment. In that speech he had referred to the necessity of improving the harbour facilities at Dar-es-Salaam, and also to the necessity of improving the railways. It had been said that if any improvement was required it was at Tanga, since the latter dealt with the bulk of the trade, and that it had behind it the great bulk of the native population. The plain facts were as follows. The value of the trade passing through Dar-es-Salaam was £1,370,000, and of that passing through Tanga only £608,000. The native population in the hinterland of Dar-es-Salaam was 1,482,000, and in the hinterland of Tanga, 450,000. He merely quoted those figures to show that somewhat unfair comment had been made.

Tanganyika had undoubtedly been a burden on British taxpayers so far, but he thought it was impossible for anyone who had not resided in the country to realise the enormous damage and the complete destruction which had been effected by the War, and what a tremendous amount of reconstruction work was necessary, and the expenditure which that entailed. The burden was gradually decreasing. At no time had the British taxpayer been called upon to pay a million per annum. Sir F. Lugard had given the figure for last year, which was something over £600,000. In the present year it would be only £300,000. The trade of the country was increasing so rapidly, and the revenue improving to such an extent, that he looked forward to the time when Tanganyika would no longer be a burden on the British taxpayer, but would pay its own way. If one left aside the capital expenditure on reconstruction and the deficit on the railways, (a deficit that was rapidly diminishing), in the present year the difference between ordinary expenditure and normal revenue would be only some £30,000, and he had no doubt that next year that difference would be entirely eliminated.

With regard to trade, they had followed a policy entirely in accordance with the principles of the Mandate, namely, of encouraging native production. They had afforded the native opportunities, which he had never had in the German days, of becoming a small producer and of selling his crops in a good market. The result had been somewhat astonishing. In every commodity a very large increase had been shown over the German record figures. Twice as much coffee had been produced as in the German days, and with regard to ground nuts, whereas the Germans had produced 8,000 tons, last year 16,000 tons had been produced and this year 20,000 tons were expected and of grain two to three times the maximum amount exported by the Germans had been exported. The same could be said of most other commodities. He had no doubt whatever that in all commodities the German records of produce would be far surpassed.

He offered these remarks in order to show that the Tanganyika Territory as a mandated territory was not likely to be a burden on the British Empire. He had every confidence in stating that in the course of a very short time it would be a flourishing and a prosperous appanage of the Empire.

The Chairman (Lord Milner), said everyone must have listened with great satisfaction to the remarks of the last speaker. Speaking for himself as one who had had some experience of Colonial administration, he always found it particularly difficult to listen with patience to the complaints which were so often made in this country about the burden of our Colonial possessions. In the case of Tanganyika it really was ridiculous ever to have made a fuss about even the largest sum which we had been obliged to spend there if one considered the conditions of the country when it was taken over by Great Britain. Experience had shown us over and over again in scores of cases but we have never learned the lesson, that the liberal treatment of our Colonial territories, though it might involve for a few years a financial burden, rarely of considerable amount, invariably in the long run led to a development of the resources of those Colonies which directly relieved us of the burden and indirectly brought a very considerable accession of wealth to this country. There were a great many arguments other than financial for a liberal policy of Colonial development, but looked at from the purely financial point of view, in nine cases out of ten such a policy was in the long run not burdensome at all but very profitable. He was almost afraid to dwell on this point, although it was certainly the truth, because people turned round and said "Oh yes, finance is all you care about." It was not all he cared about as far as the Colonial Empire was concerned—very far from it; but he did think it was worth while to emphasise the point in order to get rid of an objection and a criticism which often did infinite harm by preventing a liberal administration of our Colonial possessions, especially in their early and struggling stages.

Turning now to the address, he had been particularly struck by the clear and absolutely correct analysis given by Sir F. Lugard of the conditions which had led after the conclusion of the War to what he might call the invention of the mandatory system, and of the influences which had brought it about. He would only add to what had been said that if the mandatory system had been called into existence mainly as a way out of the dilemma which Sir Frederick Lugard had described, it had been also partly the outcome of the idealistic spirit in which immediately after the War a great many people had approached the problem of world resettlement. Speaking for himself he had felt great sympathy with the mandatory idea, for he had hoped—when he came to look back upon it he saw that the hope was not altogether reasonable—that the spirit of cordial and unselfish co-operation which had been attained with difficulty but nevertheless ultimately attained, by the allied nations in the conduct of the War, would survive during the period of reconstruction, and especially that it might lead to a good settlement of the countries which the collapse of the German and Turkish Empires had left upon our hands and which it was the duty of the victorious nations to provide with some new form of government. It had, however, to be admitted that in the long-protracted negotiations which had resulted in the Mandates, such as they were, that spirit had been not only not always apparent but very often submerged by a return of the old rivalries and ambitions. If the hope to which he had referred had been fulfilled, and if the Mandates could have been brought into force with reasonable promptitude some great disasters would have been avoided, such as that which had befallen the Christian population of Armenia. More than that, the mandatory system might have acquired a prestige which would have enabled it to be gradually extended to other portions of the world in which it seemed that the native populations were incapable without external aid of evolving any decent form of government. But fate had willed it otherwise. As things had actually turned out it seemed to him that the mandatory system, so far from obtaining greater extension, was likely as time went on to be contracted and to prove in many cases a mere transitory stage. Nevertheless, it remained even in its curtailed and more or less mutilated form—he meant as compared with the original big conception—a very important factor in the international situation. Therefore, it was well that we should take counsel as to the best use which could be made of it, and the best way in which the difficulties inherent in it might be met.

The lecture to which they had just listened was a very great contribution to the study of the subject. There were only two or three points of detail on which he would like to touch. With regard to C Mandates, he thought it was evident that the countries comprised in them had become or were becoming simply incorporated in the territories of the respective mandatory powers. No doubt the mandatory Powers held them under certain obligations. Those obligations were not at all onerous, certainly as far as the British Dominions were concerned, and also Japan probably. They imposed upon the mandatory Power no duty which it would not be obliged to discharge out of regard for its own principles and reputation as a civilised Power. He did not wish to underestimate the advantage which arose from the fact that those duties had now got an international sanction. No doubt it strengthened the hands of those people who in any of the mandatory countries were earnestly desirous of seeing that the power of their country should be exercised for the benefit of the backward races under its control.

With regard to B Mandates, the position was not equally simple. Sir F. Lugard had referred to two points especially with regard to which difficulties had arisen or might arise, namely, the question of recruitment of the natives of those mandated territories for military purposes, and the principle of equal opportunity for all States members of the League in respect of the commercial development of those countries.

It was certain that neither of those principles could be enforced with absolute rigidity. A certain freedom of interpretation was necessary. In the case of the recruitment of native levies, France had insisted on a fundamental modification of the Mandate for the Cameroons as originally drafted. With regard to the question of equal opportunity, personally he held that it was both right and necessary, having regard to all that had been said and what was laid down in the Mandates themselves, that mandated territory should be free to the commercial enterprise of all members of the League (he would go further and say of all nations). But it would be a mistake and would be fatal to the development of the mandated territory itself if the hands of the mandatory power were too rigidly tied about the financial arrangements which were essential for any honest effort to develop fully the resources of the country. It was a question of the reasonable interpretation of the Mandate—of looking to its spirit rather than to its actual letter—and personally he felt no doubt that if this question was ever raised the Mandates Commission would give a reasonable interpretation, and one in the interests of the mandated territory itself, to the principle of equal opportunity.

He observed that Sir F. Lugard had not said very much about the A Mandates. He was not surprised at that because it was not a cheerful subject of contemplation. Certainly it had been in everybody's mind when the mandatory system was first started, that it should be applied to Armenia and to certain other portions, never quite adequately defined, of the Turkish Empire in Asia. Those projects had long since passed in the limbo of bygone and forgotten dreams. It would have been very much better for the world and for the unfortunate Christian inhabitants of those countries if they could have been realised. With regard to Mesopotamia, frankly he did not know where we were. The one thing which was certain was that whatever might be the ultimate fate of Mesopotamia the Mandate for it would never materialise. That left, therefore, of the A Mandates only those for Syria and Palestine. He could not speak from personal knowledge about Syria, but Palestine did, in his opinion, present the best illustration possible of what could be accomplished under the mandatory system. He thought the difficulties besetting British administration in Palestine, though they were very real, had been somewhat exaggerated. There were two statements with regard to that country which could not be controverted. One was that in respect of order, justice, sound administration and material prosperity it had made a degree of progress in the past six years which would have been totally impossible without disinterested external aid. And the other was that, owing to the unique history and character of that country, to the fact that it was sacred soil for three great religious communities, and was of peculiar interest to the whole civilised world, it was a country to which the principle of the mandatory system, the principle of trusteeship, was peculiarly appropriate. One could never contemplate Palestine being the property of any single nation. One could not contemplate its being exclusively possessed by Moslem, Jew or Christian. They all had their rights on that sacred soil, and those rights could only be harmonised under the trusteeship of some impartial authority.

Hon. W. Ormsby-Gore, M.P., hoped Sir F. Lugard's paper would find its way into the Government offices both here and in the mandated territories, because one of the most remarkable things was that there was still extraordinary ignorance both as to the obstacles and the difficulties on the one hand and as to the most elementary facts on the other. The main obstacle as he saw it was the lack of sense of security in the title of the Mandate. Practically all the troubles and difficulties had arisen from that fact. Sir Horace Byatt had said he thought the trouble was becoming easier from his point of view, but he could assure Sir Horace that the difficulty of getting a penny out of the Treasury for a mandated territory was enormous. It was difficult enough to get a penny out of the Treasury for the Colonies; it was still more difficult to do so for the Protectorates, and it was quite impossible to do so for mandated territories. That was true both of public and private enterprise. There was the greatest difficulty in disposing of ex-enemy properties in those territories. People enquired "What is this mandatory business?" They were suspicious of it. They had it at the back of their minds that such territories might possibly go back to Germany. Frankly, we had been faced with the difficulty, under the mandatory system, of attracting either public capital or private capital for the purposes of the development of those countries. He expressed the hope that the Permanent Mandates Commission would not merely content itself with being a critical body but would co-operate in a really constructive policy for the development of the mandated territories and would endeavour to bring in the whole public opinion of the world towards a solution of the problem which arose in those territories.

Lord Askwith, K.C.B., K.C., D.C.L. (Chairman of the Council), in proposing votes of thanks to Sir Frederick Lugard for his paper and to Lord Milner for presiding, said the paper was the clearest account of the question that he had ever heard, and stated a lot about Mandates of which most people did not know. Sir F. Lugard had been a man who for more than a generation had had great faith in the British Empire, a great belief in British commerce and a great trust in British administration.

He did not think that either Sir F. Lugard or Lord Milner had spoken with very great enthusiasm about the system of Mandates—a system which had arisen from some of those unfortunate phrases like "No annexations," "Self-determination" and so on.

What Lord Milner had said about the position of the mandatory countries was to his mind quite correct; but the time might come when, with the progress of the world, the people in those mandatory countries, one country after another, would ask for a change themselves. He confessed he would not care to be a citizen in a mandatory country and not to be able to say that he belonged to a great nation, but to have to say that he belonged to a country which was mandatory class A or mandatory class B., or mandatory class C. Some of those mandatory countries were going off already; others, some people said, we should give up; but others might remain for some considerable time. The difficulties with regard to administration and trade might lead to many changes in the future.

Sir Robert W. Hamilton, M.P., who would have taken part in the discussion if time had permitted, writes that the points which he intended to raise were the following:—

1. The status of mandated territories, and the manner in which that status should be made obvious to the world by the use of a flag.
2. The individual status of the inhabitants of a mandated territory, and how the suggestion of the grant of Imperial certificates of naturalisation could be carried out in practice, and if carried out, how far such grant would be consonant with the trustee idea.
3. The inevitable tendency for a mandated territory to be absorbed into the government of the Mandatory, and the conditions that would be likely to arise in the case of the federation of neighbouring colonies and mandated territories.
4. The extreme importance (with regard to Class B mandates in Africa) of the attempt to administer areas in tropical Africa in accordance with the spirit of the mandate, and free from any idea or suspicion of exploitation in the interests of the governing power, or of any class of individuals resident within the territory.

He desired (he adds) to raise these points rather with a view of eliciting information and stimulating discussion than to give any considered opinion on them himself.

THE RESOURCES OF PAPUA.

The following particulars regarding the resources of Papua have been collated by the Far Eastern Division of the United States Bureau of Foreign and Domestic Commerce, and published in the official "Commerce Reports":—

With a fertile soil capable of raising practically anything grown in the Tropics, with adequate rainfall, with deep and navigable rivers and excellent harbours, with valuable mineral deposits, with liberal land laws and easy-settlement terms, and with large sums of money already invested in plantations, shipping, and trade interests, Papua—one of Australia's richest dependencies—seems destined to become an important commercial market.

Lying north by north-east of Australia and separated from that country by Torres Strait, Papua (formerly known as British New Guinea) comprises the south-eastern part of the island of New Guinea, together with the outlying groups of islands—Trobriand, Woodlark, d'Entrecasteaux, the Louisiades, the Conflict group and the Laughlan group. The territory has 1,728 miles of sea-coast on the mainland and 1,936 miles of island coast. The total area of Papua is approximately 90,000 square miles. In 1922, the white population of the territory numbered about 1,104. Much of the interior of the country has never been explored. The native population is estimated at from 250,000 to 350,000.

The products of Papua are obtained from its agriculture, its forests, its fisheries, and from mining and manufacturing.

The physical features of Papua are especially favourable to agriculture. The territory lies wholly within the Tropics. Its northernmost point is only 5° south of the Equator and its southernmost portion between 11° and 12° south. The country is remarkably well watered and it lies outside the hurricane belt of the south Pacific —a most important fact. Along the coast are immense areas of rich alluvial and volcanic soil, and even at an altitude of 6,000 feet the land is fertile.

In areas running back from the coast, where the soil is dry and rainfalls come at long intervals, conditions are said to be particularly suitable for the production of tobacco, fibres, etc. In 1920 the total agricultural area planted was 58,347 acres, averaging 237 acres to each plantation, the principal crops being coconuts, rubber, and sisal hemp. The natives are compelled by ordinance to plant coconuts for food supply. Secondary agricultural products of Papua include bowstring hemp, kapok, coffee, tobacco, vanilla beans, cacao, tapioca, cinnamon, tea, rice, and maize. Sugar cane also flourishes in the south-eastern part of the territory. Figures prepared in December, 1920, showed areas under cultivation as follows: Coconuts, 44,328 acres; rubber, 7,250 acres; hemp, 5,856 acres; miscellaneous crops, 900 acres. The quantity and value of products for the year ended June 30, 1921, were: Copra, 2,984 tons, worth £68,578; hemp, 188 tons, valued at £723; and rubber, 220 tons, worth £28,966.

The indigenous products of Papua include sandalwood and other timber, sugar cane, cotton plants, nutmegs, ginger, bamboos, palms, bananas, breadfruit, edible nuts, fruits, and vegetables. Forest products which have been catalogued show 120 varieties of timbers, 16 of which are adapted for use for girders, railway wagons, etc.; 10 for railway carriage and coach building; 15 for joinery, lining, floors, etc.; 15 for butter boxes; 5 for boat building; 4 for piles; and 15 for cabinetwork.

The highlands of Papua have immense possibilities for pastoral and dairying pursuits, the native grasses being particularly succulent.

Papua is rich in mineral deposits, which have been located over a very wide area. They include gold, copper, tin, lead, zinc, cinnabar, iron, osmiridium, gypsum, manganese, sulphur, graphite, chromite, brown coal, and petroleum. Large beds of apparently good coal are believed to exist. The total value of gold mined to June 30, 1921, was £1,567,168; while copper production during the period amounted in value to £114,795.

On account of the depth and force of the principal rivers of Papua the territory is exceptionally favourable for the introduction of hydro-electric schemes. The estimated water-power available for this purpose is equivalent to 10,000,000 horse-power.

TOBACCO INDUSTRY OF SOUTH AFRICA.

Tobacco-growing in South Africa has been steadily increasing during the past ten years. According to a report by the United States Consul at Cape Town, the area under cultivation at the present time is 26,000 acres and a variety of types are grown in the different Provinces. In the Transvaal a light and medium tobacco of the Virginia type is produced; in the south-central part of the Cape Province a medium to heavy type of Virginia is grown; and in Natal a medium dark tobacco is grown and used in the manufacture of cigars and a cheap grade of pipe tobacco. In the western part of the Cape Province Turkish Tobacco, such as Dubeck and Soulouk, is grown. The bulk of the tobacco produced is of the light to medium Virginia type. The Turkish leaf grown (amounting to 750,000 pounds) does not meet the demand.

The total production of all tobaccos grown in South Africa has been as follows: 11,644,000 pounds in 1920, 16,620,000 pounds in 1921, 13,000,000 in 1922. Frost and fire caused considerable damage to the 1923 crop. There are three co-operative tobacco societies in the Union of South Africa, the largest being the Rustenberg Farmers' Co-operative Society, which handles between 3,000,000 and 4,000,000 pounds of tobacco annually.

In 1920 there were 66 tobacco manufacturing plants in the Union, employing 2,662 persons. These plants have been using an increasing quantity of tobacco grown in South Africa and Rhodesia, and a decreasing amount of imported tobacco. For instance, in 1916, the raw tobacco consumed consisted of 8,000,000 pounds of South African and 466,020 lbs. of imported tobacco. In 1920 there was used 12,500,000 pounds of South African, 1,500,000 pounds of Rhodesian, and only 211,307 pounds of imported tobacco.

The full amount of tobacco which can be consumed within South Africa is now being produced, and if the output increases oversea markets must be found.

THE FRENCH OCHRE INDUSTRY.

The industry of extracting and preparing ochre is developed to a larger extent in France than in any other Euorpean country. The production is centred in two Departments—Yonne and Vaucluse —but while the production of Vaucluse is considerably smaller in quantity than that of Yonne, it is of superior quality both in colour and texture, and the output has a higher total money value.

From a report by the United States Vice-Consul at Marseilles, it appears that the title to ochre beds rests entirely in the landowner, who is generally a small farmer. No mining concession is needed for extraction, which is, in general, a seasonal occupation of the peasants.

An estimate from a reliable source places the ochre production of the Apt (Vaucluse) region at 20,000 metric tons for 1922, as compared with approximately 60,000 tons for the last year before the war. The latest official figures (1920) showed about 11,000 tons produced.

The crude product is generally treated near the pit, and on the same property, but none of the product is consumed at the pits nor in the centres of production.

Ochre in barrels is bought and sold by a number of companies, some of which also exploit their own properties. There is no further preparation in France after the pulverised ochre is placed in barrels, marked and tested.

The product of Vaucluse finds a ready market in the United States and in Great Britain, the former taking about 50 per cent. and the latter about 35 per cent. of the total production. Exportation is through Marseilles. The product of the Department of Yonne goes largely to northern French ports.

It is said that by careful grading in foreign countries a mixture is made of ochre from the two French fields which gives excellent results. No such mixtures, however, are produced in France.

COPPER COINS IN CHINA.

The various mints in China during the past few years have turned out enormous quantities of copper coins. According to the United States Commercial Attaché at Peking, it is estimated that those now in circulation in the country number about 40,000,000,000. Copper is in reality the medium of exchange of the masses. With the fall in copper prices, and the wholesale minting of these coins in China, including the production in some cases of light-weight coins, the value of the copper cent has continued to fall, and has reached such a low level that many mints have discontinued its coinage as being no longer profitable. There is still, however, one other difficulty and that has to do with the issue of copper cent notes. These have been circulated on about the same basis as the value of the copper coins, and have shown little tendency to depreciate, except in cases of certain provincial issues other than those of the central Government.

This situation has had a serious effect upon the economic life of the people for the reason that the copper is the coin of the masses, and its depreciation affects their purchasing power very seriously. This is particularly true in the factories and modern industrial plants, where wages have been placed upon definite schedules. Among the farming population prices more easily adjust themselves, so as to cover any discrepancy regarding depreciation of currency.

CHINESE BANKS IN HONGKONG.

There are eight organised Chinese banking companies, with a paid-up capital of 25,000,000 Hongkong dollars and estimated deposits of 45,000,000 dollars, in Hongkong. According to the United States Consul at Hongkong, the number of these banks has doubled since 1918, and the volume of business done by them appears to be steadily increasing.

Modern Chinese banks in Hongkong employ methods similar to those used by the local foreign banks. They are registered and are governed by the ordinances of the Hongkong colony. They encourage foreign trade by the use of modern methods of financing, particularly through utilisation of the commercial letter of credit and acceptances. It is noteworthy that Chinese banks are increasing their connections in the United States, these being wider than those made with European countries. The European war was the most influential factor in effecting this result.

Besides the modern Chinese banks, there are about 25 native banks conducted in accordance with old Chinese customs, and these do a profitable and large business in Hongkong. Their operations are mostly confined to loans, mortgages, and the financing of shipments between ports and trade centres in China.

There are also about 300 money changers in Hongkong, with capitals varying from 5,000 to 50,000 Hongkong dollars. Their dealings are more directly with the masses, and a profitable return is secured on the business handled.

GENERAL NOTE.

Victoria and Albert Museum.—The Victoria and Albert Museum has recently purchased, with the assistance of a grant from the National Art-Collections Fund, a Writing Cabinet, signed "Samuel Bennett London Fecit". This is an important example of English furniture of the time of Queen Anne, made of walnut wood, with marquetry decoration of arabesque ornament in light wood. The upper part, closed by a door inset with a mirror, framed with fluted pilasters and panels of inlaid ornament, contains a cupboard and shelves, in which the architectural motive suggested in the decoration of the exterior is cleverly repeated. The lower part, with slope front and drawers, is fitted with a central cupboard flanked by drawers and pigeon-holes. The whole is surmounted by a pediment with carved scrolls and shield. This piece of furniture is of unusual importance from more than one point of view. It is a distinguished example of English furniture of the early part of the 18th century marked by high quality of workmanship. The fact that it bears the signature of the maker (inlaid on the inner surface of the door) makes it of particular value as a record, for it was not the usual practice for cabinet-makers in England to sign their furniture. Two other signed examples of the work of Samuel Bennett are known, one of which further shows that he lived in Monmouth Square, London. The fine proportions of the details and the restraint and good taste of the ornamental details give it special value as an example for students.

Journal of the Royal Society of Arts

No. 3,737. VOL. LXXII.

30 JUL 192

FRIDAY, JULY 4, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, [illegible]

NOTICE.

EXTRA MEETING.

Wednesday, July 2nd, 1924; Mr. Alan A. Campbell Swinton, F.R.S., late Chairman of the Council, in the Chair.

A paper on "Results obtained over very long distances by Short-wave Directional Wireless Telegraphy, more generally referred to as the 'Beam System,'" was read by Senator Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., a Vice-President of the Society.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The One Hundred and Seventieth Annual General Meeting for the purpose of receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments during the past year, and also for the Election of Officers and New Fellows, was held in accordance with the By-Laws on Wednesday, June 25th, at 4 p.m. The Right Hon. Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, in the Chair.

The Secretary read the notice convening the meeting, and the Minutes of the last Annual General Meeting held on June 27th, 1923.

The following candidates were proposed, balloted for, and duly elected Fellows of the Society:—

Allen, John Scott, Lismore, Ireland.
Blake, Captain Sir H. Acton, K.C.M.G., K.C.V.O., London.
Cawston, Frederick Gordon, M.D., B.Ch., M.R.C.S., L.R.C.P., Durban, South Africa.
Coriell, Louis Duncan, Baltimore, U.S.A.
Cowasjee, Bomanjee, London.
Dalrymple, Col. Sir William, K.B.E., London.
Daniell, Major John Alan Le Norreys, Sudbury, Suffolk.
Dixon, Edward, London.
Durran, William, London.
Freudenthal, Louis Edwin, B.S., Las Cruces, New Mexico, U.S.A.
Frost, Captain Frederick James Tabor, Ramon F. Castro, Argentine.
Gurtu, Raj K., Cawnpore, India.
Ibbotson, Herbert J., Johannesburg, South Africa.
Jenkins, Arnold, Worthing.
Longman, Charles James, M.A., J.P., London.
Mattocks, Captain F. S., R.E., Quetta, Baluchistan, India.
Oxley, Oswald John Philip, Durban, South Africa.
Raju, M.G., L.M.E., Guntur, Madras, India.
Redmayne, Sir Richard Augustine Studdert, K.C.B., M. Inst. C.E., London.
Redwood, Robert, London.
Rummel, G. Albert, Cincinnati, U.S.A.
Shepherd, William Thomas, M.A., M.Sc., Ph.D., Washington, D.C., U.S.A.
Wright, Robert William, London.
Young, Walter J., C.B.E., Adelaide, Australia.
Zaharoff, Sir Basil, G.C.B., G.B.E., D.C.L., Paris.

The Chairman appointed Mr. Charles J. Innes-Baillie and Mr. Robert J. Money scrutineers and declared the ballot open.

The Secretary then read the following

REPORT OF COUNCIL

1.—Ordinary Meetings.

For his inaugural address Lord Askwith selected the subject of "Exhibitions"—a subject on which he was specially qualified to speak by former experience as Head of the Exhibitions Department of the Board of Trade. There can be no doubt that the idea of Industrial as well as Fine Art Exhibitions originated with the Society, for from 1761 onwards they organised numerous exhibitions, culminating in the Great Exhibition of 1851. After giving a history of International Exhibitions from that date up to the present time, Lord Askwith discussed the main principles on which exhibitions should be conducted, and concluded by outlining the principal results which might be hoped for from the British Empire Exhibition, 1924.

M. Edouard Belin, the distinguished French electrical engineer, read a paper, illustrated by numerous experiments, on "Téléphotographie, Télautographie, Télévision." In 1907 he succeeded, by means of appliances based on the use of selenium, in transmitting by telegraph a picture from Paris to Bordeaux. The result, however, was not quite satisfactory, as the outlines were considerably blurred; and he then adopted a new process, based on the use of gelatine bichromate. Details of the apparatus and method were explained and a satisfactory picture was transmitted across the lecture room. Specimens of "télautographie" were also shown, demonstrating the possibility of sending messages in a person's own handwriting, or in shorthand, or in such character as Arabic or Chinese. With regard to télévision, M. Belin stated that certain results had been obtained by means of appliances based on selenium. A great deal more work will, however, have to be done before télévision can be regarded as beyond the experimental stage.

In his paper, "Forgeries of Ancient Stained Glass," Mr. J. A. Knowles described various methods by which such forgeries may be produced and detected. As the habit of paying large prices for old glass is of comparatively recent years, the practice of making forgeries for profit would appear to be a modern growth. The person who suspects a forgery should devote his attention to the materials and the technique. The constitution of glass and of enamels has, of course, varied greatly from time to time, and so have the methods of the artists: if, therefore, one finds a piece of work in the style of the eighteenth century on a piece of glass of the fourteenth century, it may quite possibly turn out that the whole was made in Germany in the late nineteenth century. Mr. Knowles discussed the subject in considerable detail, and brought together a quantity of fresh material which will be of great interest and value to the connoisseur of stained glass.

Sir Henry Gauvain read a paper on "The Effect of Sun, Sea and Open-air in the Treatment of Diseases," in which he described the work conducted at the Lord Mayor Treloar Cripples' Hospital at Alton and Hayling Island. Although the value of the sun as a healing agency has been recognised instinctively from early times, it is only within the present century that its effects have been the subject of careful scientific study. The work was begun independently by Rollier in Leysin and Sir Henry Gauvain himself. Quite astonishing cures have already been effected, and it seems probable that further research will before long open an entirely new chapter in therapeutics. It has already been found that exposure to various kinds of light enormously increases the bactericidal powers of the blood. Further investigations are being made in this direction, and if the results so far observed are confirmed, a new weapon will be placed in the hands of the physician, the power of which in the treatment of disease bids fair to be of epoch-making importance.

Dr. Arthur William Hill, in his paper "The Work of the Royal Botanic Gardens, Kew," gave a brief history of the famous gardens, and some account of the work of its chief directors, such as Sir William and Sir Joseph Hooker, Sir Joseph Banks, Sir William Thistleton-Dyer and Sir David Prain. This was followed by a description of the work now carried on at Kew, which is of an astonishingly varied nature. Botanists trained at Kew have gone out to all parts of the world and made known the resources of the Gardens, and the result is that at Kew advice is sought not only from every part of the British Empire, but from every country where an interest is taken in botany, whether theoretical or practical. Enormous help has been rendered in this way to industry and commerce. To quote two instances, the Para rubber industry of the East, and the cultivation of cinchona in India, Ceylon and Jamaica both owed their origin and success to Kew.

Among the many and various duties of H.M. Office of Works, not the least important is the preservation of ancient monuments and historic buildings. A paper on this subject was read by Sir Frank Baines, in which he defined the principles followed by H.M. Office of Works in this branch of their work. He drew a careful distinction between "preservation" and "restoration," and held that it was the duty of his department to preserve, not to restore, the monuments and buildings handed over to their charge. A vast amount of preservative work has been carried out in recent years by H.M. Office of Works. Sir Frank Baines described a great deal of this with the aid of a very beautiful series of slides, especially notable among which were the roofs at Westminster Hall, and Hampton Court Palace, and the exceedingly successful treatment of Dryburgh Abbey.

In 1908 Mr. G. Albert Smith read a paper on "Animated Photographs in Natural Colours," when he described the process which subsequently became well known under the name "kinemacolor." In that process three lenses were at first employed (and subsequently two); but although these were placed as close together as possible, they necessarily took three pictures which differed very slightly from each other. When these were superimposed there was a resultant "fringing" of colour. Since then considerable developments have taken place, and it is now possible by the invention of a new lens to take two identical snapshots at once. A description of the lens was given by Mr. Albert Smith. The process is known as "Cinechrome." It was employed for the purpose of taking films of H.R.H. the Prince of Wales's tour in India and Burma, and the results as shown at the meeting were generally considered to be extremely striking and successful.

"The Earthquake and the Work of Reconstruction in Japan" was the title of a paper read by Mr. Iyemasa Tokuwaga. Although he had not himself been an eye-witness of the calamity, Mr. Tokuwaga was enabled from official reports, letters from friends in Japan and other sources, to present a vivid account of the havoc wrought by the earthquake and the subsequent conflagration and tidal waves. He also exhibited a series of cinematographic films; the first of these showed Tokio before the earthquake, the others gave impressive pictures of the enormous fires which raged for many days, and of the utter devastation left behind by perhaps the most appalling natural catastrophe of which we have any record.

Public attention has frequently been drawn in recent years to the destruction wrought by the death-watch beetle in the timber roofs of some of our finest and most beautiful buildings. Westminster Hall and Hampton Court are two of the best known instances that have suffered from this cause, but there are cases all over the country where buildings of extraordinary interest are perishing from day to day. Professor H. Maxwell-Lefroy, who has devoted much time to studying the life-history of the beetle and the best methods of attacking it, pleaded for a systematic standardisation of our knowledge on the subject, and for a careful research as to the treatment to be adopted. It is a curious fact that in a good many cases where roofs have been attacked by the beetle, after some time the attack seems to have ceased automatically. If one could discover the conditions which have led to this state of things, one might be able to find out further how these conditions might be produced.

A few years ago there were imported into this country between 40,000 and 50,000 tons of rubber in excess of our normal requirements, and those interested in the industry have been anxious to find new uses for this excess production. A paper on the subject was read by Mr. P. J. Burgess. By the direct use of latex, which has come into vogue during the last five years, it has become possible to employ rubber in the manufacture of waterproof papers, mill-boards, artificial leather, etc., and the growing popularity of crepe rubber for shoe and boot soles has accounted for a certain amount of the excess production; but all these together will not do a great deal to remedy the troubles of the rubber growers, who are looking for new uses, or great extension of old uses, for this material, and Mr. Burgess thinks that their best hope lies in the extended employment of rubber for road surfaces.

Every year about half-a-million children are thrown out of our elementary schools on to the labour market, and they have to sort themselves as best they can to the posts that are available. Naturally this is a very difficult matter, and frequently square pegs try to settle into many round holes before they find a resting place into which they can fit their angular proportions. The National Institute of Psychology has for some time been busy devising and practising tests which may assist in determining the occupations for which persons are most suited. Dr. Charles S. Myers, the Director of the Institute, in his paper, gave an account of some of these tests, which have been applied with considerable success. It is interesting to note that a good deal of work on these lines has been conducted in the United States, Spain, Belgium, Switzerland, Germany, Japan and elsewhere.* In Berlin the movement is supported financially by the Trades Unions, who believe that the tests will assist them in keeping "duds" out of the Unions.

Although a communication on the subject of quartz fusion was submitted to the Paris Academy of Science in 1839, it is only within very recent years that the utilisation of this material has been placed on a commercial basis. Sir Richard Paget, in his paper "The History, Development and Commercial Uses of Fused Silica," gave an interesting historical account of the early work done by various experimentalists, including Sir Charles Parsons and Professor C. Vernon Boys, and of the present state of the industry. Fused silica has several important properties which render it extraordinarily useful in operations conducted at very high temperatures. Its co-efficient of expansion is extremely low, its softening point is very high, it is as hard as hard glass, and its crushing strength is very great. With these qualities there is obviously a wide field for the utilisation of fused silica; but Sir Richard Paget's audience seemed to be greatly astonished by the variety and size of the appliances which he was able to exhibit at the meeting, especially by a large flask-shaped vessel with a capacity of 170 gallons.

Over a million subjects of the British Empire fell during the Great War. Their graves form a girdle of honour round the world. The cemeteries in which they lie are stretched through France, Belgium, Switzerland, Italy, Macedonia, Gallipoli, Syria, Palestine, Egypt, Mesopotamia, East Africa, China, Australia, New Zealand, Canada and back to the United Kingdom. The care of these has been undertaken by the Imperial War Graves Commission, whose Vice-Chairman, Sir Fabian Ware, described in an eloquent paper the steps which are being taken to render them worthy resting places of our immortal dead. Some of our best known engineers and architects have devoted themselves to the task of making these burying grounds permanent and artistic, whilst an army of gardeners is still at work adding to the honoured graves the beauty of lawns and appropriate flowers. Boundless care has been spent not only on the general features of the cemeteries, but in the smallest details of the inscriptions on the graves; and it must be some consolation to those who are left to mourn that the names of their dead are preserved in so much honour by the country which they died to defend.

The vital importance of timbers to many branches of industry was brought home to most of us during the War; but those whose duty it was to consider questions of forestry had long before this been growing anxious as to possible sources of supply for our ever-increasing requirements. Countries which used to export timber to us in large quantities are beginning to find that they have no more than enough for their own needs; and when one hears of single mills in the United States that consume daily sixty acres of timber one begins to realise that the prospect of a world shortage is no mere nightmare fantasy of the forester. It is, therefore, of extreme importance that we should take stock of the resources at our disposal, and this was done, so far as North America is concerned, by Mr. R. L. Robinson. In view of the fact that the United States are rapidly coming to require for their own use all the timber that they can grow, Mr. Robinson urged (1) that we ought to pay more attention to the forests in our own tropical colonies, where we can find good substitutes for hard woods at present obtained from America, and (2) that in this country we should go forward with our forest policy, in full confidence that it will prove a sound national investment.

In his paper on "The Fishing Industry and its By-Products," Mr. Neal Green urged the further application of science in studying various kinds of fish and in developing the sources of their supply. Comparatively little has been done in this direction, and in view of the difficulties of securing control where so vast and turbulent a factor as the sea is involved, it seems rash to hope at present for great developments on these lines. Certain experiments dealing with the transference of young fish to the Dogger Bank, where they developed rapidly in weight and quality, have, however, proved encouraging, and Mr. Neal Green seemed disposed to hope for further success on these and similar lines. He also foresaw a time when improved methods of refrigeration would bring the fish of the South Seas within the reach of European markets. In connexion with fishery by-products the application of science has already been well proved. Fish meal is being produced in ever-increasing quantities and being used with ever-increasing success in the feeding of farm-stock, chickens, etc., whilst excellent glues, isinglass and other materials are being recovered from the waste of the fish.

A special interest was lent to Sir Lynden Macassey's paper on "London Traffic" by the strike of omnibus and tramway men, which was only settled on the eve of the meeting at which the paper was read. Sir Lynden pointed out that it was the Great Exhibition of 1851 which forced on public attention the deplorable conditions then existing in regard to the streets of the Metropolis, and an agitation was started which finally led to the appointment of the Metropolitan Board of Works. Many of the road improvements of the last century could be traced back to the 1851 Exhibition, and the author asked whether the British Empire Exhibition of this year would give a similar impulse to public opinion. The Royal Commission on London Traffic, of which Sir Lynden was Secretary from 1903-7, made an exhaustive enquiry into the whole subject and presented an illuminating report. In his paper the author emphasised the inherent difficulties of the situation, examined the broad principles underlying the remedies proposed by the Commission, and finally examined the London Traffic Bill, now before Parliament, with a view to ascertaining how far it harmonises with the recommendations of the Commission.

While communication with the London Docks by water and railways is good, the roads connecting them with the Metropolis are deplorable. Particularly is this the case with the Victoria Dock district, and with the latter-day increase of motor traffic the drawbacks have become more and more apparent, until there is now a crying need for reform. With the totally inadequate accommodation provided by the existing roads, traffic is held up, and workmen proceeding to the docks are so delayed by the swing-bridges that they often lose a whole day's work. Sir Henry Maybury, in his paper, "The Victoria Dock District and its Roads," pleaded for a scheme of wide new roads capable of bearing the traffic of to-day without congestion. The cost of his proposals he placed at £2,000,000 to £3,000,000, and as it is not likely that this could be borne by the local rates of a poor district, he urged that the scheme should be regarded as an all-London task. Seeing that the London docks are in reality the gateway to the Empire, there seems to be ample justification for his proposal.

Mr. F. Hope-Jones, in a paper entitled "The Free Pendulum," described his very beautiful invention by which it is possible to measure time with a precision never before obtained. The apparatus is extremely delicate and complicated, and it is impossible to explain the mechanism in a few sentences, but the general idea is this: by means of a "slave clock" the pendulum of the "master clock" is freed from all interference, that is to say, it has nothing to do but to swing. The impulse is uniform; it is delivered at or about zero; it is extremely small in quantity, and is imparted at regular intervals of thirty seconds. The pendulum swings in a vacuum, which eliminates all barometric considerations, and the clock is erected in a room kept at a constant temperature.

Any invention which assists navigators either of ships or aircraft to ascertain their exact position must obviously be of great importance as tending to secure the safety of life and property. In foggy weather it is often impossible for days on end to make reliable observations. In these circumstances the use of wireless must be an enormous relief to the navigator. Dr. J. Robinson, in his paper, "Wireless Navigation for Ships and Aircraft," described various systems (including his own) whereby signals are transmitted from direction-finding stations. It would appear that far greater advantage is taken of these aids to navigation in America than in this country. In the approaches to New York Harbour alone there are far more stations than in the whole of England.

In his paper, "Furs and the Fur Trade," Mr. F. C. Ingrams gave a résumé of the history of the fur trade, which is obviously one of the oldest trades in the world. An interesting feature of the paper was the list of names of furs, now obsolete, which were in use in the Middle Ages, such as lettice, miniver, lucerne, pampilion, strandling, etc., all of which the author had identified with the greatest care. Towards the close of the paper Mr. Ingrams gave a number of statistics from which one can form a very good idea of the size and importance of the trade at the present day. At the last London fur auctions there were offered over four-and-a-half million musquash pelts, nearly two-and-a-quarter million skunk, over a million squirrel, a million opossum, and over half-a-million Persian lamb. Mention was made of the growing industry of fox farming; in 1922 there were 977 fox farms in Canada, with a total of 24,163 foxes.

Sir William Pope, who delivered the seventh Trueman Wood Lecture, selected as his subject "The Outlook in Chemistry."

The first part was devoted to summarising the principal developments which have taken place during the last twenty-five years in physical science, and the profound effects which they have produced in modifying our theories of chemistry. These changes would appear to call for corresponding modifications in our educational methods, which are still too apt to cling to the watertight compartments into which science has been divided for so long. The conclusion of the lecture contained an earnest plea for collective effort in the application of science to industry. In the coal tar industry, the gas industry, and various great manufactures, proof has already been given of the great results that may be achieved by "team work"; and Sir William urged the need for large and comprehensive plans involving much experimental work in order to provide the vast amount of precise data essential to the application of chemistry to technical ends.

"The Position of the Arabs in Art and Literature" was the title of a paper by Mrs. Arthur McGrath (Rosita Forbes). As one who has travelled extensively in known and unknown parts of Asia and Africa Mrs. McGrath has a wide and profound knowledge of the Arabs and their arts. These are very varied, and include architecture, wood carving, ceramics, miniatures, ivories, carpets, stuffs, arms, bronzes, gold and silver work, enamelled glass and illuminated manuscripts. Mrs. McGrath gave an admirable summary of the principal characteristics of Arab art, and she then passed on to discuss Arab literature, which she described as one of the richest in the world.

II.—Extra Meetings.

In addition to the Ordinary Meetings, three extra meetings were arranged during the session. At the first of these, which had to be held before the opening of the session, Dr. C. E. K. Mees described the Kodascope, an instrument devised by the Kodak Company to enable amateurs to take cinematograph films. The apparatus is on a considerably smaller scale than that used by professional cinematographers, and is comparatively inexpensive. Several films were taken at the beginning of the meeting and exhibited in the hall an hour later. The results were admirable; and Dr. Mees expressed his belief that, with the help of this instrument, cinematography would be enabled to benefit in the future by the work of the amateur, just as its sister art, photography, had benefited in the past.

Mr. G. M. Booth, in his paper, "The Amazon Valley and its Development," gave an interesting account of the greatest of all rivers, its fauna, flora, and the possibilities of development in its basin, which is as large as the whole of Europe. The interest of this paper was greatly increased by a fine collection of specimens illustrating the resources of the Amazon, which was on view in the library from April 4-18th, and was visited by a large number of persons.

Mr. T. Thorne Baker, who had previously given two excellent papers before the Society, read a third entitled "Photography in Science, Industry and Medicine." His demonstration of the extent to which photography is used as an aid to science will probably come as a revelation to most people. The spectroscopic camera, or spectrograph, is invaluable as a means of rapid chemical analysis, especially as it indicates exceedingly minute quantities. One of the most recent inventions is a photo-micrographic apparatus by which magnifications of 25,000 diameters can be obtained. The use of X-rays in medicine and surgery, and also in such cases as detecting flaws in metals and other materials is growing day by day, and with the rapid advances in the technique of photography, they can be so employed with ever-increasing advantages. Mr. Thorne Baker, in his comprehensive review, gave an illuminating account of the many directions in which photography is now being applied to scientific purposes: perhaps one of his most striking instances was a cardiograph recorded in a consulting room half-a-mile from where the patient lay.

III.—Indian and Dominions and Colonies Sections.

The two sections of the Society each provided seven excellent meetings and, owing to additional dates in the present session not being available, some further offers of papers had to be deferred or put aside. As it was, the number in both sections was larger than usual, while the standard has probably never been higher.

The papers contributed to the Indian Section were, in chronological order, as follows:— (1) "The Indian Ordnance Factories and Indian Industries," by Brigadier-General H. A. Young; (2) "The

Survey of India," by Colonel H. L. Crosthwait; (3) "Salt Manufacture in India," by Sir Richard M. Dane; (4) "The Progress of Co-operative Banking in India," by Mr. Otto Rothfeld; (5) "Chemical Research in India," by Prof. Jocelyn F. Thorpe; and (6) "The Art of the Pāl Empire in Bengal," by Mr. J. C. French. The annual Sir George Birdwood Memorial Lecture, founded in 1919 by the friends of that remarkable man to record his long and devoted services to the Society, especially the Indian Section, was delivered by Mr. William Foster, Historiographer to the India Office, his subject being "The Archives of the Honourable East India Company."

The following were the papers read in the Dominions and Colonies Section:—(1) "The West Indies," by Viscount Burnham; (2) "Empire Settlement," by the Agent-General for Ontario, Mr. W. C. Noxon; (3) "The Commercial Future of the Backward Races," by Mr. F. W. Walker; (4) "Empire Oil: Progress of Sarawak," by the Hon. T. G. Cochrane; (5) "The Geology and Mineral Resources of Cyprus," by Prof. C. Gilbert Cullis; (6) "The Mandate System and the British Mandates," by Sir Frederick Lugard; and (7) "The Mineral Wealth of the pre-Cambrian in Canada," by Dr. C. V. Corless.

The paper of General Young, though mainly historical, dealt also with some problems of great immediate importance, such as the development of Indian industries, now occupying so much attention, a task for which his long and varied experience eminently fitted him. For close upon thirty years he was connected with the ordnance factories of India, and first as Deputy Director of the Department and then as Director had much to do with the valuable military assistance which that country was able to give the Empire in the Great War. It is moreover to the credit of General Young and his predecessors that the general record of the ordnance factories of India is scarcely less renowned in peace than in war, for they can claim to have been the pioneers of modern industrial developments in that country, and must, in General Young's opinion, be used in the same way to the fullest extent to secure progress on sound lines. He does not think that complete "Indianisation" is possible in the near future, or, indeed, that it will be achieved "till a generation of educated Indians arises, trained in mechanical and engineering sciences, experienced in subordinate management and having the power of studying and of assimilating the industrial progress of other countries."

Many Fellows of the Society will remember the paper a valued ex-Chairman of the Council, Sir Thomas H. Holdich, read eight years ago, "Romance of the Survey of India." Colonel Crosthwait began his paper by modestly expressing inability to "emulate the charming and picturesque language with which his former chief habitually adorns his addresses." His own purpose, he explained, was to give the Society an idea of how the geographical survey of a vast country is carried out; how its maps are made; the nature of the scientific work undertaken by the Survey of India, in short, to describe in outline the many enterprises with which that great organisation is concerned. He conveniently divided the work of the Department under three heads:—1. Geodesy; 2. Topography and the drawing of the "fair map"; 3. The reproduction and printing of the map. Regarding the future of scientific operations in India, he thinks that even in these days of financial stringency there will probably not be much difficulty in getting funds for map-making. "Let us hope," he said in conclusion, "that no effort will be spared to continue the world-renowned scientific work of the Survey of India, the foundations of which have been so firmly laid by Everest, Walker and Burrard."

In a comprehensive paper on "The Manufacture of Salt in India," Sir Richard M. Dane took, as the text of his survey, a remark appearing in a pamphlet published in 1884 for the International Health Exhibition and the Royal Society of Arts, that "the salt produced in India whether from washing salt-soil or from the mines in the Salt Range in the Punjab or from the evaporation of sea-water on the coast was, and is, still of an inferior character, more or less dirty in colour and containing from 10 to 12 per cent. of impurities." The statement, so far as Punjab rock-salt is concerned, is, Sir R. Dane said, incorrect. Much of the salt made in Rajputana also is of very good quality and in some places in Sind perfectly pure naturally-formed salt can be collected. It is, however, the case that, except in the north-west, India is not well provided with good salt, and the salt made from sea water by solar heat on the coasts of Bombay and Madras is not as good as salt made by the same process in other countries. As regards the supply of salt in the future, Sir Richard approved of measures taken in the Bombay Presidency by the late Governor, Sir George Lloyd, but advanced the opinion that real efficiency cannot be secured without much greater specialisation in production than has hitherto been considered needful. A supply sufficient in 1881 for a population of 253,000,000 is obviously inadequate for one of 318,000,000, and it is not desirable that India should be dependent to so great an extent upon foreign sources. According to Prof. Rushbrook ("India in 1923") the Government of India propose to provide against any possible failure in Upper India by doubling approximately the annual output from the Punjab mines and Sambhar. So far as the mines are concerned, Sir R. Dane commended this policy, but for reasons he gave he submitted that as regards Sambhar the case is not so clear. The formation of a strong Salt Department appears, he said, to be necessary. Preventive work might be left to the Provincial Excise establishments, but if an adequate supply of good salt at reasonable prices can be assured, he would radically alter the penal provisions of the law and no longer treat as a criminal offence the manufacture of inferior salt for domestic consumption.

In 1917 Mr. Atul Chandra Chatterjee, who for some years previously had filled the office of Registrar of Co-operative Societies in the United Provinces, read a paper on the development of banking and thrift in India. The object of Mr. Rothfeld's paper dealing with the same subject was not, however, to dwell upon the achievements of the village credit society as such, but to present a picture of what has been done by the co-operative movement in the narrower sphere of real banking and especially with the more important application of co-operation to deposit banking in the modern sense. Twenty years ago the mere conception of money in this sense hardly existed in India. Small banking facilities are a primary need of advancing India, and co-operation seems predestined to undertake the duty of supplying such facilities, as is evidenced by the marked progress made in Bombay. The urban banks of the Western Presidency include institutions which, in Mr. Rothfeld's opinion, can face comparison with any similar institutions in any part of the world. One encouraging feature to which Mr. Rothfeld called special attention is the expansion in the use of cheques, stimulated as it had been by a notable concession of Government. Cheques of members of societies are exempted from stamp duty up to a value of 20 rupees. Mr. Rothfeld also referred *inter alia* to the influence of the banks in reducing rates of interest even among money-lenders, an influence of immense value for the prospect of the countryside. As to the future of co-operation, he notes that "with the growing spirit of national feeling and the corresponding gain in self-respect," the number of workers, especially among young men, is noticeably increasing. As regards co-operative marketing, a point touched upon by the Secretary of State for India in the discussion, Mr. Rothfeld was able to say that real progress had been made in his Presidency although it was still only a thirtieth of what it ought to be.

The Indian Industrial Commission which was appointed in 1916 and reported in 1918 included in its many weighty recommendations, the establishment of a service dealing with chemistry, and, as part of the scheme, the formation of a Central Research Institute under the Government of India. The earliest outcome of the Report was the appointment of a strong Committee to formulate proposals for the organisation of the new service and equipment of research laboratories. Professor Jocelyn Thorpe, author of the able and lucid paper dealing with this subject, was appointed Chairman of the Committee and spent several months in the country obtaining an insight into the actual conditions. One effect of his extended tour was to convince him that the Provinces would have nothing to do with the idea of a central research institute as originally proposed, but insisted upon each province having its own research institute. This modification was accepted by the Committee, with the proviso that each Provincial institute confined its activities to its own local immediate industrial needs, leaving a central institute under the Supreme Government to carry out those fundamental researches which underlie the industries of the country as a whole. The selection by the Commission of Dehra Dun for this purpose was endorsed by Professor Joyce's Committee. With regard to the proposed Chemical Service the lecturer dwelt on the use that it would be in not only providing employment for chemists, but in raising the standard of teaching by absorbing a constant stream of recruits from the University laboratories. The general desire of young Indians for Government employment, with which they are often reproached, he suggests is due, not so much to a desire to obtain "soft jobs," as to a lack of stable conditions, the absence of secure tenure, and the impossibility otherwise of gaining posts yielding an assured income. He sees no reason why recruitment to the new service should not in the near future be wholly Indian.

The interest of the concluding paper in the Indian Section, "The Art of the Pāl Empire in Bengal," which was read by one who has studied the subject on the spot, Mr. J. C. French, lies in the fact that it illustrates a period in Indian Art never before dealt with in Europe. The paper is particularly noteworthy because at the period referred to Bengal under the Pāl dynasty was the chief power in Northern India, and the term "Empire" is, therefore, not inapplicable. It is curious to think that Bengal did not again occupy a similar position until after the Battle of Plassey in the eighteenth century. Oriental art is attracting a steadily increasing amount of attention and its affinity with the latest manifestations of modern art is not unworthy of notice.

Almost the only restriction attached to the annual Sir George Birdwood Lecture is that it must deal with one of the many Indian subjects in which he was interested. Mr. Foster decided on "The Archives of the Honourable East India Company" as the subject of the discourse he was invited to deliver. Previous lectures in the series, he reminded the audience, recalled to our memories Sir George Birdwood's affection for the peoples of India and the services he rendered to that country both in the promotion of its industrial arts and in securing a proper appreciation of indigenous artistic skill alike in painting, sculpture and architecture. It was his (Mr. Foster's) privilege to refer to another field of inquiry to which the many-sided genius of Sir G. Birdwood paid no small amount of attention, with results that still claim our gratitude. His investigations in the seventies of last century contributed largely to the creation, in 1884, of a Registry and Records Department at the India Office, whose accumulation is the second largest in England, approaching the Public Record Office itself in range of subjects. The Department also provides better material for the history of India than can be found in any Indian Record office, as well as containing masses of information about other parts of the Empire and of various Asiatic countries such as China, Japan and Persia. One of the excellent illustrations exhibited on the screen showed the earliest known marine insurance policy, dated 1657. Until two years ago it was believed that a policy of 1681, preserved at Lloyd's, was the oldest in existence. Mr. Foster was able to announce that the British-Indian archives are being increasingly utilised by Indian historians as well as by students of our own race. Sir George Birdwood would have asked no better reward for his labours upon the archives of the Honourable East India Company than that they should form a fresh and durable link between the two countries, India and Great Britain.

In the spring of last year Viscount Burnham visited the West Indies and his statesmanlike and eloquent paper afforded a further proof of the active interest he has since taken in the British islands which form our oldest group of Colonies. In discussing the problems he so carefully studied on his instructive tour, he quoted a Jamaica saying, that the people receive everybody well except their Governors, and he thinks that if such appointments were subject to confirmation by a Cabinet Committee, as in the case now of conferment of titles and honours by the Crown, some disappointments might be more easily avoided. He holds that the representative principle should be applied to the more important islands "instead of always trusting to what Bismarck called the 'spirit of the green table' for the pure—and it is pure—officialism of Downing Street is undoubtedly out of date." He put forward a plea for the constitution of the office of High Commissioner for the British West Indies, the holder to rank immediately after the High Commissioners for the self-governing Dominions, and to be at once a political envoy and a commercial agent. From the commercial point of view alone such an official seems to be needed. When a West Indian merchant or planter makes a proposal involving the assistance of British capital, he is met, said Lord Burnham, by our banking houses with the reply, "Why try to make a British company when you can get the money so much more easily in New York ?" Lord Burnham also urged revival of the wholesome and historic principle of virtual representation in the Imperial Parliament in the persons of members of the Associated Chambers of Commerce of the British West Indies and the West India Committee.

Under the Empire Settlement Act of 1922, the sum of £3,000,000 per annum is available for fifteen years to assist in peopling the empty spaces of our Oversea Dominions with the right sort of settlers selected from members of our own race. The enterprising Province of Ontario, so efficiently represented by Mr. Noxon as Agent-General in this country, was the first to avail itself of the facilities thus afforded, and it was appropriate, therefore, that he should be invited to tell the Society something about the work that is already being accomplished under the aegis of the Oversea Settlement Committee. Since the passing of the Act the Home Government has entered into agreements with various Oversea Governments by means of which many persons have been already successfully settled in suitable localities, in addition to which certain of the Oversea Governments have schemes of assisted passages of their own. Up to October last the amount spent by the British Government in this way was some £400,000, and the migrants helped numbered 37,295. Both Mr. Noxon and the Chairman of the meeting, Lord Airlie, laid stress on one feature of the Settlement Committee's work, namely, juvenile migration. In some parts of the Empire schemes are being promoted for the migration and settlement of boys from public and secondary schools, an experiment that will be watched with interest.

In his paper on "The Commercial Future of the Backward Races," Mr. Walker gave an interesting account of an organisation initiated by himself on business lines seventeen years ago, when he was a missionary in Papua. The enterprise appears to have met with no little success and might, it is suggested, be equally successful elsewhere if conducted in the same spirit. Apart from the moral and material improvement of the natives, the advantages to be derived are, it is claimed, (1) an abundant supply of raw material from the tropics, (2) the opening of new markets for home manufactures, and (3) a happy and prosperous people, who will become a strength to the Empire.

Considerable interest was aroused by the paper of Mr. Cochrane on the latest addition to the Empire's petroleum resources by the acquisition of the Sarawak oil-field. Although only fourteen years have elapsed since the discovery there of oil in commercial quantities, the new industry has made great strides, the output during 1923 being about 560,000 tons. Amongst British oil-producing countries Sarawak four years previously occupied fifth place; to-day, as Mr. Cochrane observed, it can claim to be by no means a bad second, the lead, of course, being held by Burma with its many years' development. Lord Bearsted, who presided over the meeting at which the subject was discussed, expressed his belief that Sarawak would prove to be a "wonderful field," and in view of that country's immensely important geographical position, he urged the inconceivableness of our ever allowing it to fall into enemy hands. In the course of a weighty speech, his Lordship, as one who has made the development of oil in the British Empire "almost the passion of his life," uttered the strongest possible protest against that development being attempted by Governments. He said he saw, with dismay, the association of the Australian Government with the British Government in regard to Papua and New Guinea. "Hundred of thousands of pounds had been spent and no result obtained."

In 1878 Cyprus came under British administration, though it remained Ottoman territory and its inhabitants Ottoman subjects. The entry of the Turks into the Great War as the allies of the Central Empires resulted in the annulment of the agreement effected by Lord Beaconsfield, and since the end of 1914 the island has been a British Crown colony. This transformation, Prof. Gilbert Cullis pointed out in his admirably comprehensive survey, carried with it extended responsibilities on the part of the Imperial Government, and in order that the well-being of the people of Cyprus may be promoted a knowledge of the new dependency's potentialities has become more than ever desirable. One of the steps taken by the Colonial Office was to commission Prof. Cullis to visit Cyprus for the purpose of reporting upon its cupriferous deposits, and he was thus afforded a unique opportunity of exploring the country and of acquiring a first-hand acquaintance with its general geology and mineral resources. In concluding his paper he expressed the opinion that another branch of the public service in Cyprus, having the functions and discharging the duties of a Geological Survey and Department of Mines, might with great advantage be added to the local existing administrative machinery.

In the introduction to his fine paper on the Mandatory principle and the British mandates, Sir Frederick Lugard welcomed the opportunity afforded to him of addressing the Society and, through the Society, the public at large, on this subject; for, as he remarked, though the British Empire holds nine out of the fourteen mandates and has incurred responsibility for an additional million square miles and some eight million people, less attention seems to have been devoted in this country to the theory and application of this novel experiment in International Law and its present and future problems than has been evoked in the United States, which holds no mandate at all. The Mandates Commission, he suggested, should, in course of time, become a valuable body, whose task is to promote co-operation—which may extend beyond the frontiers of the mandate territory—and to eliminate friction while fearlessly exposing any manifest breach of the mandate. The system, in short, stands as an international acknowledgment that civilisation must be made to mean something higher to the Powers in their dealings with the backward races than the aims and methods of the development syndicate or the assiduous cultivation of new wants to afford markets for commerce. The Chairman of the meeting, Lord Milner, said it seemed to him likely that the mandatory system, so far from obtaining greater extension, was likely, as time went on, to be rather contracted and to prove in many cases a mere transitory stage. Nevertheless, it remained even in its curtailed and more or less mutilated form—he meant as compared with the original big conception—a very important factor in the international situation.

Canada, Dr. Corless reminded us in his long overdue paper, dealing with the mineral wealth of the Dominion, is a country of vast dimensions, seventy times as large as the motherland. It is, therefore, not surprising that the relative mportance of the natural resources of such a huge country is being revealed but slowly even to Canadians. Still less is it to be wondered at that the relative extent of those resources is almost unknown in Great Britain. Considering all the facts, the vast pre-Cambrian area he so fully described may, Dr. Corless said, in time become the greatest and most permanent source of supply of the world's needs in the precious metals.

IV.—Cantor Lectures.

Two short courses of Cantor Lectures, consisting of two lectures each, were delivered before Christmas. The subject of the first was "The Cultivation of Cocoa in British Tropical Colonies." Mr. Samuel Henry Davies, the lecturer, discussed the questions of suitable soil and climate, the selection of seed, the planting out of seedlings and the use of windbelts—a very important point, as the countries most suitable to the cultivation of cocoa are those which are specially liable to hurricanes. The principal diseases and the methods of fighting them were dealt with, as were also the questions of collecting and breaking the pods, fermenting, drying and shipping the beans. The whole subject is one of rapidly growing importance, as will be seen from the fact that the world consumption of cocoa has risen from 100,000 tons in 1900 to 411,000 tons in 1922.

Professor Aldred F. Barker delivered two lectures on "Recent Progress in the Wool Industries." Fresh from a tour round the world he was able to describe with first-hand knowledge the latest developments in breeding in connexion with Australian and Cape wools, and to discuss Colonel Stordy's experimental researches with reference to the Alpaca and Vicuna in Peru—researches of which a preliminary account was given to the Society by Colonel Stordy himself in 1920. Attention was also drawn to Mr. Stefansson's suggestion for the employment on a large scale of ovibos fibre in textile manufacture. In his second lecture Professor Barker reviewed the recent improvements in the principles of the manipulating of the raw materials, and recent mechanical developments, and he concluded an extremely interesting course by sketching the prospective distribution of the wool industry.

Dr. Eric K. Rideal, who gave a course of lectures on "Applications of Catalysis to Industrial Chemistry" in 1921, gave another course of three lectures on "Colloid Chemistry." In the first he discussed the nature of colloids, and the problems of surface tension and absorption. The work of Hardy and Langmuir was described, and the most recent theories of lubrication were expounded. The second lecture dealt with suspension colloids, peptisation, protection and precipitation. Various industrial processes were discussed, such as peat-drying, the condensation of fumes, and the use of powdered fuels. The subject of the third lecture was the emulsion colloids, their preparation and stabilisation. Attention was given to the chemistry of coal tar disinfectants, milks, various greases and soaps. In conclusion, the permeability of membranes was considered, and the lecturer expressed his belief that the progress of industrial chemistry will depend increasingly on the advances made in this important branch of physico-chemical investigation.

Mr. E. V. Evans delivered three lectures under the title "A Study of the Destructive Distillation of Coal." In the first he discussed the various factors which cause wastage of therms in the forms of gas, and the general principles on which depend high yields of gaseous therms. In the second he dealt with the process conditions affecting the distribution of therms in the forms of gas and tar, and proceeded from this to consider the chemistry and economics of tar cracking. In the third lecture he spoke of the general trend of developments in carbonising processes, and concluded with a discussion of the de-ashing of coal and other factors tending to increase the value of the therm in the form of coke.

V.—COBB LECTURES.

In his course of three lectures on "Certain Fundamental Problems in Photography," Dr. T. Slater Price discussed the chemistry of colloids, with special reference to their division into suspensoids and emulsoids. The latest investigations as to the effect of gelatine on reactions involved in making a photographic emulsion were described, and the progress in producing photographic emulsions generally was considered. The course of lectures was particularly valuable as giving an authoritative account of the recent progress made in our knowledge of the cause of the sensitivity of a photographic emulsion.

VI.—MANN JUVENILE LECTURES.

Under the Dr. Mann Trust three Juvenile Lectures were delivered in January. The first two, on "Fire and Explosions," were given by Professor W. A. Bone. He gave a short historical account, with numerous experiments, of the work of various chemists from Jean Rey to Henry Cavendish, who have investigated the nature of fire, and subsequently he described the work of Davy, George Stephenson, Faraday, Smithells, Bunsen, and Welsbach. The lecture was fully illustrated with explosions which were much appreciated by the audience.

The Third Juvenile Lecture was given by Mrs. Julia Henshaw, who chose as her subject "Among the Selkirk Mountains of Canada (with Ice-Axe and Camera)." Mrs. Henshaw has travelled much in Canada, and she has brought back with her many lantern slides of little known places. A number of these have been painted by herself with the greatest taste and skill, and her slides of the flora of the Selkirk Mountains are of quite remarkable beauty.

VII.—ALBERT MEDAL.

The Albert Medal of the Society for the current year has been awarded by the Council, with the approval of the President H.R.H. the Duke of Connaught, to H.R.H. the Prince of Wales, K.G., "in recognition of Services rendered to Arts, Manufactures and Commerce, as President of the British Empire Exhibition, and by his visits to the Dominions and Colonies."

VIII.—MEDALS FOR PAPERS.

Eleven medals have been awarded for the papers read before the Society during the current session—seven for papers read at the ordinary meetings, two for those read in the Indian Section, and two for those read in the Dominions and Colonies Section.

The awards are as follows:—

Papers read at the Ordinary Meetings :—

SIR FRANK BAINES, C.V.O., C.B.E., Director of Works, H.M. Office of Works, "The Preservation of Ancient Monuments and Historic Buildings."

SIR RICHARD ARTHUR SURTEES PAGET, Bt., "The History, Development and Commercial Uses of Fused Silica."

MAJOR-GENERAL SIR FABIAN WARE, K.C.V.O., K.B.E., C.B., C.M.G., Vice-

Chairman, Imperial War Graves Commission, "Building and Decoration of the War Cemeteries."

FRANK HOPE-JONES, M.I.E.E., Vice-Chairman, British Horological Institute, "The Free Pendulum."

BRIG.-GENERAL SIR HENRY P. MAYBURY, K.C.M.G., C.B., Director-General of Roads, Ministry of Transport, "The Victoria Dock District and its Roads."

T. THORNE BAKER, "Photography in Industry, Science and Medicine."

MRS. ARTHUR MCGRATH (Rosita Forbes), "The Position of the Arabs in Art and Literature."

Papers read in the Indian Section :—

BRIGADIER-GENERAL H. A. YOUNG, C.I.E., C.B.E., late R.A., Director of Ordnance Factories, India, 1917-21, "The Indian Ordnance Factories and Indian Industries."

SIR RICHARD M. DANE, K.C.I.E., Commissioner, North India Salt Revenue, 1898-1907 ; Foreign Chief Inspector, Salt Revenue China, 1913-18, "Manufacture of Salt in India."

Papers read in the Dominion and Colonies Section :—

C. GILBERT CULLIS, D.Sc., M.I.M.M., Professor of Economic Mineralogy, Imperial College of Science and Technology, "A Sketch of the Geology and Mineral Resources of Cyprus."

THE RIGHT HON. SIR FREDERICK LUGARD, G.C.M.G., C.B., D.S.O., D.C.L., LL.D., British Member, Permanent Mandates Commission, League of Nations, "The Mandate System and the British Mandates."

For many years it has been the practice that no medals should be awarded to members of the Council, or to readers of papers who have previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers :—

G. ALBERT SMITH, "Cinematography in Natural Colours—further Developments."

ALAN A. CAMPBELL SWINTON, F.R.S., late Chairman of the Council, "Personal Recollections of some Notable Scientific Men."

C. E. K. MEES, D.Sc. (Director of Research and Development, Eastman Kodak Company), "Amateur Cinematography."

The Council desire, however, to express their high appreciation of these papers.

IX.—SWINEY PRIZE.

In accordance with the provisions of the will of Dr. George Swiney, the prize bearing his name was duly awarded in February last, on the eightieth anniversary of the testator's death. Dr. Swiney died in 1844, and in his will he left the sum of £5,000 Consols to the Society of Arts, for the purpose of presenting a prize, on every fifth anniversary of his death, to the author of the best published work on Jurisprudence. The prize was to be a cup of the value of £100, and money to the same amount; the award to be made jointly by the Royal Society of Arts and the Royal College of Physicians.

A meeting of the adjudicators of the prize was held on February 11th, 1924, under the presidency of Lord Askwith, Chairman of the Council.

The adjudicators received a report from the joint Committee of the Royal Society of Arts and the Royal College of Physicians, recommending that the prize should be awarded to Sir Paul Vinogradoff, for his work, "Outlines of Historical Jurisprudence."

On the motion of the Chairman, seconded by Sir Humphry Rolleston, President of the Royal College of Physicians, it was thereupon unanimously resolved : "That the Swiney Prize be adjudged to Professor Sir Paul Vinogradoff, F.B.A., for his work, 'Outlines of Historical Jurisprudence.'"

X.—ANNUAL COMPETITION OF INDUSTRIAL DESIGNS.

In the last Report of the Council it was announced that an Annual Competition of Industrial Designs would be instituted open to two classes of candidates, (*a*) students of British schools of art, and (*b*) any British subjects. Arrangements were made to hold the first competition in June, 1924, and by the kindness of the Director of the Victoria and Albert Museum, the Council have been granted the use of the Museum for this purpose.

In order to add to the attractiveness of the competitions it was decided to offer awards in the form of diplomas, medals, money prizes, and, if funds permitted, travelling scholarships. An appeal for assistance was issued, with the gratifying result that at the first competition the Council were enabled to offer over £1,000 in prizes and travelling scholarships.

This year the competition is being held in the following sections : Textiles, Furniture, Book Production, Pottery and Glass, and Miscellaneous. The particulars and conditions of the competition were issued in December, 1923, and were very widely circulated. Great assistance was also rendered by the Press, both technical and non-technical, in making known the competition.

The last date for receiving entries was June 9th. Over 1,300 designs have been received from about 500 competitors.

It has been the aim of the Council and of the various committees appointed by them to carry out this competition, to ensure that any designs approved by them should bear evidence that the designers possess not only exceptional artistic ability, but also a sound and practical knowledge of the materials and processes of their trades. The various committees consist mainly of representatives of important manufacturing and commercial firms, and the judges nominated by them will not be likely to overlook the question as to whether a design submitted is suitable or not for the materials for which it is intended.

After the awards have been made, it is intended to exhibit a number of selected designs at the Victoria and Albert Museum, and subsequently at suitable centres outside London, where they will be brought to the notice of manufacturers likely to be specially interested in them.

As soon as the Judges have completed their work it is proposed to issue a full report on the competition, which will be published in the *Journal* and circulated widely among manufacturers and competitors. It is hoped that this report will be of great service to young designers and to the industries concerned. The judges will be able to criticise the work submitted, to show wherein it is defective, either from the artistic or practical point of view, and to point out the lines along which development is to be encouraged.

XI.—EXAMINATIONS.

The number of entries for this year's examinations again constitutes a record. For the April series the figure was 27,273, for the June series 43,838, making a total of 71,111, as against 68,241 in 1923.

In order to show their growth the figures are given for the last six years, for 1914, which was then the record year, and also for 1916, which shows the effect of the war on the entries:—

Year.	Number of entries.
1914	37,974
1916	25,968
1919	34,173
1920	54,010
1921	55,182
1922	60,331
1923	68,241
1924	71,111

The examinations are held in most of the principal cities and towns of Great Britain and Ireland, and in nearly all cases are conducted and supervised by the Local Education Authorities, to whom the Society is greatly indebted for the efficient manner in which these duties are carried out.

There were 363 Centres for the April Examinations, and 347 Centres for those in May and June. The County of London, where the Examinations are under the control and supervision of the London County Council Education Committee, is only reckoned as one Centre, though under this head are included entries from nearly two hundred Evening Institutes, Polytechnics, Proprietary Schools, etc. The number of entries for the County of London was 3,468 in April, and 13,147 in May and June.

The liberality of the Worshipful Company of Clothworkers has enabled the Council, as in past years, to offer the usual silver and bronze medals. These medals are very highly valued by the successful candidates, and they contribute not a little to maintain the high standard of the examinations.

The results of the First Division of the Examinations, held in April, have already been communicated to the candidates, and those of the June Division will be announced as soon as possible.

A report giving full details of the year's Examinations will be published in the *Journal*, as usual, at a later date.

XII.—ORAL EXAMINATIONS IN MODERN LANGUAGES.

The Oral Examinations are still in progress in various parts of the country. Particulars will be given in the annual report on the Examinations.

XIII.—NEW COUNCIL.

The Vice-Presidents retiring under the ordinary regulations are: Sir Charles Stuart Bayley, Lord Bearsted, Mr. Edward Dent, Lord Montagu of Beaulieu, and Mr. Carmichael Thomas (who is nominated as a Treasurer in place of Lord Blyth). In their places the Council recommend Captain Sir Acton Blake, Lord Blyth, Sir Edward A. Gait, Lord Leverhulme, and Sir Philip Magnus.

The four Ordinary Members of Council retiring are: Mr. Charles Frederick Cross, Sir Edward Davson, Sir Philip Magnus (who is nominated a Vice-President), and Mr. Ernest H. Pooley. In their places the Council recommend Sir Frank Baines, Sir Archibald Denny, Colonel Sir Arthur Holbrook, and Sir Charles C. McLeod.

XIV.—OBITUARY.

The Council have to regret the loss of a certain number of distinguished Fellows who have died during the year.

Sir William Duke was a member of the Council, and Chairman of the Indian Section Committee from 1916 to 1920.

Dr. W. H. Maw had served on the Council since 1911, and was one of the Society's Treasurers at the time of his death.

Sir Henry Evan M. James was for many years a valued member of the Indian Section Committee.

Sir Henry Kimber, who died at the age of ninety, had been a Fellow of the Society for forty-seven years.

Mr. F. T. Waring had been a Fellow of the Society since 1892, and he frequently took part in the discussions.

Among other notable Fellows who have died during the last twelve months may be mentioned Sir John Stewart Clark, Mr. H. S. Freeman, Mr. T. Jenkinson, Mr. W. J. Leonard, Sir Robert Park Lyle, Mr. Paul Gregory Melitus, Mr. G. W. Taylor, Mr. J. H. Tritton, Mr. A. F. Wenger, and Mr. C. J. Wild.

XV.—FINANCE.

At the close of the Council's last Annual Report the hope was expressed that the Financial Statement for 1923 would show a further improvement over that for 1922. It is very satisfactory to learn that this hope has been fulfilled. According to the Financial Statement published in the *Journal* of June 20th, the excess of income over expenditure in 1923 was £1,383 13s. 8d. as compared with £596 17s. 4d., the figure for the previous year. This improvement is due generally to very careful supervision in the case of all matters of expenditure, and specially to the economies effected in the miscellaneous printing of the Society.

While the Council feel that they have good reason to be satisfied with the situation shown by the Income and Expenditure Statement for last year, they would remind Fellows that there remains a considerable deficit to be made up in the Building Fund Account. The cost of purchasing and renovating the Society's House was about £50,000, towards which, so far, nearly £43,000 has been subscribed, leaving £7,000 still to be raised. Many Fellows have contributed to this fund with great generosity, but about *ninety per cent.* of them have not yet subscribed at all. The Council would earnestly appeal to those whose names have not yet appeared in the subscription lists to assist them in clearing off the debt either by subscribing themselves or by endeavouring to secure fresh support for the Society among their friends.

THE CHAIRMAN (Lord Askwith) moved the adoption of the Report, which showed that there was no fault to find with the Society, and that it was continuing in a progressive and flourishing manner. The finances had improved, and the papers and lectures had been of a very high standard. The fact that the proceedings of the Society were published throughout the wide world by means of the weekly journal was fully appreciated by the distinguished people who had read papers before the Society. The Council had under consideration proposals for improving the Journal, which he hoped would be of further advantage to the Society. He also mentioned that the Society had been left a legacy of about £10,000 (the exact amount had not yet been determined) to found a Trust for the advancement of the Science of Navigation and the scientific and educational interests of the British Mercantile Marine.

DR. J. AUGUSTUS VOELCKER said he had much pleasure in seconding the adoption of the Report. He was sure all the Fellows would be struck with the excellence of the papers and lectures provided during the past session. He could assure them that their interests were well looked after, and that the Council in their turn were encouraged by the continued appreciation and support given by Fellows to the Society's work. He referred to the large increase in the number of candidates who had entered for the examinations and to the good work which was being done in this direction.

The adoption of the Report was then agreed to.

THE CHAIRMAN then proposed a cordial vote of thanks to Mr. G. K. Menzies (the Secretary), Mr. S. Digby (the Secretary of the Indian and Dominions and Colonies Sections), Mr. George Davenport (the Chief Clerk), Mr. J. H. Buchanan (the Accountant and Examinations Officer) and to the other officers of the Society for their services during the year. The Secretary's work had been continuous throughout the session, and he was always looking out for opportunities to benefit the Society. Their thanks were also due to Mr. Digby for his remarkable talent in obtaining papers dealing with Indian and Colonial subjects.

Mr. Carmichael Thomas said he had great pleasure in seconding the vote of thanks. They all saw the results of Mr. Menzies' work in the pages of the Journal, and he could assure the Fellows that the Council very greatly appreciated the Secretary's services.

The Secretary returned thanks for this expression of confidence in himself and in the other officers of the Society.

The ballot having remained open for half-an-hour, and the scrutineers having reported, the Chairman declared that the following had been elected to fill the several offices. [The names in *italics* are those of Fellows who have not, during the past year, filled the office to which they have been elected.]

President.

H.R.H. The Duke of Connaught and Strathearn, K.G.

Vice-Presidents:

Sir Thomas Jewell Bennett, C.I.E.
Captain Sir Acton Blake, K.C.M.G., K.C.V.O.
Lord Blyth.
*Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.
Marquess Curzon of Kedleston, K.G., G.C.S.I., G.C.I.E.
Earl of Durham, K.G., P.C., G.C.V.O.
Peter MacIntyre Evans, M.A., LL.D.
Sir Edward A. Gait, K.C.S.I., C.I.E.
Lord Inchcape, G.C.M.G., K.C.S.I., K.C.I.E.
Sir Herbert Jackson, K.B.E., F.R.S.
Lord Leverhulme.
Lt.-Col. Sir Henry McMahon, G.C.M.G., G.C.V.O., K.C.V.O., C.S.I.
Sir Philip Magnus, Bt.
Senator Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.
Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.
John Slater, F.R.I.B.A.
James Swinburne, F.R.S.
*Alan A. Campbell Swinton, F.R.S.
J. Augustus Voelcker, M.A., Ph.D.
Sir Philip Watts, K.C.B., LL.D., F.R.S.
Sir Aston Webb, K.C.V.O., C.B., P.R.A.
*Sir Henry Trueman Wood, M.A.
Sir Alfred Yarrow, Bt., M.Inst.C.E., F.R.S.

Ordinary Members of the Council.

Sir Frank Baines, C.V.O., C.B.E.
A. Chaston Chapman, F.R.S.
Sir William Henry Davison, K.B.E., D.L., M.P.
Sir Archibald Denny, Bt., LL.D.
Sir Robert Abbott Hadfield, Bt., D.Sc., F.R.S.
Rear-Admiral James de Courcy Hamilton, M.V.O.
Col. Sir Arthur Holbrook, K.B.E.
Sir Thomas Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.
Major Sir Humphrey Leggett, D.S.O., R.E.
Sir Charles C. MacLeod.
Sir George Sutton, Bt.
Sir Frank Warner, K.B.E.

Treasurers.

Lord Askwith, K.C.B., K.C., D.C.L.
Carmichael Thomas.

Secretary:

George Kenneth Menzies, M.A.

* *Nominated by H.R.H. the President.*

On the motion of the Chairman a vote of thanks to the scrutineers was carried unanimously.

Mr. Carmichael Thomas proposed a very hearty vote of thanks to the Chairman for his services during the past year. Speaking as a Member of Council of more than twenty years' standing, he said Lord Askwith had proved to be an ideal Chairman. He had gained the respect and affection of all the Members of the Council, and the speaker expressed the hope that in course of time Lord Askwith might be re-elected to the office.

Sir Thomas Jewell Bennett, C.I.E., seconded the motion. The Society owed its wonderful prestige in great measure to the fact that it had always been able to draw upon the most notable men of science and letters and in public life for its Chairmen of Council. Lord Askwith had fully kept up the high standard of those who had held the office in the past, and they were very grateful to him for all the services he had so willingly rendered to the Society.

Lord Askwith thanked the mover and seconder of the vote of thanks, as well as the meeting for the manner in which it had been received. Chairmen of Council held office as a rule, for two years, and at the expiration of that period they retired. He was vacating the post in accordance with the By-Laws with considerable regret, because of his interest in the Society's work. He hoped that next year they would have a Chairman of Council who would bring before them in his inaugural address some interesting matters of which possibly some of them were at present ignorant. He said he could not divulge his name until after the next meeting of the Council.

The meeting was then adjourned.

SOCIAL CONDITIONS IN PORTUGAL.

The first fact which forces itself on the attention of the observer of social conditions in Portugal, writes H.M. Consul at Lisbon, in his recent annual report, is the widespread illiteracy. Three out of four of the population of six millions can neither read nor write. Thus not only are they bookless but even the Press cannot reach them. National schools exist for those who choose to attend—a number which for various reasons, including prejudice and superstition, is very small. From time to time efforts are made to introduce a compulsory system of education—the latest attempt was made in the summer of 1923—but the Bill was shelved.

But though primary education seems to make little or no progress there are other influences tending to develop the mental outlook and character of the people. The cinema, for instance, has become the chief recreation of the humbler town dwellers, to whom—though the popular style of film is, as a rule, not very edifying—it presents scenes and manners of other countries which otherwise could be known to but few.

Another innovation, which is bound to react on the national character, is football. To many thousands of Portuguese youths, football is to-day almost a religion. Not only does it provide a healthy occupation where in many cases none existed before, but it tends to foster the team spirit and sense of fair play which is so valued a social asset in England.

From a material point of view, there is no doubt that the condition of the people as a whole has greatly improved in the past few years, owing to the increase in the level of wages, which have risen considerably more than the cost of living.

THE SILK BREEDING INDUSTRY IN HUNGARY.

The Hungarian Government is taking all possible steps to revive the silk nursery, which was completely destroyed during the communist sway. According to the *Silk Journal*, the breeders receive worms, foliage and written instructions free of charge. In all schools and institutes notices are posted explaining silkworm breeding, and it has lately been decided to show educational films in all cinemas in March and April each year. The Government has also sent out instructors and technical experts to different parts of the country.

It is worth mentioning the Szekszáder Microscopical Institute (possessing about 265 instruments), which supervises the breeding. The butterflies, after laying their eggs, are crushed and tested for bacteria, with the result that the eggs put on the market are faultless and of such good quality that even Japan obtains some of her supplies from Hungary.

As a result of the efforts of the Government, the yearly production has increased since 1919 from 35,000 kilogrammes to 402,000 kilogrammes, and the number of private breeders from roughly 2,500 to 15,000. At present the home demand absorbs all the cocoons; and although to-day Hungary imports a certain quantity, especially from Italy and Bulgaria, for working up, it is hoped that in a few years, with further support from the Government, there will be a surplus for export purposes in the silk trade.

NOTES ON BOOKS.

Rice. By Edwin Bingham Copeland. London: Macmillan & Co., Ltd. 20s. net.

Rice is the world's greatest crop. The normal annual production is estimated by the International Institute of Agriculture at the amazing quantity of four hundred and forty billion pounds of rough rice. It is probably the staple food of the majority of the human race; and the number of cultivated varieties probably exceeds that of all other grains combined.

In view of its immense importance it is extraordinary to find that hitherto rice has not formed the subject of book treatment in any Western language. A great deal has been written about it, but the information is so scattered that it is practically inaccessible to those who require it most. Great credit is therefore due to the author of this work, who, as Professor of Plant Physiology and Dean of the College of Agriculture in the University of the Philippines, brings to the task a ripe scientific knowledge as well as a practical acquaintance with the troubles of the rice cultivator.

In this book of 350 pages, Professor Copeland treats of the whole subject of rice from A to Z. Chapter I gives a concise but adequate account of the botany of the plant. Chapter II deals with climate, soil and water, and this is followed by an extremely interesting chapter on the diseases and pests of rice. Although rice is probably the most widespread of crops, it is remarkable, writes Professor Copeland, " that it has never, so far as we know, been destroyed as an industry of any country as coffee has been wiped out in several, and is not even known to be generally subject to any such serious damage from an enemy as wheat, for example, has suffered from its rust. The explanation is probably not that rice is more immune than wheat, in its nature, though this is possible, but is rather to be found in the different methods of culture. Commonly transplanted, and always harvested by hand where its culture is old and intense, rice has been comparatively easily and naturally guarded against epidemics, by reasonable care and without recourse to any scientific methods, such as disinfection or the use of the enemies of the pests."

In subsequent chapters the author deals with the varieties of rice; rice in the United States, in the Philippines and in other lands; and the uses of rice. He also describes the various kinds of machinery used in rice cultivation, and discusses when it is advisable to employ machinery and when it is better to trust to hand labour.

The text is enriched by twenty-seven illustrations. Of these perhaps the most striking are the frontispiece and the picture facing page 242, both of which depict the "Igorot" rice terraces in Northern Luzon. Here the mountains on both sides of the valley have been carved into terraces, while walls and dams have been built to contain the necessary water. The amount of labour expended on the work is almost incredible, and it is all the more wonderful because it has been carried out by people who in most respects are not very far removed from savagery.

GENERAL NOTES.

The Silk Journal.—It is remarkable that the silk industry, which employs nearly 35,000 workers engaged in the manufacture of silk goods, and a much greater number engaged in the distribution, making-up and ancillary occupations, has existed for so many years without a paper devoted specifically to its interests. That reproach is now to be removed from the industry. The first number of the *Silk Journal* has just appeared, and it is to be published monthly. The editor is Mr. Frank Nasmith, a member of the council of the Textile Institute. The Journal is extremely well got up, it contains a number of excellent articles, and does credit to the enterprise of the editor and to the printers.

Silk Production in the Empire.—Professor H. Maxwell-Lefroy, writing in the *Silk Journal*, states that silk is not now one of the important products of the Empire; the silk, that is the raw material used in the preparing, spinning and weaving factories, in England, that is worn in all parts of the Empire, is, with the exception of part of India's consumption, produced in other countries. In 1913, out of 960,000 lb. of raw silk consumed in manufacture in England, only 25,000 lb. was from Empire sources; in 1922, out of 976,000 lb. (worth nearly £2,000,000) 78,000 lb. was from Empire sources. This condition is not going to remain; silk is being produced experimentally, and in a few years it will be an important production.

State Aid to Sericulture in Algeria.—Renewed efforts are being made to stimulate silk-worm culture in Algeria, writes the United States Vice-Consul at Algiers. The Government will distribute free silk-worm eggs, and the governing board of the botanical gardens in Algiers will attend to the destruction of the chrysalides, and will purchase the cocoons at current prices, owing to the difficulty experienced by small producers in carrying out these operations. The Government will also allow a bounty of 60 centimes per kilo of cocoons in addition to the purchase price.

Coast Erosion.—The Minister of Agriculture, Mr. Buxton, was recently asked in the House of Commons whether any careful yearly record is kept of the effects of coast erosion, so that counteraction may be taken without delay if the occasion warrants it. Mr. Buxton stated that the only information which normally reaches his Department from time to time on this subject is in respect of those areas where there is a drainage authority possessing statutory powers to carry out sea defence works. He added that no direct action is taken by the State for countering coast erosion, and that the Royal Commission, which reported fully on the subject in 1911, suggested that the carrying out of sea defence works was not a matter for public expenditure, and, moreover, found that more land was being recovered from the sea than was being lost.

Profit from Silver Foxes.—The silver fox farming industry on Prince Edward Island (according to the Canadian Official Press Bureau) is now yielding an annual cash revenue of over £400,000 and producing excellent profits for the farmers. Pelts sent from the island to the recent fur auction sale at Montreal realised the highest prices there. Some fine skins obtained as much as £70 to £90. All prices, however, were exceptionally good. Last year about 2,600 animals were sent from the island for breeding purposes to American points alone, and smaller numbers were sent to Scotland and Germany.

Female Labour in Canada.—The "Canada Year Book, 1922-23," shows that in 1891 11.07 per cent, in 1901 12.01 per cent., in 1911 14.31 per cent. of the female population 10 years old and over were gainfully employed—an increase from one-ninth to one seventh of these ages during the 20-year period, a rate of increase, which in view of the labour conditions of the war and reconstruction period will, it is reported, probably be found to have been maintained in the present decade. "It is significant," says the Year Book that among females the age period during which there is a maximum of gainful employment is shown by the census to be that from 15 to 24 years inclusive. Of the female population of these ages 27.78 per cent. were in 1911 gainfully employed, a percentage which fell to 12.14 per cent. for the period 25 to 64 years inclusive. As every employer of female labour knows, the decline is due to the absorption of female labour by marriage and home duties."

Victoria and Albert Museum.—Mr. Eric Robert Dalrymple Maclagan, [illegible], has been appointed Director and Secretary of the Victoria and Albert Museum in succession to Sir Cecil Harcourt Smith, C.V.O., who retires on September 11th. Mr. Maclagan joined the staff of the Museum in 1905 and has been Deputy Keeper, Department of Architecture and Sculpture, since 1921. *The Times* says:—"He has shown in various articles and other publications that he possesses a refined and discriminating taste as well as a profound knowledge of art."

R. I. P.

NOTICE.

INDIAN SECTION.

Monday, 30th June, 1924; Rt. Hon. The Earl of Ronaldshay, G.C.S.I., G.C.I.E., in the chair.

A paper on "The Art of the Pal Empire in Bengal" was read by **Mr. J. C. French, I.C.S.**

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 12th, 1924.

Sir Herbert Jackson, K.B.E., F.R.S., in the chair.

The paper read was :—

PERSONAL RECOLLECTIONS OF SOME NOTABLE SCIENTIFIC MEN.

(Illustrated by photographs).

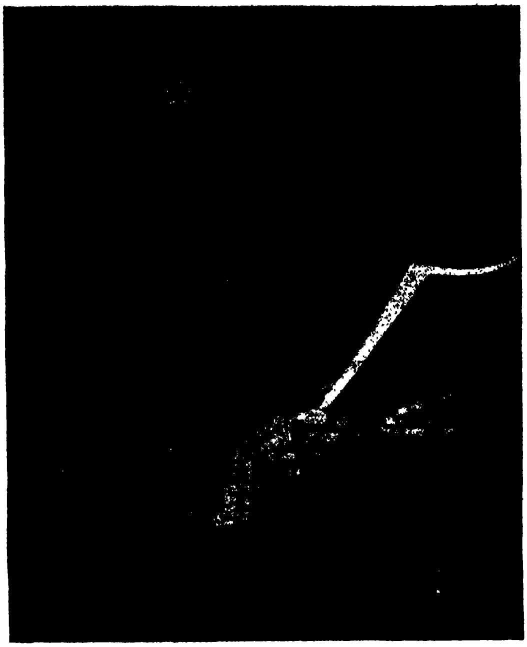
By **Alan A. Campbell Swinton, F.R.S.**

(Late Chairman of Council).

Some years before the war I was giving a Friday evening discourse at the Royal Institution upon Electricity Supply. Some of you may know that the methods adopted at the Royal Institution on Friday evenings are rather peculiar. The Chairman takes his seat before the lecturer enters the lecture hall, but, save that he sits in the Chair, the Chairman takes no part in the proceedings. When the lecturer comes in, as he does when the clock strikes one—the Royal Institution clock is a very special one, inasmuch as it never strikes anything but one—he [illegible] ays immediately followed by the resident Professor, who comes in by another door. The resident Professor for many years was the late Sir James Dewar. On the occasion in question, while we were waiting outside the lecture theatre for the clock to strike, Sir James Dewar said to me, "You see, I am here to do my duty." "What is that ?" I asked. "My duty," he said, "is to see that the lecturer does not run away." "Why," I asked, "has that ever occurred ?" "Oh, yes," he replied, "Professor Wheatstone was left alone on one occasion, and just before the lecture was about to begin he got frightened and ran away and hid himself, and Faraday had to give an extempore lecture in his place."

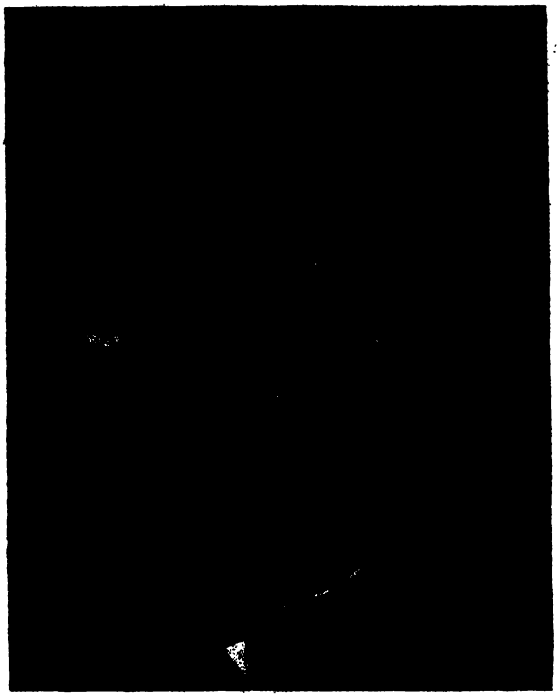
Well, I have had no chance to run away to-night, although I might have wished to do so ; for when this lecture was announced, a very well-known Professor of Chemistry expressed his surprise at its nature, and said that he had no idea that I had any experience of giving lectures of a biographical kind. Well, let me confess at once, I have no such experience, at any rate before an audience like this, and this lecture is an experiment "*in corpore vili*" where this audience are the victims.

The first scientific man I ever met was Professor Huxley, the great protagonist of Darwinism. In 1877 he happened to be sitting on a Royal Commission on Scottish Education with my father, and my father asked him to stay for a few days at my old home at Kimmerghame, in Scotland. His visit caused some considerable stir in the neighbourhood. I can almost remember the actual words of our head gardener, who was a very intelligent individual, when he said he could not understand how Mr. Swinton, a God-fearing man, an Elder of the Kirk, and a member of the General Assembly, could ask to his house such a notorious unbeliever. I remember also that our old Scottish nurse was very much concerned about the visit, and after family prayers, which we used to have every morning, and at which Professor Huxley was present, this dear old lady in a tremulous voice asked me, as I had been kneeling next to the Professor, if I had noticed whether he had joined in repeating the Lord's Prayer. This shows how times have changed, for I do not think that men like Huxley are looked at askance in the same way now.



Lord Armstrong.

It was not until some years later that I met other scientific men. I was apprenticed to Lord Armstrong (then Sir William Armstrong) and in 1882, I entered his celebrated works at Elswick, in Newcastle-on-Tyne. Sir William Armstrong was a very remarkable man. He is chiefly known for his invention of the hydraulic crane, accumulator and other machinery and for the famous Armstrong gun, but he was originally a practising solicitor. He first achieved fame by investigating some curious electrical phenomena which had been observed at Cramlington Colliery, near Newcastle, in which electrical sparks were obtained from the steam escaping from the safety valve. Due to this investigation he invented what is known as the Armstrong hydro-electric machine, and attracted the attention of Faraday, and was elected a Fellow of the Royal Society. He continued, however, in the practice of the law until he was 35 years of age, when he turned to engineering, and started the famous Elswick Works. At a later period, during the Crimean war, his attention having been turned to the very deficient arrangements that then obtained with regard to gunnery, he developed his famous gun. Of course, when I first came in contact with him he was a comparatively old man—72 or 73—but he lived until he was 90 years old, and during the latter part of his life I used to see him fairly frequently, because he took again in his old age to his original electrical hobbies, and I, who lived in London, used to get his apparatus made for him and used to go and see him at his beautiful home, Cragside, in Northumberland. The illustration is a photograph which I took of him in 1891, when he was 81 years of age. I remember him teling me that he had been delicate as a boy, and that when he married, at the age of 25, he could not get any Insurance Company to insure his life because they said he had heart disease. He was very original and precise in his ideas, and on one occasion he told me that he thought all poetry to be poor stuff. He had never received any training as an engineer, and he could not draw at all. When I had the task of getting things made for him it was somewhat of a difficulty for him to describe what he wanted without resorting to drawing, but of drawing he was quite incapable. For an engineer not to be able to draw is certainly very peculiar. He was a great organiser and a shrewd judge of character. Though no mathematician, he had a remarkable faculty for intuitively getting to the bottom of things. He was also a pioneer in many directions. His house at Cragside was one of the first houses to be lighted by electricity, and he also had in



Sir Andrew Noble.

his grounds what I think was the first hydro-electric installation in this country and the first transmission of considerable quantities of electric energy over a fairly long distance.

It was in 1887 that I took the photograph of Captain (afterwards Sir Andrew) Noble, who was Lord Armstrong's right-hand man for many years, and afterwards succeeded him as Chairman of Messrs. Armstrong, Whitworth & Co. Noble was a profound mathematician and a living encyclopedia on all subjects, besides being the hardest working man I ever came across. He must have had a wonderful constitution, as he used to work fifteen to eighteen hours a day; then travel up to London by night and do the same thing next day. Like Lord Armstrong, who received the Albert Medal of this Society in the year 1878, Sir Andrew Noble received the same distinction in 1909. Lord Armstrong used to say that there was only one worse draughtsman at Elswick than himself, and that was Sir Andrew Noble.

I next show a group of scientific men taken by myself at Sir Andrew Noble's house at Jesmond, Newcastle, on the occasion of the Newcastle Meeting of the British Association in 1889. In addition to Sir Andrew himself, it includes Lord Kelvin, Professor Osborne Reynolds, who had a theory of matter to the effect that everything consisted of hard corpuscles, illustrated in the picture by a heap of billiard balls, and Sir Frederick Abel, the well-known chemist, who was one of the inventors of cordite and of the Abel fuse and one of the earliest people to put gun-cotton into practical use. He was a good friend to this Society, and was at one time Chairman of its Council. Another figure in this picture is Sir Frederick Bramwell, who also took great interest in this Society. Again, we have Sir William Abney, the great photographic expert, Sir George Baden-Powell, the elder brother of the founder of the Boy Scouts, and Captain Casella, of the Royal Italian Navy. There are many things that one could say about some of these people.

First of all let me say a few words about Sir Frederick Bramwell. He was a great character, and there are many stories told about him. I was told only the other day that he was the actual inventor of the well-known story which makes one man go up to another and say, "Have you heard? Rothschild has bought the *Times*." "Oh, is that so? What did he pay for it? It must have been a large sum." "Oh no, only 3d." His advice to after-dinner speakers to

Prof. Osborne Reynolds. Capt. Casella. Lord Kelvin. Sir F. Bramwell. Sir G. Baden-Powell.
Sir Andrew Noble. Sir Frederick Abel. Sir William Abney.

"Get up, speak up, and shut up," was at any rate sound. He had an elder brother, Lord Bramwell, a judge, who divided liars into four classes—liars, damned liars, expert witnesses, and "my brother Fred." This recalls the riddle of Biblical connexion that was invented in the early eighties, after a celebrated patent law action, concerning the telephone, at which there was much contradictory expert evidence. "Why did Ananias stand forth?" was the question, and the answer, "Because Bramwell stood first, Thomson stood second, Hopkinson stood third, so Ananias could only stand fourth."

Sir Frederick Bramwell was a great expert witness and he was also something of an actor. On one occasion when it was necessary to his side of the case to prove that a minute was a very long period of time, he suddenly, while giving his evidence, stopped short in the middle of a sentence. Nothing happened, all was silence and one could have heard a pin drop; counsel fidgeted with their papers, the Committee thought that Sir Frederick must have been taken ill; we know how interminable a minute can seem under such circumstances, and when the minute had expired, he merely said, "I have been silent for precisely one minute." It was a very effective way of showing how long a period one minute is. On another occasion he paralysed a cross-examining counsel by saying that he would answer counsel's question, if counsel could tell him what was the distance between Westminster Bridge and Christmas. Another story is this: He was employed by someone on special business and sent in his bill, which the client thought was moderate. This being so, after a time his client employed him again and got a "whopping" bill. Meanwhile, Sir Frederick Bramwell had been elected a Fellow of the Royal Society, and had received the honour of Knighthood, so that when the client wrote and expostulated, Bramwell replied, "You should have noticed those three letters after my name, F.R.S., they mean 'fees raised since' and besides that, you have now got to pay for 'Knight' work."

Bramwell, as can be seen from his portrait, was built on a generous scale with portly dimensions and a very fine presence, hence it was not out of place when someone in proposing a vote of thanks alluded to him as "our worthy member who so fittingly fills and so fittingly fits the presidential chair!"

Next we come to Lord Kelvin, one of the most remarkable men of the last century. The first time I ever met him was when I was taken to see him in his laboratory in 1882, when he had just lighted up his house by electricity. I suppose I must have suggested that electrical engineering might have a great future, and be a good business to take up, but he replied, "Oh no, it will never be more than a plumber's job." And he gave similar advice to other people. Only to-day I was told a story by Sir Joseph Thomson, which rather illustrates the same aspect of his character. Lord Kelvin was asked to join the Marconi Company in its early days, and in telling someone else, he said, "Yes, I have accepted, but I made it a condition that their capital is not to be more than £100,000, because no wireless telegraph company can ever want any more money than that."

It is curious that this great man was not able to foresee any better. Lord Kelvin never read any books, at all events in his later years. He used to get all his information by talking to people. He was a most kindly man. I remember one story about him which was told me by Sir William Ramsay, who was a student in Lord Kelvin's laboratory. On one occasion Lord Kelvin wished to charge up a very large Leyden jar that he had. Now a charged Leyden jar is a thing with which one has to be careful; Lord Kelvin, unfortunately, took hold of the Leyden jar by the knob and charged it up, and after he had done so, he suddenly realised that he now could not put it down. If he had placed it on the floor or on a table he would have received a severe shock, and if he had dropped it he would have smashed it to pieces. I think they had to get a net or something of that kind into which Lord Kelvin was able to drop the Leyden jar, but the spectacle of the great man holding on to the jar of which he dared not leave go must have been a funny one. Lord Kelvin also received the Albert Medal of this Society in 1879.

I will next refer to Alexander Graham Bell, the original inventor of the telephone, which he perfected in 1876. In the United States they always claim Bell as an American, but as a matter of fact he was a Scotsman, born in Edinburgh, in 1847, and as he told me himself, he invented the idea of the telephone in Canada, though he did not get it actually made until he went to the United States, where later, he became naturalised as an American citizen. He was a remarkable old man, and he did other things besides inventing the telephone. As some of you may remember, the phonograph, as originally invented by Edison, in which the sounds were recorded by indenting a piece of tinfoil, was a very crude affair. Bell received in connexion with the telephone a money prize of considerable value, and he told me that he determined to utilise this amount in doing something useful. After consideration, what he set himself to do was to improve Edison's phonograph, and it was Bell, in conjunction with a friend of his called Tainter, who conceived the idea, instead of indenting tin foil, of cutting a record with a sharp cutter upon wax, which is the basis of all modern phonographic and gramophone records. Bell was no business man himself, and I presume that, had he been left to his own devices, he would never have made any money out of the telephone. I do not think he even realised that there was any commercial value in it. He had, however, married a lady who was deaf and dumb; and her father, Mr. Hubbard, was a very clever business man, with the result that Bell's father-in-law, by putting the telephone to commercial use, made a very large fortune, which in time became Mrs. Bell's. Bell, therefore, died the husband of a very rich woman, the money having been made through his own invention, and yet not made by himself. Bell received the Albert Medal of this Society in 1902. I met Graham Bell in London, in 1907, when he sketched for me his recollection of his first telephone. He was a very modest man, and on that occasion he said to me, "I do not pretend to be an electrician, in fact, my friends tell me I could not be one, because if I had been one I should have known beforehand that my telephone would never work."

Mr. Edison improved upon the Bell telephone as far as the transmitter is concerned. When we use the telephone to-day, the receiving instrument which we put to our ears is practically exactly as Bell left it, but the ordinary microphone transmitter is partly the invention of Mr. Edison. Of course, Mr. Edison did more than improve the telephone transmitter. He invented the phonograph, which is a notable achievement, and he was one of the original makers of successful incandescent electric lamps. It is a curious thing to look back now to the early days of the incandescent electric lamp, and to remember how Edison and Swan made filaments out of such an intractable material as carbon. Mr. Edison tried platinum, iridium and other metals, and then he had recourse to carbon. Now, of course, everybody has gone back to the metallic filament. Tungsten in a metallic form, I suppose, was not known in those early days of Swan and Edison.

Sir Joseph Swan was contemporaneous with Mr. Edison—in fact, even before him—in the invention of the carbon filament electric lamp. Perhaps I should say they were neck and neck when it came to commercial lamps, but as a matter of fact it was Swan who showed electric lamps in a lecture at Newcastle four or five years before Edison was in the field, though nothing came of it, and it found no commercial application. Swan was also one of the inventors of the carbon process of photography. He was President of the Institution of Electrical Engineers and received the Albert Medal of this Society in 1906. With his long silver hair, and flowing snowy beard he was a most picturesque person.

David Hughes was one of the original inventors of type-printing telegraphs. The ordinary tape machine at clubs and hotels is very much based on his work. He invented his printing telegraph while in America, but he was a Welshman born in London, and went out to America at an early age. He is usually known as Professor Hughes, but he was a professor, not of engineering or physics, but of music. After having got his telegraph taken up all over the continent, he came back and lived in this country. In 1878 he invented the microphone, and, as we now know, he made experiments in wireless telegraphy some years before the Hertzian waves had been discovered by Hertz. Hughes lived in a small flat off the Tottenham Court Road, and he and his wife—a quaint old couple—lived so economically that I do not suppose they ever spent more than £500 a year. I remember once suggesting to him on a wet night that I should fetch a cab to take him home, and he said to me, "Cab! Oh no, I cannot afford cabs." Shortly afterwards when he died he left something like three-quarters of a million sterling to the London Hospitals. After his death, Mrs. Hughes, who was an American, went back to live in the States, and two or three years ago she died and left her husband's notebooks to the British Museum, which did not quite know what to make of them. Finally, the Museum authorities sent them to me to advise whether they ought to be accepted. I happened to know that Hughes had made experiments in wireless telegraphy which had never been published, and I thought it might be possible to find something in those notebooks. In this I was successful and I told the British Museum that I thought they ought to be preserved, as I found in them a complete account of Hughes's experiments in wireless telegraphy. He had evidently carried on wireless telegraphy up to distances of some hundreds of yards. He had a clockwork apparatus by which he sent wireless signals, and he used to walk down the street with a telephone connected to some sort of cohering arrangement applied to his ear, to see over what distances he could get the signals. He succeeded in obtaining what was actually wireless telegraphy but his ideas about the phenomena were all wrong, because he thought it was a case of electrical conduction through the air. This, of course, was before the date of Hertz's discovery of the electro-magnetic waves called by his name—waves, the existence of which had been predicted by Clerk Maxwell. After perusing Hughes's notebooks it occurred to me that at some time or other he must have possessed a quantity of apparatus, so I enquired as to where these notebooks had been found. I was shown a fearful mass of rubbish in a pantechnicon off the Tottenham Court Road. There were two rooms full of old clothes, old boots and umbrellas, and masses of books and old newspapers. I went to Colonel Lyons, the Director of the South Kensington Science Museum, and he undertook to look through all this, provided if anything of interest was found it was to go to the Science Museum. As a result, a number of Hughes's original microphones and various forms of telephone receivers evidently made with his own hands, and the apparatus with which he had conducted experiments in wireless telegraphy, all in accordance with, and all readily recognised from the sketches in his notebooks, were discovered, and have now been placed in the Science Museum, where they have formed a most interesting exhibit.

It was from the late Sir William Crookes that I had heard of Hughes's wireless experiments, Sir William Crookes having been shown them in confidence by Hughes shortly after the experiments were first made.

Sir William Crookes was a great chemist, and of him, Lord Kelvin once said that he had never known any man start as many scientific hares, meaning that Crookes had originated a great many new ideas in science which others had advantageously pursued. As is well known, he was an early believer and investigator in spiritualism, so much so, that, whereas when he was knighted and he had taken as his motto in connexion with his coat of arms the medieval proverb "Ubi Crux ibi Lux," this being a pun on his own name, some wit at one of the Red Lion dinners of the British Association altered the motto to, "Ubi Crookes ibi Spooks."

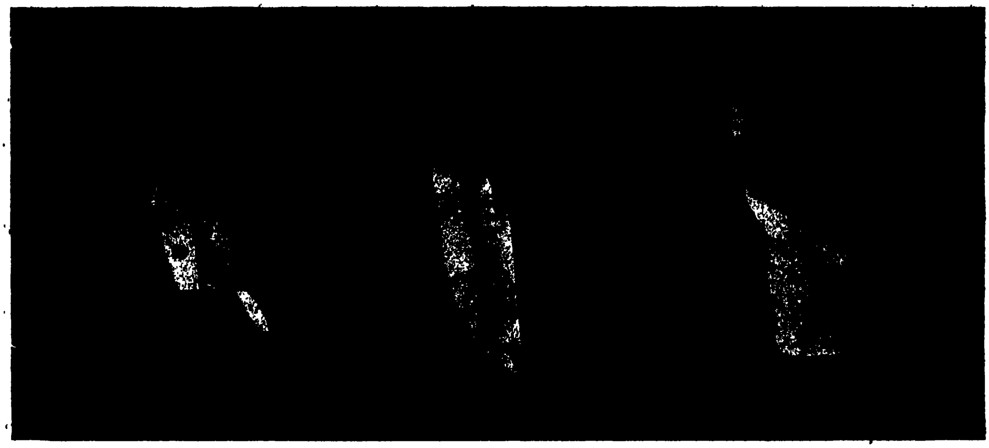
It was Sir William Crookes's investigations into the phenomena of electric discharge in high vacua, and his investigations into what he called radiant matter, that formed the first beginnings that gave rise to all the modern theory concerning the atom. Crookes also wrote a remarkable article for the *Fortnightly Review* in 1892, in which he gave a wonderfully accurate forecast of what might be done in the way of wireless telegraphy by means of Hertzian waves. No doubt, in part, he had got his ideas in this from Hughes's experiments, which, as already mentioned, he had witnessed, but his forecast went a long way beyond what Hughes had done, and it must be remembered that the article was published years before Lodge or Marconi had made any of their earliest experiments.

It was with one of Crookes's cathode ray tubes that Professor Röntgen, in 1895, discovered the X-Rays that are now known by his name. When these rays were first discovered they caused an immense amount of popular curiosity, particularly their property of enabling bones in the living person to be photographed. I possessed an early photograph of this description, the subject being my own hand, which, when the subject was new, interested people very much. I remember going one night to a club which used to meet at the Grafton Galleries on Sunday evenings, and showing the photograph to the late Lord Crawford, who was a well-known scientific amateur. It was the first time he had seen one of these photographs and he was very much interested in it. He told me that the Prince of Wales (afterwards Edward VII.) would be coming to the club shortly and he would like to show him the photograph, as it would be sure to interest him. This he did, but the only remark that the Prince made on being shown this latest scientific wonder were the words, "How disgusting!"

Shortly after Röntgen's discovery of the X-Rays, one of the most curious episodes in the history of modern science took place in France. Professor Blondlot, a well-known professor of Physics at Nancy, who had done excellent work in other directions, announced that he had discovered another and new description of radiation, which he named the N-rays. With these rays, which he stated were emitted by nearly all bodies in a state of strain, he claimed that he could see in the dark, and with them he even professed to be able to produce a line spectrum. Sir William Crookes and others in this country tried to repeat Blondlot's experiments, but no one had any real success. I can well remember my own exceeding disappointment at my failure to obtain any result after prolonged and strenuous endeavours. Sir William Crookes even went out to Nancy specially to see the rays, but came back quite unconvinced as to their existence. However, a number of distinguished French men of science continued to believe in them, and the Académie des Sciences of France solemnly presented Professor Blondlot with a gold medal for his discovery.

Shortly after this Professor R. W. Wood, of the John Hopkins University, Baltimore, came on a visit to Europe and thought he would like to see these remarkable rays. I do not think the sequel has ever been published, but I have it from Professor Wood himself. He went to France and was shown the spectrum of the N-Rays produced by means of a prism. Professor Wood himself could see nothing, but the French scientists assembled at the gathering saw, or at any rate professed to see, the spectrum, and the remarkable thing was that they continued to see it even after Professor Wood, taking advantage of the complete darkness in which the experiments were being shown, had surreptitiously removed the prism out of the apparatus and put in his pocket. Nowadays one never hears of the N-Rays, and I do not think you will even find them mentioned in any modern scientific book. Probably the phenomena were due to some peculiar form of self-hypnotism. No doubt the observers were perfectly genuine, but what they saw or thought they saw was subjective and not objective. Anyway, Professor Wood, by his perhaps rather venturesome action, gave the N-Rays their quietus.

One of the greatest inventions of modern times is the steam turbine, the advent of which has not only revolutionised the generation of electricity on a large scale, but has also revolutionised the propulsion of big ships, rendering possible for the first time such monsters of the deep as the "Mauretania" and the "Lusitania," and such huge war vessels as the "Dreadnought" and her successors. The next illustration is a photograph, taken in 1911 at my house after dinner, by electric light, of Sir Charles Parsons, the inventor of the steam turbine, with the two engineers who did more than anyone else to introduce turbine propulsion into the Navy—Sir William White, who was Chief Constructor of the Navy when, the turbine was first adopted for Torpedo Boat Destroyers and fast cruisers, and his successor as Chief Constructor, Sir Philip Watts, who designed the original Battleship, "Dreadnought," and many other large turbine driven ships of war. In addition to his eminence as a naval architect, Sir William White possessed remarkable powers of exposition both in speech and in writing. He once told me that as a youth he had been driven to take up engineering as a profession by the necessity of earning his own livelihood, but that, if he could have afforded it, he would have preferred to have embraced a literary career. Sir Charles Parsons received the Albert Medal of the Society in the year my photograph was taken, while Sir William White was Chairman of the Council of this Society in 1908-9, and Sir Philip Watts is at present one of our Councillors.



Sir Philip Watts. Sir Charles Parsons. Sir William White.

My last illustration is another photograph, taken in 1912 in my house, of Professor Silvanus Thompson, Sir William Ramsay, and Mr. A. P. Trotter. When Professor Thompson died, in 1916, I contributed to *Nature* an obituary notice which I hope did justice in some slight measure to his untiring industry and his many conspicuous qualities both of heart and head. A few days after the notice was published an old and very well known member of the Athenæum came up to me in that club and said, "That was a nice obituary notice; I hope that when my time comes you will do as much for me." An irreverent friend, to whom I told this said, "You should have replied, 'Well if you want that you had better hurry up, because I am not feeling very well myself'."

Another little story occurs to me with regard to Mr. Trotter. He came one day to lunch at the Athenæum and when he joined me at the table he exclaimed, "I will never again help on anyone with his coat." On my asking why this sudden resolution, he replied, "A few minutes ago I saw an old gentleman in the hall struggling with his coat, so I helped him on with it, when he turned round and said so sweetly, 'Thank you so very much, but I was trying to take it off'."

In the pages of that useful periodical, *Who's Who*, it is common to state the particular recreation to which the various persons of whom particulars are given are addicted. If you look up Mr. A. P. Trotter you will find that he was for many years

Prof. Silvanus Thompson. Sir William Ramsay, Mr. A. P. Trotter,

adviser on electrical matters to the Board of Trade, and that his recreation is now "remembering that he is no longer a Government official."

Thus ends my first experiment in personal biography. I hope that at any rate it has sounded no jarring note.

[A complete list of the photographic portraits, mostly taken by Mr. Swinton himself, that were shown in the lantern at the reading of this paper is as follows :—

Professor Huxley, Lord Armstrong, Sir Andrew Noble, Professor Osborne Reynolds, Captain Casella, Lord Kelvin, Sir Frederick Bramwell, Sir G. Baden-Powell, Sir Frederick Abel, Sir William Abney, Sir Philip Watts, Sir Charles Parsons, Sir William White, Professor Silvanus Thompson, Sir William Ramsay, A. P. Trotter, Professor David Hughes, Sir William Crookes, Sir William Preece, Sir James Dewar, Alexander Graham Bell, Thomas Alva Edison, Sir Joseph Swan, Dr. Anderson, Lord Rayleigh, Sir J. J. Thomson, W. Duddell, Professor Vernon Boys, Arnulph Mallock, Professor R. W. Wood, Sir Alfred Ewing, Sir Dugald Clerk, Sir Oliver Lodge, Senator Marconi, Professor J. A. Fleming, V. Poulson, Professor Pedersen, General Ferrié, George Westinghouse, Colonel Crompton, Professor John Perry, General Sir Ernest Swinton, the Archbishop of Canterbury, Sir William Bragg, Sir Joseph Petavel, Sir Joseph Larmor, J. H. Jeans, Sir Richard Glazebrook, Major A. P. MacMahon, Professor A. A. Michelson, Sir Henry Trueman Wood.]

DISCUSSION.

Dr. W. Rushton Parker said that, as a medical man, he was interested in the lecturer's remarks about Lord Armstrong having suffered from heart disease as a young man, and yet living to the age of 90. A very eminent physician once said in the speaker's presence that when he was assistant physician at one of the leading hospitals, the secretary of the institution came to him one day and was sounded by him and told that he had heart disease. The secretary told his committee of the trouble, and in those days it was thought that if a man had heart disease his days were numbered. Therefore, the committee of the hospital decided to pension him off with a couple of hundred pounds a year, and he lived for 40 years longer. It had occurred to the speaker that frequently too much attention was paid to heart troubles in connexion with longevity. On one occasion he wanted to insure his life, and he had to send in a statement of all the doctors whom he had consulted during the past few years. Having during that period suffered from a disability which was difficult of diagnosis, he had consulted no fewer than 14 eminent medical men within a few months, and with this record in front of them the company would not insure him at any price. But that was 40 years ago and he was now over 70 years of age.

Mr. William Coldstream, I.C.S., retd., said that the name of Mr. Graham Bell had been mentioned as the inventor of the telephone. It was also mentioned that he was a teacher of elocution. The speaker was a young man in Edinburgh about 65 years ago, and took lessons in elocution from the father of Mr. Graham Bell, who was an able teacher.

Mr. William M. Mordey, President, Institution of Electrical Engineers, said that he was able to recall Professor Hughes very well, and particularly his modesty about his work on wireless telegraphy. He showed his experiments to a number of very eminent mathematical physicists and they were puzzled, having no explanation to offer. Years afterwards, when Marconi was in the middle of his great work, the Council of the Institution of Electrical Engineers, knowing as they did of this work done by Professor Hughes, thought it would be a great thing if they could get him to contribute to their Journal some account of his early investigations. The Council deputed Professor Silvanus Thompson and himself to go and see Hughes, and ask him to allow an account of his actual experiments to be published. He discussed the matter for some time, and finally said, "No this young man Marconi is coming over here, he is going ahead, and I am not going to get up and say 'I did it.'"

Mr. R. A-Ababrelton said that the father of Alexander Graham Bell, whose name was Alexander Melville Bell, in addition to being an elocutionist, invented a system of shorthand, which was the first system of shorthand ever published in "Cassell's Popular Educator." The speaker at that time was very anxious to become a reporter and learned that system, but later had to abandon it. He was one of the few people now living who was intimately associated with Sir Isaac Pitman, and he founded the Phonetic Shorthand Writers' Association in 1872, a body which was now called the Incorporated Phonographic Society. He also wished to ask the lecturer a question with regard to the X-ray photograph of the hand, which was said to be the hand of the late Lord Salisbury. He had an impression that that photograph, or a similar one of Lord Salisbury was taken by his son, Lord Robert Cecil, now Lord Cecil, because at the time it was done, he (the speaker), happened to be Private Secretary to the present Lord Salisbury, and he knew that Lord Robert Cecil was very much interested in the taking of these photographs of hands.

Mr. Campbell Swinton said that as a matter of fact he happened to meet Lord Selborne, Lord Salisbury's son-in-law, at a time when everybody was interested in bicycling. The speaker had a very peculiar bicycle which Lord Selborne desired to see, and having looked over the bicycle, he showed him the bones of his hand. A few days later he was told that Lord Salisbury would like to come and see the bones of his hand himself. Lord Salisbury came accordingly, and a day or two afterwards Lady Salisbury also came. He heard afterwards that Lord Salisbury himself had bought an X-ray apparatus for use at Hatfield. But the photograph he had shown of Lord Salisbury's hand that evening was from the speaker's own negative.

Mr. Rollo Appleyard, O.B.E., M.Inst. C.E., said that he would tell them a story relating to Lord Kelvin. Professor Lorentz, who came over from the Continent last year, had remarked, speaking of Lord Kelvin, that Lady Kelvin must have taken great care of him, because at a lecture at the Royal Institution when Sir James Dewar passed round a vessel of liquid air, Lorentz observed that when it was handed to Lord Kelvin, Lady Kelvin caught her husband hurriedly by the arm and whispered audibly, "Don't drink it, William." He had one other story, relating to Sir Frederick Bramwell, a very remarkable man. He had many fine characteristics, and he did everything in the grand manner. He had few enemies, and a great many friends. On one occasion Sir William Preece was taking the chair at a meeting of the Society of Arts (*vide Journal* Nov. 22, 1901, p. 22), when it fell to Sir Frederick Bramwell to propose a vote of thanks. There had been a discussion on high speed railway travel, and Sir William Preece had been remarking that he would not go down to his grave happy until he had travelled at the rate of 150 miles an hour. Sir Frederick Bramwell said that if the Chairman would fall down a coalmine 784 feet deep he would, by the time he had reached the bottom, have attained a velocity of 150 miles an hour, and would certainly go to his grave.

Sir Archibald Denny, Bt., said that a good many years ago he was honoured by being made President of the Institution of Junior Engineers, then a very active Society. It was the greater honour for him because the Senior Vice-President was Lord Kelvin. Lord Kelvin sat next to him at the dinner of the Institution, and was such an exceedingly modest man that in talking to him one forgot his immense ability and reputation. Without thinking about it, therefore, the speaker began a sort of lecture on electricity, and suddenly he realised to whom he was talking, and said, "I beg your pardon, it is I who ought to listen to you, not you to me." "My dear Sir," said Kelvin, "you are quite wrong. Pray go on, go on! that is how I learn things."

The Chairman (Sir Herbert Jackson) said it was a particular pleasure to him to propose a vote of thanks to Mr. Campbell Swinton. He was sure that everyone must have had a very enjoyable evening in listening to Mr. Campbell Swinton's lecture given in so pleasing and interesting a manner. It was a privilege to have had the opportunity of seeing such a number of photographs, nearly all of which had been taken by Mr. Campbell Swinton himself. Mr. Campbell Swinton had always been so thorough in the photographic work he had done; from the first exposure of the plate to the final production of the re-touched negative and the excellent prints, everything had been done by his own hands. He had had this evening time to give them only a proportion of his interesting recollections of the many prominent men of science whom he had known. Not one lecture, but a course of lectures would be needed, but they were all greatly indebted to Mr. Campbell Swinton for what it might be hoped was only an instalment, and for the great trouble he had taken to make his lecture interesting.

MR. SAXTON NOBLE seconded the vote of thanks to Mr. Campbell Swinton, whom he had known for more than 40 years. He had watched Mr. Swinton's progress among these men of wisdom, and had seen him get greater and greater himself. If he had been giving a similar lecture he would have been able to add one more photograph to the collection of great scientific men, namely, that of Mr. Campbell Swinton. He had recalled to their minds many interesting and remarkable men, the sad thing being that such a number of them were no longer with them.

The motion was passed unanimously, and Mr. Campbell Swinton, after acknowledging the compliment, said that for the lantern slides he was very much indebted to the work of his Secretary, Mr. A. W. Langley.

SIR ARCHIBALD DENNY writes:—I should like to add to my remarks the following.

I remember, as an apprentice, hearing about the wonders of the telephone. It must have been about the year 1878, and Mr. Graham Bell's father-in-law was surely in charge by then, for the price of telephones was very high; but I discovered a small workshop in Glasgow where they made the parts and sold them for the purchaser to put together and thus the royalty was avoided.

I purchased a couple and at that time there was no microphone, so far as I knew. I rigged them up between my brother's room and my own and we carried on conversation but the sound was very feeble. I then heard of Hughes's french-nail microphone, of which I made a couple, attached batteries and had very clear and loud conversations.

On my return from London after my college course in 1883, the telephone had made very great progress and it was in the early eighties when I first met Mr. Swinton, who had invented an excellent microphone. We contracted with his company to fit up our offices and they worked admirably. But Mr. Graham Bell's father-in-law again intervened, and after a patent law case which Mr. Swinton lost, we had to deliver up the instruments.

That was the beginning of my friendship with Mr. Swinton, which has endured ever since. He and I well remember the primitive material used in the first development of incandescent electric lighting. The first ships my firm fitted, were the "Arawa" and "Tainui" in 1883-4. The wire procurable would hardly be used for bell wiring now, and all the fittings were on an equally primitive scale, bottom loop lamps, etc., etc.

But this brought me into contact with another of our brilliant young electricians, Mr. Ferranti, as those ships were fitted with two of his ribbon armature alternating current dynamos. It was fortunate they were alternating current as we used single wiring with the skin of the ship as return, and with the inferior wire electrolysis would have set in resulting probably in disastrous fires, had the current been continuous. I need say nothing about Mr. Swinton's later career; it is well known to us all, and he takes his place among "The notable Scientific Men" I have met.

TWENTY-SECOND ORDINARY MEETING.

SEVENTH TRUEMAN WOOD LECTURE.

WEDNESDAY, MAY 21ST, 1924.

SIR HERBERT JACKSON, K.B.E., F.R.S., in the chair.

The paper read was:—

THE OUTLOOK IN CHEMISTRY.

By SIR WILLIAM J. POPE, K.B.E., F.R.S., LL.D., D.Sc.

One of the many useful functions of an ancient Society such as this is undoubtedly that of taking stock, from time to time, of the actual position which has been so laboriously achieved in one or other of the large divisions of pure or applied science. This, I feel sure, is a function which would appeal particularly to the gentleman whose services to science are to be perpetually recalled to fresh generations of students of science by the Trueman Wood lectures. And so, when the Council of the Royal Society of Arts did me the honour of adding my name to the distinguished list of Trueman Wood lecturers, the opportunity seemed appropriate for directing attention more particularly to one specific branch of science in which developments of fundamental importance have quite recently taken place.

I believe, and I think my belief is well founded, that the historian of the future will mark the last twenty-five years as one of the really memorable stages of scientific progress. This brief period has witnessed such a broadening in the scientific outlook on the physical sciences as was never contemplated towards the end of last century: a broadening of the scientific horizon which has forced previously dissonant sections of the scientific community to regard their individual subjects and their main objectives of research from precisely the same standpoint of knowledge and of purpose.

Some obscurity may attach to this problem and a little explanation is desirable. During the nineteenth century the physicist was largely concerned with the determination of essential physical constants and the establishment of the primary relationship between the various forms in which energy manifests itself; it would be difficult to overestimate the intellectual beauty of the work of Thomas Young on the undulatory theory of light, of Clerk Maxwell on the properties of gases or of Kelvin on thermodynamics and the theory of electricity. During roughly the same period the chemist dealt in the main with the material changes brought about in ponderable matter by chemical reaction; Lavoisier's recognition of the elements and his law of conservation of mass, Dalton's establishment of the atomic theory, Frankland's doctrine of valency and his work on organic synthesis and the development of synthetic methods by Perkin, Baeyer, and Emil Fischer, are among the many expressions of genius directed towards purely chemical ends in this particular epoch. But whilst both Physics and Chemistry developed rapidly during the nineteenth century, they developed on what appeared to be quite divergent lines; they had but little community of method, of purpose or of outlook and the chemist was fairly sharply distinguished from the physicist in his mode of attacking a problem and his conception of the meaning of natural phenomena. To the chemist, and especially the organic chemist, the internal constitution of the molecule was the main object of enquiry, whilst the physicist, in his dealings with matter and energy, concerned himself chiefly with extra-molecular happenings; this statement is, of course, not entirely true and it became less true as time passed on, but it is sufficiently accurate as indicative of the diversity of outlook.

During the last twenty-five years this state of affairs has entirely changed; the physicist has developed methods for penetrating into the atoms of which molecules are made up and of elucidating the manner in which the primitive atoms themselves are built up; he has provided simple explanations of many remarkable chapters in chemistry which had been worked out in an almost entirely empirical manner with but little theoretical basis. To-day, Physics and Chemistry are but arbitrary sub-divisions of the great subject of Natural Philosophy; each of their students is a specialist cultivating some minute field of the whole domain but all have the same fundamental conception of the nature of the non-living part of our universe.

It is very interesting to attempt a comparison of the outlook of the chemist of thirty years ago with that of to-day; to make such a comparison involves a brief review of the appearance of the chemical universe then and now, indicating the milestones in the path of progress, and remarking on their significance.

Undoubtedly, the atomic theory enunciated by Dalton in 1803 remained for a century the corner stone of the chemical edifice; in essence, the atomic theory postulates that any chemical element is composed of inconceivably minute and similar particles called atoms and that the atoms of different elements combine in simple numerical proportions to form the ultimate characteristic units, the molecules, of chemically compound substances. It has always seemed to me that Dalton's atomic theory had, at the date of its enunciation, no sure foundation as a logical interpretation of observed facts, though it is naturally impossible to recover precisely the outlook of the chemist a century ago; but whether the atomic theory represented a logical interpretation of experimental observations or whether it expressed an inspiration of a great generalising intellect, it is clear that until a few years ago, the atomic theory remained a theory and nothing more. Ostwald, indeed, made an earnest attempt to present modern chemistry without the aid of the atomic theory and, notwithstanding the recognised utility of the theory as a piece of chemical scaffolding, few held the opinion until quite recently that Dalton's theory depicted an actual state of affairs or supposed it proven that atoms and molecules actually exist. After Dalton came Avogadro, who in 1811 stated the hypothesis that under similar conditions of temperature and pressure equal volumes of different gases contain the same number of molecules. Again no complete logical proof could be given that what was often erroneously described as Avogadro's Law represented an actual state of affairs; nevertheless, Avogadro's hypothesis still stands as the mechanism for rendering intelligible our methods for determining molecular weights.

Other great chemical monuments were raised from time to time; Prout's hypothesis stated in 1816 that the atomic weights are integral multiples of that of hydrogen and become whole numbers if the atomic weight of hydrogen is taken as unity, and Mendeleef's periodic relationship between the atomic weights and physical and chemical properties of the elements, dating from 1869, had a profound influence on chemical thought. Prout's law was temporarily discarded, to be resuscitated a century later in a slightly modified form as perhaps the most striking exemplification of the truth of modern views of the nature of matter and energy; Mendeleef's periodic classification of the elements remained for half a century as a purely empirical justification of a rapidly increasing belief that the elementary atoms are complex structures and that all have a common origin.

With the rapid development of organic chemistry came the enunciation by Frankland of the doctrine of valency with its immediate clarification of our knowledge of the molecular constitution of organic compounds: the introduction of constitutional formulæ by Kekulé gave a directional lead to the work of the organic chemist and this mode of expressing the position relationships between the atoms composing a molecule, based upon the doctrine of valency, has furnished the theoretical network upon which the whole of the vast expansion of organic chemistry has been spread. Again, however, the doctrine of valency represented an empirical conception in the sense that it seemed impossible to give it any theoretical interpretation; at the same time, constitutional formulæ, although continually acquiring a more concrete character from stereochemical work based upon Van't Hoff and LeBel's conception of the asymmetric carbon atom, were commonly regarded as not necessarily of greater significance than expressing a geometrical relationship which was to some extent parallel with the actual state of affairs. Possibly, however, it is not sufficiently grasped by chemists that the introduction of constitutional formulæ, with all their modern consequences, such as the recognition of the existence of definite groups or radicles as component parts of the molecule, constituted an entire revolution in chemical thought. I have myself discussed modern organic chemistry with veterans of before Frankland's day and have been struck by their distrust of the idea that individual atoms of the component elements and specific groupings of those atoms exist as such in the complex molecule; the early conception seems clearly to have been that when two dissimilar atoms enter into combination each loses its identity and becomes, as it were, fused into the other. To our predecessors with such an understanding of chemical combination, the attribution of concrete signification to constitutional formulæ must have been peculiarly difficult.

A multitude of other steps in the development of the chemists' conception of his universe, many of them of importance, might be noted but all are of the same category as the foregoing. The gradually extending chemical outlook of the last century resulted from the exercise of great experimental skill in the collection of observational facts and in the logical generalisation from those facts which yielded the theoretical groundwork of modern chemistry: a wonderfully supple theoretical network was thus built up but it was a network which, in the end, was regarded merely as theory and not as necessarily presenting any real picture of what really exists as causative of the experimental results. This mode of conception has become obsolete during the present century; the atom and the molecule are now known to be realities and much has indeed been disclosed concerning the way in which the elementary atoms themselves are built up. It is interesting to review the manner in which the new outlook has been gained before considering how it affects modern chemistry.

The first step towards a proof of the existence of Daltonian atoms and molecules as concrete entities obviously consists in devising methods for determining some constant relating to their absolute sizes, to the number present in a definite weight of a material or to the mass of an individual atom or molecule; such quantities as these are intimately related and it is convenient, in tracing the development of the subject, to confine attention to but one of them. We may choose for this purpose the Avogadro constant, N, which represents the number of molecules contained in the molecular weight in grams of any species of matter. The mathematical development of the kinetic theory of gases by Clerk Maxwell, Clausius and van der Waals led to a method, based in part on measurements of the viscosity coefficients of gases, by which the Avogadro constant could be calculated; from measurements made on argon, the value $N = 6.2 \times 10^{23}$ was deduced.

Naturally the calculation of this quantity provides no proof of the existence of atoms or molecules because it is based upon the assumption that they do exist; the point which is of importance, however, is that many quite dissimilar methods for arriving at a value for the Avogadro constant are now available and that all lead to values which are identical within the limits of experimental error.

Thus, the botanist Robert Brown noted in 1827 that very finely divided particles suspended in a liquid appear on microscopic examination to be in a state of perpetual agitation and some sixty years later it became admitted that this incessant movement is due to the bombardment of the tiny solid particles by the swiftly moving molecules of the liquid medium itself. If this is the case, the solid particles suspended in a liquid should distribute themselves vertically according to the same law as governs the pressure of the atmosphere at various altitudes; very careful series of observations were made by Perrin of the concentration of uniform particles of gamboge at different altitudes in a thin layer of liquid and it was shown that, interpreting these data as representing an equilibrium condition between the dispersive tendency of the bombardment and the sedimenting effect of gravity upon the particles, a method for calculating the Avogadro constant was obtained. Perrin thus calculated the value $N = 6.83 \times 10^{23}$, which, considering the difficulties of the experimental work, may be regarded as identical with the value calculated from the viscosity of argon. The remarkable nature of this correspondence will be realised when it is noted that a parallel is being drawn between the weight of a gram-molecule of such a gas as hydrogen, namely, two grams, and that of the gram-molecule equivalent of the relatively enormous gamboge particles, which is of the order of 100,000 tons; also that an atmosphere of hydrogen round the earth would have its density diminished to one-half by the action of gravity at an altitude of about 80 kilometres whilst a similar diminution to one-half density occurs at a height of 0.02 to 0.03 millimetre in the suspensions of gamboge.

Again, the late Lord Rayleigh pointed out that the diffusion of light by a gas is due to the gaseous molecules acting as diffracting particles; by an argument which need not now be discussed he traced the blue colour of the sky to this effect and gave a method for calculating the Avogadro constant. This method, applied with modern refinements, has yielded the value $N = 6.54 \times 10^{23}$, again sensibly identical with those furnished by the previously entirely distinct methods.

By far the widest expansion in modern knowledge of the constitution of matter and indeed also of energy is that which has resulted from the study of radio-activity. Apart from the pioneer work on radiant matter by Crookes, the discovery of radio-activity in 1896 by Becquerel and its association shortly afterwards with radium by Madame Curie mark the opening of a fresh chapter in the development of science; so striking has been the broadening of the chemical outlook under the influence of the rapid advance in the study of radio-activity that it may be useful to note a few points of special importance. The most fundamental of these is perhaps the identification by Sir J. J. Thomson of the β-particle as the particle or unit of negative electricity and the demonstration that the α-particle, thrown out during the first stage of the atomic degradation of the radium atom, is the atom of helium carrying one unit charge of positive electricity. Following this as clearing up our ideas on fundamental chemical theory is possibly Rutherford's conception of the structure of the chemical atom; in this it is conceived that the atom consists of a nucleus, minute in comparison with the total volume occupied by the atom, which contains all the particles of positive electricity and, in the case of all the elements but hydrogen, a definite number of particles of negative electricity; the nucleus carries a positive charge equal to the difference between the number of positive particles and the smaller number of negative electrons composing the nucleus. The positively charged nucleus is in electrical equilibrium with the much larger external atomic domain by reason of the presence in the latter of negative particles or electrons equal in number to the nuclear charge. Since the property of mass is chiefly associated with the positive particle of electricity, the electron having a mass only about 1/1800th. as great, the atomic weight of an element becomes very nearly the number of positive particles contained in the nucleus; the atomic weights should thus be practically whole numbers, multiples of the unit atomic weight of the lightest element, hydrogen, in accordance with Prout's hypothesis of 1816. Further, one of the most important characteristics of an element should be the positive charge on the atomic nucleus, or the number of electrons in the external atomic domain; this is the atomic number which was first defined by Moseley, who showed the simple relation which exists between this constant and the spectrum of the light evolved by an element when bombarded by β-particles. As connecting this strange new development of science with earlier knowledge it may be noted that the most accurate method for determining the Avogadro constant depends upon the measurement of the charge carried by the electron of β-particle; Millikan thus determined the value for N as 6.062×10^{23}, a number approximately identical with those previously quoted.

It would be impossible in the limited time now available to submit any adequate picture of the far-reaching deductions from recent work on radioactivity; one or two points may, however, be emphasised. Moseley's work on atomic numbers shows that 92 elements should exist and 87 of these are now known, five being left to be discovered; it indicates that the atomic weights of all the elements should be whole numbers. Rutherford showed that the atomic nucleus, which gives the atomic weight as the number of units of positive electricity included within it, is composed of ponderable positive particles and practically non-ponderable negative particles of electricity, the difference being the atomic number of Moseley; it appears, however, that the atomic nucleus of any particular element can preserve its identity, from the purely chemical point of view, if containing one or more positive and the same number of negative units of electricity less.

The positive charge, the Moseley atomic number, would be thus left unaltered and consequently the identity of the element for purposes of chemical change, should remain unchanged. In accordance with this Aston has found in a large number of cases that the chemical elements are mixtures of atoms of different nuclear composition, although identical as regards the number of negative electrons which compose the outer or chemically active atomic domain. Elements which differ to the extent just indicated in nuclear composition, but which are identical in the number of electrons present in the external domain, have been termed isotopes; it is now known that the atomic weight of each variety of any element appears as a whole number when referred to a particular unit. For a reason which is not yet elucidated, but which is certainly of significance in connexion with our knowledge of the relation between matter and energy, the unit value for the atomic weight of hydrogen has to be selected as 1.008; this unit chosen, the atomic weights of the isotopes of all the elements appear as whole numbers. The empirical deduction of Prout of a century earlier has thus been completely justified. Again, the purely empirical deduction by Mendeleef of the so-called periodic classification of the elements, which has exercised enormous influence in the development of inorganic chemistry, has found complete theoretical justification in the arrangement of the elements in sets of eight in accordance with the system of atomic numbers introduced by Moseley. The deductions drawn by Lavoisier about 1775 which indicated the existence of chemical elements and stated the law of conservation of matter both find theoretical justification in modern conclusions; each chemical element is characterised by the Moseley atomic number and the law of conservation of matter stands subject to the slight adjustment involved in the attribution of an atomic weight of 1·008 to hydrogen. Lastly the atomic theory of Dalton has passed from the stage of being merely a useful hypothesis to that of stating an actual condition of affairs; it is safe to assert that never again in the history of science will the existence of atoms of the elements be seriously challenged.

So far we are on undebatable ground but much more still disputed territory is in sight which will undoubtedly be secured in the very near future. The nature of chemical combination has been long in dispute; the Frankland doctrine of valency has been very fertile as leading to a classification of types of reaction and to a very perfect system of indexing the composition and constitution of chemical compounds. It seems likely that the Rutherford conception of atomic structure, interpreted quantitatively by Bohr and his co-workers, and adapted to chemical mechanisms by men of the Langmuir and Millikan school, will ultimately provide a satisfactory solution of many of the baffling problems now presented by the question of atomic valency.

Yet another remarkable chapter has been recently opened in connexion with the confirmation by contemporary physicists of the singular accuracy of the manner in which chemists long before had interpreted the observed facts relating to molecular constitution. Frankland's doctrine of valency enabled Kekulé about 1858 to develop the theory of the molecular constitution of chemical compounds and later generations of chemists have brought to a great state of perfection the methods for ascertaining the manner in which the component atoms of an organic molecule are joined together. The precision of the synthetic methods of organic chemistry and the striking facts of stereochemistry made it certain that the so-called structural formulæ run closely parallel to the actual arrangement of atoms in the chemical molecule ; at the same time, no independent or more direct confirmation of the substantial correctness of constitutional formulæ was until quite recently forthcoming.

The purely geometrical investigations of Bravais, extended and completed by Sohncke, Schönflies and Barlow, have long since shown that all properties of crystals are consonant with the supposition that crystal structures consist of a regular repetition in space of the molecular units, and consequently also of the atoms which compose the molecule ; any particular plane section of a crystal is thus to be regarded as having a definite reticulated pattern formed by the geometrically regular repetition of component atoms in the plane. It has also been long known that light is diffracted in accordance with well-understood laws from gratings ruled with a large number, say one hundred thousand to the inch, of fine lines. The reticulated pattern of a crystal surface is, of course, far more minute than corresponds to the dimensions just stated and X-rays are of wave-lengths of the order of one-tenthousandth of those of visible light. It thus occurred to Laue in 1912 that X-rays should be diffracted from a reticulated crystal surface in the same way that visible light is diffracted by a grating ; he showed this to be the case and shortly afterwards Bragg founded upon this observation a method for determining the atomic spacings in a crystal by observation of the manner in which X-rays are diffracted from the crystal. Debye and Scherrer showed a little later that massive crystals are unnecessary for the application of the Bragg method but that finely powdered crystalline material can also be used and, in fact, the study of X-ray diffraction from particles of colloidal gold in aqueous suspension has proved that the colloidal particles of this element are crystalline.

The Bragg method has been intensively applied during the last few years and has demonstrated that the constitutional formulæ deduced in an entirely different fashion by the chemist are substantially correct representations of the actual manner in which the atoms are arranged in the chemical molecule.

This necessarily very abbreviated summary of the most important directions of recent progress in physics in so far as they influence chemistry will suffice to prove a quite simple thesis. Whilst the chemist at the end of last century had laid certain theoretical foundations to his science, more particularly those connected with the atomic theory, the doctrine of valency, the Mendeleef classification of the elements, and the vast network of organic chemistry which culminates in the determination of molecular constitution, all these achievements remained as theories or even in part as mere hypotheses until the sudden development of physics during the last twenty years or so transformed them into actual statements of fact. The history of science has never before had to record so dramatic and far-reaching a broadening of the horizon as that which has so recently unified chemistry and physics.

It is doubtful whether the importance of the unifying process which has been carried out so rapidly has been sufficiently realised by the majority of those interested in physico-chemical science, and attention may be directed to one aspect of the question which appears to be relevant.

Whilst the present generation of students is acquiring an outlook very different from that prevalent a few decades ago, our general organisation of teaching methods remains unchanged. The student commences his training in natural philosophy by attending separate courses in inorganic and organic chemistry and in general physics, including heat, electricity and magnetism. But the reason for this early differentiation has now entirely vanished, if indeed, it ever really existed ; all these subjects have the same basis, namely the electronic constitution of matter and energy, and it would seem more rational for the student of natural philosophy to commence his training by a general course for the purpose of elucidating the manner in which all these specialised sections of the one large subject fit into the one great scheme. Students have frequently asked me how to reconcile the tenacity with which a complex molecule of an organic compound retains the perfectly definite arrangement of its component atoms with the view that an atom itself is but a minute nucleus surrounded by a large planetary system of particles of negative electricity in rapid gyration; there is indeed a striking contrast between the rigidity of molecular structure evinced by organic compounds and the apparently flimsy nature of the rotating sub-atomic units from which the whole wonderful edifice is built up. Our teaching methods require considerable adjustment to make them fit the exigencies of the modern scientific outlook.

Probably I have said sufficient to make it clear that the outlook in chemistry is far broader than it was twenty-five years ago; we understand now the meaning of much that had been painfully deduced by generations of careful observers of experimental facts. We may now proceed to enquire what we see in front of us as the result of the wider outlook.

All enquiring minds in science are accustomed to peer into the future in an attempt to discern the directions in which progress is possible; hundreds of imaginative writers have tried to foretell the effects upon human life which will accrue from coming advances in science. In this connexion I desire to submit one ruling principle, a principle which is admirably exemplified by the directions of progress during the present century and which appears to be as yet but ill recognised. The principle is that all scientific prophesy which goes outside what will obviously and logically result from the normal and unsensational development of the existing scientific position is necessarily false. No one in 1900 ever conceived anything so sublime and yet so fantastic as the achievements of the past quarter of a century.

Fears are often expressed that humanity is being impoverished and that posterity will be embarrassed by the rapidity with which our coal and petroleum resources are being consumed; but it is reasonable to presume that long before these potential supplies of energy have disappeared their applications will have become obsolete. Whilst every motive exists for employing our present sources of energy with the maximum efficiency we may safely leave posterity to look after itself with the aid of the scientific heritage with which it will be endowed. The desire to leave coal and petroleum for our successors to consume shows benevolence but appears no more rational than the action of our ancestors in planting England with oaks after the Napoleonic wars so that we might not lack material for the building of battle-ships.

But whilst we cannot see far into the scientific future we can safely foretell certain immediate consequences of the position which chemical and physical science has so lately attained; we are confident that the period, 1925-1950, will be as prolific of discoveries previously unimagined as was the period 1900-1924, and it is futile even to speculate concerning the entirely novel conceptions and discoveries which the next quarter of a century will bring in natural philosophy.

It may be taken for granted that the Bragg method for determining crystal structure, which is still in its infancy and not so far capable of dealing directly with the lighter elements, will provide a means for locating accurately all the atoms present in any molecular complex, either inorganic or organic. This must lead to a great development in our knowledge of chemical structure and should enable the relations between chemical constitution and physical properties, many of which have merely been studied empirically up to the present, to be discerned and stated with precision. Thus, it may be expected that the exact relation between the molecular configuration of an optically active substance and its molecular rotatory power will be ascertained.

Our present knowledge of atomic constitution, with its inevitable developments and its applications to the elucidation of valency, and the elaboration of purely physical methods for determining molecular constitution, may be expected to throw light on an almost infinite number of points of detail in organic chemistry which are still obscure. We may expect to learn the cause of the great stability of the benzene ring, the basic principle underlying the tautomerism exhibited by ethyl acetoacetate and its analogues, the origin of colour in the quinones and why copper of atomic number 29 refuses to form organo-metallic compounds whilst its followers in the series of the elements, namely, zinc, gallium, germanium, arsenic, selenium and bromine, of atomic numbers 30 to 35, all combine with methyl radicles. A quantitative explanation of the energy changes which accompany chemical reactions is to be anticipated. An exposure of the mechanism attending chemical changes in general and of catalytic reactions in particular should be forthcoming; the importance of this latter in connexion with the chemical operations performed by living matter, as bearing upon the utilisation of energy at low potentials for synthetic purposes, can hardly be exaggerated.

A myriad of other obscure questions, which the chemist has already carried nearly as far as his classical experimental methods will permit but which are obviously open to further elucidation in the light of modern methods, will suggest themselves to the intelligent student of chemistry. A danger, indeed, exists that we may encroach on the domain of the imaginative writer of fiction by speculating on the new chemistry which is foreshadowed by Rutherford's transmutation of the elements by the α-particle bombardment of the atomic nuclei and on the complications which will ensue when the several isotopes of many of the elements are available in quantity; although it is often stated that the isotopic varieties of an element will never be isolated in such quantities as are necessary for chemical work yet it is difficult to believe that this state of affairs will long persist. It may be taken for granted that in due course the isotopic chlorines of atomic weights, 35 and 37, will be available in quantity.

Up to the present, I have only discussed the change in the chemical outlook which has resulted from the superb achievements of modern physics, but another and very dissimilar factor has been simultaneously operative. Although the theoretical basis of modern chemistry is of a comparatively simple character, the mass of exact and detailed experimental material laboriously collected and recorded during the last century has made every chemist a specialist; each has ultimately been forced to settle down as a cultivator of one minute patch of the vast chemical domain. A tendency towards individualism has thus been fostered. If we look around, however, we see that a tendency in a contrary direction has become operative, namely, towards combined action for the purpose of producing a definite mass effect. The coal-tar colour industry furnishes an illuminating example of this effect; for many years past a large community of most competent chemical investigators have devoted themselves to the exploitation of the subject of dyestuffs in conjunction with similar bodies of industrial and commercial experts. It cannot be denied that this co-operative effort has produced remarkable results; not only has it, in a comparatively brief span of years, succeeded in dominating one of the oldest and most conservative industries in the world, but it has extended its influence in many other directions. The coal-tar colour industry has, in fact, made itself essential in the production of materials necessary to many other industries, such as those of pharmacy and photography; whilst avowedly commercial in its aims, it has contributed much to the purely scientific development of organic chemistry.

Something very similar has taken place in the electrical industries. Certain of the great research laboratories which form part of a number of electrical firms have made most valuable contributions to the science of pure physics; they can afford a huge expenditure of money for scientific equipment and can attract the assistance of real leaders in contemporary science.

In chemistry itself the advantages of collective effort towards the extension of industrial efficiency is not confined to the coal-tar colour industry; it is seen in the gas industry and in the novel institution, fostered by experience gained during the war, of research establishments each devoted to the development of some specific large branch of manufacturing industry. But if chemical science is to carry its full responsibility in connexion with the amelioration of the conditions of life, far more must be done to ensure efficient team work in developing the applications of chemistry to human interests.

A few examples will illustrate this. The spirochaete of syphilis is susceptible to treatment by certain organic arsenic compounds; knowing this, Ehrlich conceived the idea of studying the therapeutic action of a long series of such compounds for the purpose of selecting the most suitable for the treatment of this disease. He ultimately decided that one particular substance, the so-called 606, was the most satisfactory curative agent from amongst the many which passed through his hands. Since Ehrlich's day other organic arsenic compounds have been introduced for the treatment of this particular disease but all present certain disadvantages and possess certain limitations in efficiency. No thinking person can doubt that if 10,000 compounds, all variously toxic to the spirochaete had been studied, one immeasurably superior to all the others as a curative agent would have been found; this could have been easily done by team-work, and such a discovery would have repaid thousands of fold the original outlay on experimental work. A similar tale has to be told concerning sleeping sickness; Bayer 205 seems to be useful but something much better would certainly have resulted from the examination of some scores of thousands of chemical substances. No such success can be claimed in connexion with the foot and mouth disease, which has cost the country many millions of pounds during the last year, because team action has not been enlisted and consequently absolutely nothing is available for the treatment of this particular malady. A pressing need exists in this country for an organisation with the duty of drawing up schemes for the preparation of long series of related compounds of possible therapeutic value, making the substances and subjecting them to pharmacological investigation.

Let us take another instance. The common and the noble metals have been for centuries the materials of staple industries in many parts of the world; no one metal finds industrial applications in a state of purity but all are used as alloys with other metals. This being the case, and since none of the alloys in general use approaches perfection, it would have been anticipated that by this time we should have been in possession of an elaborate scheme of experimental data which would provide exact information concerning the properties of every possible admixture of one particular metal with one or several other elements; the scheme would, of course, be a very complicated one, but not nearly so complicated nor as difficult and costly to work out as our present system of organic chemistry.

In spite of much pioneer work by Sorby, Heycock and Neville and many others, no such scheme has been evolved; the National Physical Laboratory is now just initiating an experimental investigation for the purpose of studying the alloys of pure iron and chromium and this if successful will be the first occasion on which the systematic study of alloys of pure iron with another pure metal has been undertaken.

Much more might be said on the need for a broader outlook on the applications of chemistry to other sciences and to the arts and on the necessity for the detailed working out of large and comprehensive plans, involving much experimental work of a rather routine or repetitive nature, so as to provide the vast amount of precise data always essential to any application of chemistry to technical ends. Many cases in which valuable results would be thus achieved will occur to anyone familiar with chemical science and acquainted with its bearings upon other branches of knowledge.

DISCUSSION.

THE CHAIRMAN (Sir Herbert Jackson) said that the audience would agree with him that Sir William Pope had delivered a lecture of the first order. He had started by saying that this Society of long foundation was a proper place in which to take stock of the state of our knowledge. The speaker thought that when the lecture came to be printed, and they had an opportunity of reading it, they would be indeed grateful to Sir William Pope for what was an extremely valuable stocktaking survey. He had put shortly—taking less than an hour to do it— the recent and present position in a most illuminating and suggestive way. Naturally when he came to deal with earlier views on crystal structure, in discussing the many suggestions which to some extent foreshadowed the results that had been obtained with X-rays, he omitted his own name; but the learned societies before whom he brought his work knew what Sir William Pope had done on that subject. Then he had taken them through the wonderful and inspiring part of the story, the application of shorter and shorter wave lengths of radiation to the study of the structure of the atom. When they thought of what had been done with the microscope, with the proper interpretation of the scattering of light, with the influence of short wave-lengths in the ultra-violet portion of the spectrum, and then with X-rays, they would realise what a wonderful part light had played in the whole subject, and now that they were beginning to see the work which had been done on the quantum theory of light they had every reason to believe that there would be a still larger part for light to play and more wonderful deductions to be drawn from its action. He often wondered whether the deductions of the old-time workers on the subject of light were quite so empirical as some supposed. Every day that brought further discoveries made him feel more and more respect and admiration for those who went before them and the work they did. Great men of science in different ages had thought alike, and they had only to take recent ideas of light to realise that with something added to

Newton's corpuscular theory they would get near to the theory of the present time which had been dealt with in recent publications. He did not desire to enlarge on Sir William Pope's lecture, and the best thing he could do at the moment was to interpret their feeling of gratitude to the lecturer. But he would like to point out what a very large field the lecturer had taken. Towards the end he spoke at some length on education and industry, although in the early part of his lecture he had dealt with theoretical matters. This would be a truly valuable addition to the Trueman Wood Lectures.

MR. A. A. CAMPBELL SWINTON, F.R.S., in supporting the vote of thanks proposed from the Chair, said that they had all listened to Sir William Pope with extraordinary interest. The speaker did not pretend to be a chemist, but no one could have listened to the lecture without getting a wonderful idea of the progress that had been made in chemical discovery during the last twenty-five years. Chemistry had always appeared to him —knowing very little about it— as a most difficult and complex subject. Perhaps it was becoming more simplified now that the real reasons for the different combinations and the atomic construction were being better understood. It was becoming more a matter of arrangement of particles which anybody could follow, and less a juggling with figures which the chemist might understand but which were Greek to the layman. He did not wish to enlarge on the matter, he would merely endorse what the Chairman had said.

The vote of thanks was accorded unanimously.

SIR WILLIAM POPE, in expressing his acknowledgments, said that he felt with regard to the Chairman that he was treating him with the partiality with which an old friend was generally treated. He had been associated with Sir Herbert Jackson for very many years, and he could quite understand that he expressed himself in a particularly friendly way when he came to addressing them on a resolution of this kind. It had been a great pleasure to him to come and talk about these things, and he hoped that some of the students would have found matter of interest in what he he had said.

LA VIE INDUSTRIELLE EN FRANCE.

LA FABRICATION DE L'AMMONIAQUE SYNTHÉTIQUE PAR LE PROCÉDÉ HABER, A LA POUDRERIE NATIONALE DE TOULOUSE.

Une partie de la Poudrerie de Toulouse, immense usine créée pendant la guerre et inexploitée depuis 1919, doit être bientôt affectée à la fabrication de l'ammoniaque synthétique, par le procédé Haber. Cette organisation, qui résulte d'une loi votée en avril dernier après de longs débats au Parlement, confie l'exploitation de l'usine à un "Office National de l'Azote."

Les besoins de la France en engrais azotés sont énormes; on les estime à près de 2 millions de tonnes d'azote, ou 70 kilogr. par hectare cultivé. Or, les terres n'en reçoivent guère que 45 kilogr. par hectare, et c'est une des principales raisons de la médiocre récolte française de blé (15 quintaux à l'hectare, en bonnes années), alors que la Belgique obtient jusqu'a 25 quintaux.

Les procédés de préparation des engrais azotés synthétiques sont nombreux; quatre seulement sont utilisés en France, dont trois par l'industrie privée: le système français Claude, le système italien Casale, et la cyanamide calcique, fabriquée dans cinq grandes usines hydro-électriques des Alpes et des Pyrénées. Le dernier est le procédé Haber, originairement propriété de la Badische Anilin und Sodafabrik, d' Oppau (Rhénanie), avec laquelle l'Etat français a conclu un contrat lui garantissant la bonne marche de sa fabrication.

Le projet primitif, de confier l'industrie privée l'exploitation de l'usine de Toulouse, n'a pas eu de succès, et la loi a prévu pour cela un établissement public placé sous l'autorité du Ministère des Finances, et doué de l'autonomie financière; il s'occupera de fabriquer et de vendre les engrais et produits azotés ou leurs accessoires. En fait, le Conseil d'Administration de cet Office de l'Azote sera presque entièrement composé de fonctionnaires supérieurs, et le contrôle parlementaire ne sera pratiquement assuré qu'en cas de déficit, à couvrir par des crédits fournis par l'impôt. Aussi a-t-on fait observer que cette concurrence faite par l'Etat français à l'industrie privée qui exploite d'autres procédés, est dangereuse pour celle-ci, que grèvent de nombreuses et lourdes taxes, en même temps qu'elle consacre une sorte de nouveau monopole d'Etat, au moment où les monopoles existants sont reconnus fonctionner avec un rendement très médiocre.

L'AVION BREGUET DU RAID PARIS-TOKYO.

On connaît le voyage remarquable exécuté par le Capitaine aviateur Pelletier d'Oisy et son mécanicien Besin, de Paris à Tokyo, du 24 Avril au 9 Juin. Le but principal de cette entreprise était de montrer la possibilité d'effectuer un voyage extrêmement long, à travers des climats divers, avec le même appareil monté et entretenu en état de marche par les mêmes aviateurs pendant tout le parcours.

L' expérience a été particulièrement probante, puisque les aviateurs ont été jusqu'à Shang-Haï avec le même appareil, et qu'ils auraient atteint vraisemblement Tokyo sur leur avion, sans leur accident d'atterrissage sur un terrain de polo. Ils ne purent repartir que quelques jours après, sur un avion vieux de 5 ans, avec lequel ils atteignirent enfin Tokyo. Ils avaient été de Paris à Shang-Haï en 92 heures de vol, couvrant ainsi 16,450 kilomètres (10,225 miles), soit à la vitesse de 178 km. 8 (111 miles) à l'heure. Le voyage s'était fait en 13 étapes, dont la plus longue avait été de

2,000 kilomètres (1,243 miles) faite en 11 heures. Le voyage complet jusqu'à Tokyo, représente un parcours de 20,220 kilomètres (12,564 miles).

Cette expédition montre, non seulement le courage et l'endurance des aviateurs, mais encore les bonnes qualités de l'avion qui a servi jusqu'a Shang-Haï. C'est un appareil du type de série Bréguet, biplan à deux places, de construction métallique, sauf le revêtement des ailes qui est en toile, muni d'un moteur Lorraine-Diétrich de 400 H.P. placé à l'avant. L'envergure de l'appareil est de 15 mètres (49 ft.) et sa longueur de 9 mètres (29½ ft.), la surface totale portante est de 50 mètres carrés (538 sq. ft.). Le moteur est à 12 cylindres en V, de 120 millimètres (4¾ in.) d'alésage et 170 millimètres (6 11/16 in.) de course, pesant en ordre de marche 410 kilogrammes (904 lbs.) et tournant à 1700 tours ; il entraîne l'hélice directement. Deux bielles voisines attaquent le même maneton, de sorte que l'arbre vilebrequin ne comporte que quatre paliers. L'allumage double est obtenu par deux magnétos à volet tournant, donnant 4 étincelles par tour.

Les soupapes sont en acier au chrome-tungstène. Les carburateurs sont à fonctionnement automatique ; ils comportent un correcteur altimétrique ; leurs corps sont réchauffés, pour éviter la formation de givre. Ils sont alimentés par deux pompes volumétriques à débit automatiquement règlable, à soufflet métallique évitant tout frottement.

La mise en route peut être réalisée à partir de la place du pilote, après injection préalable d'essence au moyen d'une pompe comprimant dans les cylindres un mélange dosé d'acétylène et d'air, à travers des clapets spéciaux. Ce mélange est enflammé par une magnéto de départ à main.

La puissance du moteur correspond à environ 18 H.P. par litre de cylindrée. La consommation moyenne est d'environ 240 grammes d'essence et 20 grammes d'huile par cheval-heure.

Le poids total de l'appareil, en ordre de marche, est de 2485 kgs. (5480 lbs.), avec les deux aviateurs et tout le matériel.

L'Essai des Aciers aux Etincelles.

Pour arriver à classer, sans perte de temps, les diverses catégories d'aciers, et aussi pour les distinguer d'autres métaux ayant un aspect analogue, un procédé dont le principe était déjà connu, vient d'être repris et mis au point par M. Pitois, Ingénieur en chef des Services techniques de l'Aéronautique.

Il est basé sur l'examen méthodique des étincelles que donne l'acier (ou la fonte) soumis à un meulage sur la meule d'émeri. La forme et la coloration de ces étincelles, produites par l'arrachement de particules microscopiques de métal que l'oxydation porte aussitôt à l'incandescence, caractérisent très bien la nuance du métal soumis à l'essai.

C'est le carbone de l'acier qui brûle ainsi, et par conséquent la combustion, donc l'incandescence, est d'autant plus intense que l'acier est plus carburé. Les éléments tels que le nickel, le tungstène, etc., agissent pour atténuer l'éclat des étincelles.

Toutefois, ces variétés d'étincelles sont difficilement perceptibles à l'oeil ; le procédé de M. Pitois est donc caractérisé par l'emploi d'un appareil photographique qui les enregistre et permet de les examiner, agrandies, avec tout le loisir voulu. Son dispositif comprend une boîte étanche où l'on peut remplacer l'air par de l'oxygène, et à l'intérieur de laquelle tourne une meule en émeri ; l'échantillon est présenté à cette meule sous pression constante. Un appareil photographique avec objectif à grande ouverture prend des vues sur plaques extra-sensibles, et les gerbes d'étincelles y apparaissent nettement différenciées.

Par exemple, les étincelles en fuseau, en fourche, en étoile simple, en étoile multibranche, en éclatements multiples, en houppe, en épis, en fleur, en bouquet de fleurs, caractérisent successivement les aciers extra-doux, doux, doux trempants, demi-doux, fortement demi-doux, demi-durs, fortement demi-durs et extra-durs.

On remarque la distinction de la nuance douce trempante par l'apparition de l'étoile, qui marque la limite des aciers propres à la cémentation et à certaines utilisations, notamment lorsqu'il s'agit de tôles, l'emploi comme chemise à eau dans les moteurs d'avion.

De même, aux étincelles, on voit tout de suite si une fonte grise, dont la caractéristique est une gerbe rouge sombre à rares éclatements en hallebardes, a une croûte blanche, dont la caractéristique est une gerbe brillante à éclatements en fleurs de lys, et l'on évite ainsi bien des détériorations d'outils.

Enfin, pour les aciers spéciaux, M. Pitois a publié des séries de planches photographiques fixant également les caractères principaux permettant de reconnaître chaque constituant, et notamment le silicium, le nickel, le chrome, le tungstène et le manganèse.

La plupart des aciers, qui dans l'air donnent des gerbes rouges, flambent dans l'oxygène sous l'action de la meule, mais il en est qui résistent, certains partiellement, d'autres totalement. La proportion et la fréquence des éclatements blancs renseignent immédiatement sur le degré d'inoxydabilité à haute température de l'acier essayé ; on a donc là un nouveau critère extrêmement précieux pour les aciers à soupapes.

L'emploi de la Chloropicrine pour étouffer les Cocons de vers à soie.

Les cocons de vers à soie doivent être étouffés pour tuer les chrysalides avant l'éclosion des papillons qui perceraient les coques et les rendraient inutilisables. En Europe, on opère l'étouffage par la chaleur, mais il faut éviter avec soin, aussi bien un excès de chaleur qui altère la soie, qu'un défaut de chauffage qui ne tue qu'une partie des chrysalides et donne lieu à des déchets importants.

Le froid artificiel est coûteux ; les gaz inertes ou toxiques tels que H, Az, CO^2, SO^2, AzH^3, etc., sont insuffisants, ou altèrent la soie. Mais on

vient de reconnaître, par des essais répétés, que la chloropicrine, gaz asphyxiant employé pendant la guerre, se prête très bien à l'étouffage, et on peut prévoir que son emploi sera précieux pour les filateurs français, dont l'industrie est si importante et met en jeu des capitaux de plus en plus grands, à mesure que la soie augmente de valeur.

AGRICULTURAL AND FOREST PRODUCTS OF CUBA.

According to the Report on the Economic Conditions in Cuba by the Acting British Consul-General at Havana, the *cattle-breeding* industry of Cuba is probably the third in order of importance amongst Cuban industries, coming after the sugar and tobacco industries. The capital invested in cattle breeding is some $350,000,000.

Of the superficial area of some [illegible]01 million acres, roughly one-third is devoted to cattle-breeding, although in a somewhat primitive way. There is no particular cultivation of pastures except in certain places, chiefly in the provinces of Camaguey, Santa Clara and Oriente (Bayamo and Manzanillo).

There are to-day some 4,500,000 head of cattle in the Island. They are of very mixed breed; Durham and Devonshire blood is visible in Camaguey and Oriente and Hereford in Santa Clara. After the War of Independence, when the industry was practically destroyed, a great number of cattle for stud purposes were imported from Jamaica. In the province of Havana where dairy farming flourishes, the breeders favour Holstein and Jersey blood.

A large number of animals are still imported for stud purposes, almost all coming from the Southern States of the United States of America, as animals from these parts acclimatise themselves more readily.

The health of cattle is good, though the feeding presents a problem, but breeders have planted large areas of guinea grass on the high lands and Parana grass on the low-lying swampy lands with good results.

The general state of the industry is good and the prospects excellent.

Some 8,[illegible]00 acres of land are now under *henequen* cultivation, but there remains at least 1,000,000 acres suitable for this purpose. The largest company cultivating henequen and elaborating the fibre owns some 200 caballerias under cultivation, with headquarters in Matanzas.

The annual production of fibre is estimated at eight million pounds weight, and the output of rope, cordage and string is in bulk about equal to the total production of fibre; in addition to a considerable local consumption it is largely exported. This industry is capable of expansion, but it means the tying-up of capital for about four years before results can be obtained.

Grape fruit in Cuba, and more especially in the Isles of Pines, has been a fairly good proposition, but the industry has gone back in the last ten years, and to-day there are only some 5,000 acres under cultivation in Cuba proper.

The approximate yearly yield in Cuba is probably about 50,000 boxes, of which some 10,000 are exported to the United States of America. The London market takes about 25,000 crates per annum, but this could no doubt be increased. While the industry in Cuba proper is going back there are prospects of further developments in the Isle of Pines due to the more favourable climatic conditions.

In the Isle of Pines there are about 2,500 acres under cultivation, and some two and half million dollars are invested—entirely American and Canadian capital. New York receives some 50 per cent. of the output, Chicago 40 per cent., and other places in Canada and Europe the balance.

In 1922 a total of 217,731 crates of grape fruit was shipped from the Isle.

Timber.—About one-sixth of the area of Cuba can be termed forest land, and the best of this is situated in the provinces of Camaguey and Oriente.

The principal and most valuable Cuban woods are, in their order of importance: cedar, mahogany, and "majagua" (of the linden family). There are, however, many others, uses of which are restricted either by quality or quantity.

The approximate annual consumption of timber is about 25,000,000 feet, valued at $2,300,000. Exports are about 4,000,000 feet annually, 75 per cent. of which is mahogany, 20 per cent. cedar and the rest "majagua" and other woods. The annual value of timber exported is about $360,000. About 80 per cent. of the export is to the United States of America and 20 per cent. to Europe.

The cultivation of *coffee*, formerly a valuable Cuban industry, with headquarters in Oriente province, has been steadily decreasing for a number of years, and finds itself at present in a very grave condition, so grave indeed that about two-thirds of the producers are inclined to abandon the cultivation. The reasons underlying this state of affairs are, according to the producers, the entire lack of Government support, the high rate of interest charged on loans, viz., from 1 per cent. to 5 per cent. monthly, and the shyness of capital. Two measures which have been recommended are: (1) An educational campaign directed towards better methods of cultivation; (2) a Government loan to the Association of Coffee Producers of not less than $200,000 from which that Association can make loans to the producers of three years' duration at a rate of interest not exceeding 6 per cent. per annum.

MEETING OF THE SOCIETY.

◆

DOMINIONS AND COLONIES SECTION.

THURSDAY, JULY 24, at 4.30 o'clock:—M. FRANCK, late Colonial Minister of the Belgian Government, "Recent Developments in the Belgian Congo."

Journal of the Royal Society of Arts.

No. 3,739. VOL. LXXII.

FRIDAY, JULY 18, 1924.

16 AUG 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICES.

NEXT WEEK.

THURSDAY, JULY 24th, at 4.30 o'clock (Dominions and Colonies Section.) M. FRANCK, late Colonial Minister of the Belgian Government, "Recent Developments in the Belgian Congo." The Hon. W. ORMSBY-GORE, M.P., will preside.

EXAMINATIONS.

The number of papers worked at the Society's Examinations this year is 67,280. This constitutes a record, and is an increase of 2,762 over the total for 1923, when the number was 64,518. For the first examination, held in April, the papers worked numbered 25,778, as against 21,288 in the corresponding examination last year. For the May-June series the papers worked numbered 41,502. For the second examination last year, the number was 43,230. In the Advanced Stage, the total for both examinations is 8,419 compared with 8,688 last year. In the Intermediate Stage the totals are 23,762 in 1924, and 23,132 in 1923. The figures for the Elementary Stage are 36,099 this year, and 32,698 last year.

The principal subjects taken and the number of papers worked in each were:—Book-keeping, 20,410; Shorthand, 13,523; Arithmetic, 7,465; Typewriting, 6,476; English, 5,691; French, 4,808; Theory and Practice of Commerce, 1,040; Commercial and Company Law, 740; Accounting, 621.

The examinations were held in most of the principal cities and towns of Great Britain and Ireland, and in nearly all cases were conducted and supervised by the Local Education Authorities.

There were 363 Centres for the April Examinations, and they were held at 345 Centres in May-June. The County of London, where the Examinations are under the control and supervision of the London County Council Education Committee, is only counted as one Centre, though it includes entries from nearly 200 Evening Institutes, Polytechnics, Proprietary Schools, etc.

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

WEDNESDAY, MAY 14th, 1924.

MR. ERNEST POLAND, Vice-President of the London Fur Trade Association, in the chair.

THE CHAIRMAN, in introducing the lecturer, said Mr. Ingrams had for many years been associated with the celebrated Hudson Bay Company, and no one could have been selected who was better able to deal with the subject.

The paper read was:—

FURS AND THE FUR TRADE.

By F. C. INGRAMS,

President of the London Fur Trade Association.

We should not be wrong in saying that the fur trade is perhaps the oldest trade in the world, as it probably dates from the Bronze Age, when barter at least took place in articles which exceeded the personal needs of the producers. In any case, the necessity to our remote ancestors of wearing skins of animals for their first primitive garments originated at a still more distant period. The first traces of the use of skins as clothing are to be found in the Palæolithic or Early Stone Age. From deposits of this age, flint implements which were used as scrapers for preparing skins have been found. Here is one found in Essex a few months since, and here is one from the Arctic regions which I brought home two years ago. In the Neolithic or Later Stone Age, we find these implements much improved, besides needles of bone for sewing the skins together into clothing, the thread for this purpose being made from sinews.

Amongst other animals of which remains have been found belonging to this latter period are those of bear, badger, wolves, pine stone martens, foxes, otters, beavers, polecats and wildcats. In the Bronze Age skins were extensively used for garments, though traces of woollen and linen fabrics of that period have also been found.

It is uncertain, however, whether the finer sorts of furs were utilised until the barbarous Northern tribes became more civilised and a demand arose for objects of adornment.

Almost the first notices of importance of a traffic in furs are those referring to the Scythians, the inhabitants of the modern Russia, whose commerce is stated by Herodotus in the 5th century B.C. to have consisted principally of peltry, a commodity in which they had long traded.

The Greeks and Romans do not appear at first to have worn furs, even as an article of luxury, though Cæsar, and later Sallust and Tacitus, relate that the German tribes were clad in skins, which were deemed a badge of barbarism ; and it was not until the 3rd century of our era that a taste for this mode of adornment began to be acquired by the Romans from their contact with the Northern people. The invasion of Italy by Gothic nations at the end of the 5th century, and the rule at Rome of a Gothic king a short time later, had the effect of further introducing amongst the Romans the custom of wearing furs, thus giving rise to the first fur trade from the North with South European civilisation.

The Black Sea trade, though of importance in earlier times, received considerable impetus after the building and dedication of Constantinople by the Emperor Constantine in 330 A.D., and amongst the articles of commerce, furs found their way to this city, which was shortly to rise to great prosperity.

A fur trade of importance was carried on from Russia by Norse and Danish traders, by way of the Baltic and North Seas in the 8th and 9th centuries. It is at the latter period that we hear of expensive furs being worn at the Court of Charlemagne and of ermine being known in England. In the 9th century the Muscovites (or Russians) were engaged in an important traffic in peltry from the North to Constantinople, then the great emporium for European commerce, the trade growing in volume in the following century as the demands of Western Europe increased, whilst the Northern commerce with Germany developed in like manner.

After the beginning of the Crusades in 1096, intercourse between East and West increased and exercised an important influence on commerce generally, especially in articles of luxury, and the appreciation of furs for adornment was now greatly augmented. The upheaval in the political world considerably affected the fur trade of the Norsemen and Danes with Russia, and as a result, the Italians, both Venetians and Genoese, whose commerce had been slowly gaining strength during the two preceding centuries, secured a strong position in the trade from the East. Constantinople rapidly declined in importance as a commercial centre, goods from the Black Sea ports only passing through that city on their way to the marts of Genoa and Venice. By the 12th century furs had begun to be used to a still greater extent, though the finer and more valuable sorts were chiefly confined to royalty and persons of high rank, and restrictions were made in their use, at least amongst the clergy. Furriers are now heard of in increasing numbers, and associations or guilds were formed for the proper regulation of the trade. The Zunft of Kurschner (Guild of Furriers) at Quedlinburg in 1134 is probably the oldest, Rouen (1160) being second and Florence (1197) third.

The fur trade in Europe experienced a further expansion in the 13th century, records and chronicles showing the widespread extent to which the use of furs had then attained. From a very early date German merchants established themselves in London, and later others from the Northern towns of Germany were granted privileges of trading at Bergen (in Norway) at Novgorod (in Russia) and many towns in Flanders, Germany and Russia. These traders were the predecessors of the great Hanseatic League, which from about the year 1280 began to build up its immense commerce of the North. This trade consisted largely of furs, which were exported from Novgorod and other places in the interior of Russia, through the Baltic ports to towns in Germany, England and Flanders, the chief emporia being at Novgorod, Lubeck, Cologne, Brunswick, Dantzic, Bergen, Bruges and London.

During the two succeeding centuries (14th and 15th) the vogue became more and more accentuated, all classes wearing furs according to their means, while prices advanced in sympathy with the demand. So great was the indulgence in the use of these and other objects of luxury during this period, that a succession of sumptuary laws were passed in nearly every country of Europe with the object of checking extravagance, but in most cases with little or no effect. The trade was now at its zenith and supplies from Russia, Scandinavia, Germany, etc., reached a very large total. Guilds of furriers were established in nearly every town of importance in Germany, France, Flanders, England and Italy: the Berlin Guild was founded in 1280, the Skinners' Company of London received its charter in 1327, and that of Paris, about 1395, though in each of these cities the industry had been established long prior to these dates. Fairs formed an important medium for the distribution of peltry, and were attended by merchants and furriers from all parts; the most notable fairs in the Middle Ages were those at various towns in Champagne and Brie in France, where both Germans and Italians brought their furs for sale at Paris and Bruges, St. Botolph (Boston), Winchester, St. Ives, Stamford and St. Edmund in England. Bruges and Antwerp were at this time the principal entrepôts in the North of Europe for foreign produce, but by the beginning of the 16th century, the trade of Bruges had declined in favour of Antwerp, which in Elizabeth's time was known as the principal market for furs from all parts.

The principal furs of the better class in use in the Middle Ages were European marten, Russian sable, ermine, lettice, otter, budge, beaver and squirrel, of which latter there was an enormous consumption in its various forms and under different names (some of which were Bis, Gris, Vair, Gros Vair, Miniver, Calabre, Cristigrey, Polayne, Ruskyn, Popel and Strandling): of the commoner class, cat, coney, lamb, fitch and fox: foynes, Genet, Lucerne and mink do not make their appearance until about the 16th century.

The following list of explanations of some of the names of furs in the Middle Ages and early modern times may be of interest:—

Obsolete Names of Furs.

Lettice. The white fur of the snow weasel of North Russia: still used in small quantities as a cheaper sort of ermine; the tail is smaller than that of the ermine and has no black tip.

Budge. Black, and sometimes white, lambskin: originally from Bougie in North Africa, but afterwards used to designate any of the more valuable and curly sorts of foreign lambs.

Pampilion. Lambskin from Pampeluna in Spain, probably identical with "Budge of Navarre" in the Customs Accounts.

Bis. The fur of the back of the Siberian squirrel in its winter coat and in its best or dark grey colouring.

Gris. The same, but of ordinary grey colour: also used as a general term for the grey back of the squirrel.

Popel. Squirrel fur in spring, but not of a pure grey colour.

Ruskin. The same in summer time and of quite a reddish hue.

Strandling. Squirrel fur in its autumn coat, tinged with red.

Polayne. Squirrel fur from Poland, the grey of the back a very dark shade.

Calabre. Squirrel skins from Calabria of a very dark grey or black, but poor in quality: the name was used very much later by the British Customs as a comprehensive term for Siberian squirrel.

Vair. A general name for the whole skin of the Siberian squirrel, both grey back and white belly together and generally when manufactured into linings.

Gros-Vair. Really the same, but used to distinguish it from Miniver (Menu-vair).

Miniver (French, menuvair). The under part of the squirrel, with part of the grey sides remaining—the same as the present squirrel lock-lining. The name has for some time lost its former signification and is now represented by ermine, with spots of black fur.

Pured miniver or *puree* was the term used when the grey sides had been removed, leaving only the white belly.

Foynes. The fur now known as stone marten.

Lucerne. Lynx fur, only the underneath part of which was generally used, being whitish with irregular dark spots.

John Cabot, a native of Venice, at the expense of certain Bristol merchants discovered America in 1497. Frobisher, Button, Fox and Hudson had in their attempts to find a north-west passage to India and so circumvent the monopoly of trading in the Pacific granted to the East India

Company, had each succeeded in discovering new lands which bear their names.

It was these discoveries that gave title to the Government by whose subjects or by whose authority they were made, which title might be consummated by possession.

In 1553 the organisation of the Russia Company took place under the title of "The Mysterie and Companie of the Merchants' Adventurers" for the discoverie of regions, dominions, islands and places unknown. The Right Worshipful Master Sebastian Cabot was appointed Governor of the Company, which was the first of the great English joint-stock companies for foreign trade.

King Edward VI. interested himself in this adventure and entrusted Richard Chancellor, who was appointed to the command of the expedition, comprising three ships, with letters to the Kings, Princes and other Potentates inhabiting the north east parts of the world.

Chancellor discovered the Bay of St. Nicholas and delivered the letters from the English King to the Emperor of Russia, Ivan Vasilowich.

These letters were acknowledged from Moscow in the second moneth of February in the yeare 7060 (old calendar) and sent to King Edward in 1554. As a result of this voyage and discoverie of Russia by Chanceler, King Philipe and Queene Marie granted the Russia Company a Charter of trade and a fellowship in Communaltie with a Governor, Consuls and Assistants. Thus our trade with Russia was commenced, but the Company's methods of finance were faulty and there were several reconstructions —its concessions were annulled in 1646, but the fellowship continues to the present day.

The trade opened up between England and Russia had an injurious effect on the Hanseatic League, whose methods were offensive to the Emperor of Russia. Their privileges in England had been greatly modified, but when the Emperor Rudolph ordered the factories of the English Merchant Adventurers in Germany to be closed, Queen Elizabeth in 1598 directed the Lord Mayor of London to close the house occupied by the Merchants of the Steelyard. It may be of interest to note that the site of the steelyard is where Cannon Street Station now stands.

There is little doubt that Siberia's vast wealth in sable and other furs had for a long period excited the cupidity of the Russians, but the conquest of that country was not commenced till the reign of Ivan the Terrible in 1580. From that time various expeditions were sent from Russia, during most of which large quantities of valuable furs were obtained, and from the period when the whole country came into the possession of the Russians, considerable trade developed and though affected by the Great War, exists to the present day.

The discovery of the mainland of North America by John Cabot in 1497 led to the gradual opening up of an entirely new source of supply for the fur trade, and, as the years went on, to a complete revolution in this important branch of commerce. Long before the earliest fur trading companies were formed, Newfoundland fishermen bartered peltry with the natives. Gomez in 1524, from the mouth of the St. Lawrence, and J. Cartier in 1534, from Newfoundland, both brought back furs with them to Europe. From this time onwards, an irregular though increasing traffic was conducted, chiefly by French traders, and in the latter years of the same century assumed dimensions of importance, though still only a coasting trade. In 1599, the first monopoly was granted to Chauvin, who for three years enjoyed large profits, and from 1602, other companies of increasing power succeeded to these rights, none of them lasting any length of time on account of the continued complaints of those excluded from the trade and of the want of any proper attempts at colonisation.

In the meantime, foreign vessels began to take a share in the commerce; the Dutch appeared in the St. Lawrence and robbed the French of their furs. The latter, however, continued to carry on a lucrative business in spite of opposition. The English Virginia Company (created in 1606-9) also began to press upon the French trade from the south, whilst from New Amsterdam (founded in 1614) large quantities of beaver were shipped to Holland. The French in Canada still went on trading under the domination of Company after Company, under De Monts, Champlain, Montmorency, Caen and others. In 1621, the Dutch West India Company was formed and, devoting itself to the fur trade, sent home numbers of skins of all sorts, chiefly of beaver, which was the principal fur in the early days of this commerce. A Scottish and English company was organised in

1628-9 for fur trading in the St. Lawrence, at the time of the war between England and France, leading to seizure of French vessels, raids on settlements and finally, after the fall of Quebec, to the capture of the entire St. Lawrence trade. A few years later, on the restoration of peace, restitution had to be made to the French, though in the meantime their rivals had enjoyed the whole profits from this region. "La Compagnie des Cent Assoces" was granted a charter by Richelieu in 1627, but their trade in furs was in a short time entirely appropriated by the Dutch and other foreigners. La Compagnie exercised control over New France until 1663, when it was ceded to the Crown, and "La Compagnie des Indes Occidentales" was granted a Charter for the Prosecution of the fur trade in 1664, but the country was finally taken under the control of the French King, resulting in rapid progress in colonisation and trade.

In 1664 King Charles granted the territory of New Amsterdam, now comprised in the States of New York, New Jersey and Delaware to his brother, the Duke of York, who wrested it from the Dutch, and the fur trade fell into English hands.

Perhaps, however, the most important factor for the British Empire arising out of the fur trade was the granting of the charter by King Charles II. on the 2nd May, 1670, to Prince Rupert and his associates for incorporating the Hudson's Bay Co. for the purpose of, among other things, the discovery of a New Passage into the South Sea and for the finding of some trade in furs.

The events that led up to the granting of the charter deserve to be more fully dealt with than is possible in a paper of this kind, but as these events secured to the British Empire that vast and loyal Dominion of Canada, and the granary of the Empire, I am impelled to mention it, however briefly.

In 1658, two Frenchmen named Radisson and Grosselliers, who were in the employ of La Compagnie des Cent Assoces became dissatisfied with the limitations of their prospects and commenced trading for their own account without the permission of the Governor. On their return to Quebec Grosselliers was imprisoned and the partners were fined £10,000. On his release, they crossed to France to seek restitution and to obtain support for a voyage to Hudson Bay. Having failed in both these objects, they eventually, through the influence of Sir George Cartwright, one of the Royal Ambassadors in America, obtained an interview with King Charles in 1666 and the support of Prince Rupert.

In 1667 the First Stock Book of the Hudson's Bay Company records that substantial sums of money had been provided for the adventure by such men as Prince Rupert, the Duke of Albemarle, the Earl of Arlington, Earl Craven and others, and, in 1668, two vessels, the "Eaglet" and "Nonsuch" sailed for Hudson Bay. The "Eaglet" failed in her attempt, but the "Nonsuch" sailed through Hudson Bay to James's Bay and established a post at the mouth of Rupert's River, and in 1669 returned to England with a cargo of furs. On the success of this voyage, those who had supported the enterprise applied for a Royal Charter, which, as already stated, was granted on the 2nd May, 1670, to the Governor and Company of Adventurers of England, trading with Hudson Bay.

The first few cargoes of furs were sold privately, but on the 24th January, 1671, the first public sale of furs was held by the Company in London at Garraway's Coffee House. The minutes of the meeting referring to the sale ordered :—" That the substance "of the preamble to the Publick Sale "which is to be to-morrow be that the "quantity of Beaver to be sold is divided "into 27 Lots of about 100 lbs. to a Lot, "the price 7s. per lb. to advance two-pence, "to pay at a month, and not to take away "the goods before payment be made "and that but 3,000 lbs. or thereabouts of "Beaver more is to be sold by the Company "and that not before May next."

From that date down to 1914-15, when there was a slight interruption owing to the Great War, the Hudson's Bay Company have sold their collections of furs in London by public auction and have been in a large measure instrumental in maintaining London as the centre of this important entrepôt trade, the quality and handling of the offerings being such as to command the attention of the fur trade of the world.

The Company was not considered enterprising in exploring the interior, but the chief reason for this apparent neglect was that during the long traverse from the hunting grounds to the trading posts in the spring, when the fur is of inferior quality and the animals rear their young, the Indians were compelled to suspend hunting operations.

During the early years of the Hudson's Bay Co.'s venture, new French trading companies followed each other in endeavouring to secure to themselves the fur trade of Canada and Louisiana, viz., the "Compagnie de l'Arcadie" (or "du Castor") founded in 1683, "de la Louisiane" (or "d'Occident") 1684, "du Mississippi" (1684), the new "Compagnie du Canada" (or "de la Nouvelle France") 1706, (which surrendered its headquarters at Quebec to the Hudson's Bay Company at the Treaty of Utrecht in 1713) and the Cie. des Indes. In 1717, the "Compagnie d'Occident" was joined with the "Compagnie des Indes" and the latter in turn absorbed in 1719 various other French colonial companies, but the enormous undertaking collapsed in 1721, though the company was reconstructed and continued its fur trade. Beaver was the principal article of export of most of these companies, but other furs formed a substantial part. The goods were shipped to French ports, chiefly to La Rochelle, and in 1743 the quantities were still very considerable. The French fur trade in Canada after the cession of the country to England, in 1763, gradually became merged in the North-West Company from Montreal. In the course of its early struggles with the French in Canada and later with the North-West Company of Montreal, the Hudson's Bay Company's trade in furs experienced very uneven fortunes, but after the amalgamation with the latter company, in 1821, a peaceful and prosperous trade was developed and large shipments of furs made to London.

In March, 1778, about 300 years after Columbus discovered America in 1492, Capt. Cook, in command of a Royal Exploring Expedition with the "Resolution" and the "Discovery" discovered Oregon, where the natives were dressed in long robes of sea otter skins. These were traded for pieces of metal, but after exploring in the North, Capt. Cook proceeded to the Asiatic side, where, being no longer in need of warm clothing, the sailors traded their furs with Russian fur traders in Kamschatka.

These beautiful pelts which are now so rare used in the early days to realise less than the land otter, which is about half the size and has about one-third the depth of fur.

Chief Factor—afterwards Sir James—Douglas commenced the construction of Fort Victoria, Vancouver Island, in 1843, a few years after the English navigator, George Vancouver, had circumnavigated the island. For many years the company, by means of the famous steamer "Beaver," traded with the natives along the British Columbian Coast. The "Beaver" was built for the Hudson's Bay Company, and was the first steamer to cross from the Atlantic to the Pacific.

On the settlement of the International boundary Oregon and Washington were ceded to America and the 49 parallel of latitude was adopted for the boundary line, but access to the sea was retained by way of the Columbia River.

The fur trade of the Missouri Valley, though originating under the French early in the 18th century, never developed to any great extent until after Louisiana came into the hands of the United States, and it was largely the result of the expeditions by Lewis and Clark via the Missouri and Rocky Mountains across the continent to the Pacific, in 1804-6, and that of Pike at about the same period from St. Louis up to the Mississippi, which really opened up this fresh field of operations for the fur trade. In 1808, the Missouri Fur Company was founded and rose to some importance under Manuel Lisa. It was reorganised in 1812, but became extinct about 1830. In the same year that the last-mentioned company came into existence, the well-known American Fur Company of New York was organised by John Jacob Astor, a native of Germany. Practically the whole control was in his own hands and it was due to his enormous energy and great business acumen that its affairs rose to such gigantic proportions, Astor eventually crushing all opposition or buying up his competitors. The company made many enemies, whilst its methods were at times open to much criticism. One of its chief rivals, the Rocky Mountain Fur Company, was initiated by Ashley in 1822 and succeeded in establishing a considerable trade in the West, but the undertaking was dissolved in 1834, through inability to stand against its formidable opponent. The Pacific Fur Company, which commenced trade in 1810, was actually only the American Fur Company under a different name for the purpose of conducting the Western trade. The following year saw the foundation of Astoria at the mouth of Columbia River on the Pacific under the auspices of Astor's Company, but the post never succeeded and was sold to the North-

West Company of Canada three years later, during the second American War with Great Britain, the name Fort Astoria being changed to Fort George. The Columbia Company was another enterprise of importance, formed in opposition to the American Fur Company, but after five years' trade was united to the latter. Still another combination of traders, the Mackinow Company, established by the British for operation in the United States, was also bought up by Astor and others in 1811 and re-named the South West Company, in contradistinction to the North West Company. The South West Company and the Pacific Fur Company were practically ruined by the war of 1812-14, and two years later, after the exclusion of foreign traders from the fur trade of the United States, the American Fur Company took over the interests of both these concerns. A few years afterwards, the latter was reconstructed, one portion operating from New York and the other from St. Louis, which had been since 1807 the real centre of the Trans-Mississippi fur trade. Astor, after having amassed an immense fortune, retired in 1834 from the company in which he had taken a leading part for so many years. He foresaw the inevitable fall in the price of beaver, caused by the substitution of silk for fur in the manufacture of hats, and it was only a short time afterwards that the great collapse in price took place. On Astor's retirement, the Northern department of the American Fur Company was sold to a company with Ramsay Crooks as predominant partner and the Western (St. Louis) Department to Pratte, Chauteau and Cie. of that city, though the name of the American Fur Company was still used. In the same year, the Rocky Mountain Fur Company was absorbed in the latter undertaking.

The Russian trade in furs from Alaska had its origin from the time when, following on the discoveries of Vitus Behring in 1728, a Dane who entered the Russian Navy was appointed by the Empress Catherine to command an Expedition of discovery in North East Asia; further exploring expeditions of his returned with considerable numbers of fur seal, sea otter and fox skins from the islands of Behring Sea. From 1748 until nearly the beginning of the 19th century, vessels were sent out from time to time, chiefly from Kamschatka for trade with the Aleutian and other islands, but it was towards the end of the 18th century before any great development of the fur trade took place in these regions. About this time, the Russian merchant, Skelikoff, with whom Baranoff was shortly afterwards associated, made considerable progress in opening up trade and the former's company met with a good measure of success. In the year 1799 the Russian-American Company, which, with headquarters at St. Petersburg, arose from the amalgamation of Skelikoff's and other companies, received its charter from the Emperor Paul, obtaining a monopoly of trade and exclusive right of territory in the new Russian possessions in Alaska and the islands of the North Pacific in addition to Kamschatka. The Emperor himself, besides nobles and Government officials, became shareholders of the company, so great was the interest shown in the undertaking. Baranoff was for many years the leader in the subsequent operations. In 1839 the Hudson's Bay Company leased South Eastern Alaska from the Russian America Company for a term of years. The lease was granted because the company had secured the most strategic fur trade positions and the Russians were anxious to checkmate the Hudson's Bay Company. To this end they built a line of blockhouses, one of which still remains at St. Michael.

Permanent settlements and trading ports or forts were established both on the Aleutian and Pribilof Islands and on the mainlands, resulting in a valuable trade being built up, principally in the furs of Alaska and the Aleutian Islands. These consisted of sea and land otters, beavers, foxes (red, cross, silver, blue and white) martens, minks, black and brown bears, wolverines, lynxes: and, in addition, fur seals from the Pribiloff and Commander Islands. Further supplies of furs were obtained by the company from Kamschatka and all were shipped to Russia or to China, via Siberian ports and Viatka.

Since the discovery of the Commander Islands in 1741 and of the Pribilof Islands in 1786, the skins of fur seals had been secured by various Russian trading companies, without any discrimination as to economy or method in taking. Large quantities taken in the Pribilof Islands had accumulated in 1803, and as the Russians were unable to dispose of such numbers before the skins began to rot, it is said that of 800,000, 700,000 were thrown into the sea. The use of salt for preserving the pelts was not practised until 1868, although this method had been employed long before in the fur seal fisheries of the Southern Seas. The skins were despatched mostly via Okhotsk to Viatka on the Chinese border, where they were bartered for tea and other Chinese produce. In 1805, killing was stopped for five years with beneficial results, and from 1820 to 1867, the average quantity of skins shipped annually from the Pribilof Islands to England, the United States and China was 42,000. The transfer of Alaska and the Seal Islands by Russia to the United States in 1867 ended the monopoly of the Russian-American Company. In 1870, a twenty years' lease of the Pribilof Islands was granted to the Alaska Commercial Company of San Francisco, who were allowed to take 100,000 skins annually, this company under a different name in the following year securing from Russia the right to take seals from the Commander Islands for a similar period, up to the number of 40,000 to 50,000 skins annually. In 1890, the new North American Commercial Company of San Francisco, succeeded to the next twenty years' lease of the Pribilof Islands, whilst the Russian Sealskin Company of St. Petersburg in 1891 obtained the fresh ten years' contract for the Commander Islands, which was renewed for a like period in 1901. On the expiry of the Pribilof Islands lease, in 1910, the United States Government themselves took over the control of the seal herd. Owing to the destruction of female seals at sea on their way to and from the breeding grounds on the islands by schooners from Victoria, San Francisco, etc., beginning in about 1870 and rapidly increasing down to 1893, the number killed on the Islands had to be considerably reduced in order to prevent extermination. Seizures of British Canadian sealers in the Behring Sea by the United States led eventually to the Paris Fur Seal Arbitration of 1893, the award of which resulted in certain restrictions being agreed to by Great Britain and the United States. But the latter, on the other hand, were unable to make good their claim to the Behring Sea as a *mare clausam* or to their property in the seal herd. The protection thus afforded to seal life was, however, insufficient to prevent further decimation, the Japanese, who were not included in the Paris agreement, now appearing in the Behring Sea, unhampered by the restrictions imposed on the Canadian and United States sealers. Consequently, an International Conference between Great Britain, the United States, Russia and Japan was held at Washington in 1911, and a treaty was signed stopping all further killing at sea for a period of fifteen years, compensation being given to those nations engaged in sea (or pelagic) sealing. On the Pribilof Islands about 20,000 skins are at present taken annually, and on the Commander Islands a negligible quantity, but the herd is steadily increasing in numbers, owing to the cessation of the killing of female seals.

It is doubtful when sealing in the southern hemisphere actually commenced, but at the close of the 18th and beginning of the 19th centuries hundreds of thousands of fur seal skins were taken from the South Shetland, South Orkney, South Georgia, Sandwich group, Falkland and other islands in the South Atlantic or Antarctic Oceans, from Juan Fernandez and Mas-a-fuera Islands in the South Pacific and from the Crozets and Kerguelen Island, besides others from islands to the South of Australia and New Zealand. From 1821 to 1823 320,000 skins were obtained in two years from the South Shetlands alone and, it is said, over 3,000,000 from Mas-a-fuera within seven years. These operations almost resulted in extermination, and few seals are now obtained from these regions, though the breeding grounds on the islands near the Cape of Good Hope and Cape Horn and on Lobos Island still furnish a moderate number, protection having been afforded by the Governments concerned. The greater portion of the skins obtained in the early part of last century from the herds of the Southern Seas were shipped to Canton for use in China, thus enabling English and American traders to compete with the Russians for this market.

The Chinese are said to have invented, as early as 1799, or before, a process of plucking the coarse hairs from fur seal skins and of dyeing the soft under-fur in various colours. Whether this be true or not, "unhaired" seal skins were not used in the English fur trade until about 1815, and then only in small quantities. A person of the name of Thomas Chapman had claimed in 1816 to have discovered in 1796 a means of producing the same result, though for some few years the under-fur was principally used only after being removed from the skin for felting and making into soft articles of wear. Dyeing the under-fur on the skin was known in London in the year 1816, though no extensive use was made of fur seal skins so treated until later.

Although fur bearing animals are naturally associated with the colder regions of the world, and the choicest kinds are usually found in the cold regions, furs now reach us from many sources unknown to the old traders, and although the principal supplies still come from North America (*i.e.*, Canada and the United States), viz., marten, mink, musquash, skunk, beaver, lynx, otter, foxes (silver, cross, red, white, blue grey), raccoon, bear (black, brown and grizzly), fisher, wolves, wolverine and American opossum, and from Siberia and Russia, viz. :—Squirrel, sable, ermine, foxes, kolinsky, foals, marmot and white hares, we have in addition, China and Japan in more recent years exporting quantities of the cheaper kinds, namely :—"Thibet," lambs, thick furred goats, kids, red foxes, mink, etc. Since 1870 Australia began to send opossum, wallaby, red foxes and rabbits, the quantities shipped now amounting to a large annual total. South America yields nutria, foxes, chinchillas and otters, whilst from Africa come leopards, otters and monkeys. From Bokhara (Asia) are imported in great numbers skins of the valuable so-called Persian lambs. Europe (as formerly) furnishes Baum (pine) and stone martens, fitch (polecat), otters, genet, ordinary lambs and large quantities of red foxes.

Siberian furs, until the Great War, were chiefly brought into the market at certain fairs, the most notable of which were held at Irbit, Yakutsk and Obdorsk in Siberia, and Nijni Novgorod in Russia : these furs are now exported direct to London or New York. At Leipzig, in Germany, there is an annual fair at Easter, at which offerings of furs are made, including purchases made at the London sales, but its importance has greatly decreased, owing to the war.

None of the older fur companies of North America now exist, with the exception of the Hudson's Bay Company, the trade generally being in the hands of private firms or companies. A very large part of American furs come to the London auctions of the Hudson's Bay Company, C. M. Lampson and Co., F. Huth and Co., and other firms. These sales are held periodically and attended by buyers or their agents from the principal centres of the fur trade.

Australian, Chinese, Japanese, South American and African furs are dealt with in a similar manner by Edward Barber and Son, Eastwood and Holt and Henry Kiver and Co.

Thus the world demand which has increased with the population has been met by bringing furs from practically all quarters of the globe. The geographical position of London has proved it to be the most convenient distributive point for the world's supplies of raw furs ; added to this, shippers and buyers can rely on the skins being assorted and catalogued in accordance with the Englishman's accepted standard of integrity.

In 1752-60 the average annual collection of mink was 36 skins. The collection gradually increased till 1881-90, when 59,500 skins was the average annual collection. During their last season, the Hudson's Bay Company collected and sold 55,900 skins.

Musquash. For the period 1752-60 the average annual collection of musquash was 93 skins. The collection increased until 1901-10, when the average collection was 837,300 skins.

For the past year the quantity brought to market was 985,700 skins.

The advance of civilisation and the increase in agriculture is leading to the draining of swamps, and will, doubtless, affect the quantities collected of this pelt in the future.

Lynx. In the period 1752-60 the collection in average was 2,700 skins, and the highest quantities were reached in 1881-90, when 32,400 skins was the average annual collection.

Since then the periodic increase and decrease in quantities failed to repeat itself.

Marten in 1752-60 furnished an average of 14,700 pelts, and increased to 118,000 skins in average for the decade 1851-60. For the season just closed only 25,000 skins were offered by the Hudson's Bay Company. Of course, many skins now find their way to other collectors, but there is no doubt that the felling of timber, forest fires, and lack of re-afforestation are responsible for a great diminution in the numbers of this beautiful pelt.

The Buffalo, except for private herds, is now practically extinct. It would have been impossible, however, to develop agriculture and to have countless herds of buffalo roaming the plains.

Much has been done by conservation to protect the beaver, but it stands a grave risk of becoming unpopular with the farmer owing to its wonderful method of damming streams and flooding considerable tracts of country.

The wolf is friend of neither man nor beast, and the Government grant a bounty of $10 per head for every pelt turned in. The fur value, of course, is greater than this, but the lack of sympathy for the wolf causes it to be killed in and out of season.

The breeding and rearing of fur bearers has made great strides during recent years. According to the Dominion Bureau of Statistics for 1922, there were 977 fox farms in Canada with a total of 24,163 foxes. Although the fox has proved the most suited to domestication, other varieties of fur-bearing animals are being raised in captivity—mink, raccoon, skunk, marten, fisher, beaver, musquash. In the States of America there are 350 fox breeders and in the Alaska region some 200. Our American cousins signalled their entry into this business by placing a 60% ad valorem duty on silver fox skins imported into the country, and so emphasised the slogan "America for the Americans."

In the case of some of the smaller animals, there is not the same danger of extermination since these seem to thrive and breed freely in proximity to civilisation. We must also take into account the increasing number of more or less domesticated animals which now enter largely into the fur trade, such as the so-called "Thibet" and other sorts of lambs, goat and dog skins, white rabbits from China, common cats from all countries, besides the finer lambs from Bokhara, Persia, etc., and rabbits from Australia and all parts of Europe.

There are 12 permissible trade names for various kinds of lamb skins used in fur manufacture, while the rabbit or coney boasts as many as 13 approved descriptions.

The coats of fur-bearing animals are at their thickest and best in winter and towards the close of the season are in the primest condition. All skins are brought to the market in the raw or undressed state, with the exception of some of the Chinese furs.

The dressing and dyeing of fur-skins has been gradually brought to a high state of perfection, the processes of which are carried on in most countries where there is a large consumption of furs. Certain work, however, is still confined to special localities: squirrels, for instance, have for many years been dressed and manufactured into linings almost exclusively at Weissenfels, near Leipzig, but also in Russia. London remains pre-eminent in the unhairing, dressing and dyeing of fur seals.

The prices of all furs, though fluctuating considerably from time to time according to supply and demand, have during the last eleven years been greatly enhanced, with few exceptions, though the figures in January, 1920, may be said to have represented the high-water mark of the fur trade. Taking the year previous to the war, 1913-14, as a standard of 100, the present value shows an increase of 100 per cent.

DISCUSSION.

The Chairman (Mr. Ernest Poland) said he was sure he was voicing the feeling of the audience in thanking the author for his most instructive paper, on which he must have bestowed a very great deal of care. In dealing with such a subject it was most difficult to concentrate into the small compass of an hour's lecture the very large amount of material which was available.

He drew the attention of those interested to a small volume which he had in his hands, entitled "Illustrations of Arts and Manufactures, being a selection from a series of papers read before the Society for the Encouragement of Arts, Manufactures and Commerce"—which was the full title of the Royal Society of Arts. The book had been published in 1841, and one of the lectures dealt with the subject of "Furs and the Fur Trade," delivered on the 26th January, 1830. No doubt, the volume found its place on the shelves of the Library of the Society, and anyone interested would be able to peruse it.

The Secretary thought it would be interesting if he read a footnote to the title of the paper to which Mr. Poland had referred. It read as follows:

> "For the splendid specimens of furs exhibited on this occasion, the Society is chiefly indebted to Messrs. Poland, of 21, Bow Lane."

Mr. Walter Martin said he recollected the last shipment of fur seals from the Pribilof Islands arriving in London to his old firm of Oppenheim and Co., in Bermondsey, in the year 1869. The date given in the paper with regard to the use of salt was 1868. He thought the furs to which he had just referred must have come in a salted state for a good many years before 1869, and consequently that the author was a little inaccurate in his date in that respect. The dyeing of fur seals in those days had been done chiefly by a man named Appold, who was an engineer, and who had invented the centrifugal pump by which some of the fens in Lincolnshire had been drained. He was rather proud of Appold having been in the fur trade, because it was Appold who had really enabled the first successful laying of the Atlantic cable. Appold had gone out on one of the vessels on which the cable had been broken away as it had been paid out, and he had suggested a certain method of retarding the cable and holding it up, thereby lessening the strain on the cable as it was paid out of the ship. The success in laying the cable had been really due to that suggestion.

The Chairman said there was one question he would like to ask. What did "sale by the candle" mean?

The Author replied that the candle used on such occasions had certain notches in it all the way down. A pin was put in at the notch. It took a certain number of minutes for the candle to burn down to the notch, and the last bid before the pin fell out secured the lot.

The Secretary remarked that, in common with a good many other people, he had always been troubled, when admiring the beautiful furs of beavers and such animals, by the idea that there was a great deal of cruelty involved in the trapping of those animals. He did not know whether or not that was so, and he would very much like to be informed. In such places as Northern Canada he understood traps were set which were only visited at fairly long intervals, with the result that animals caught in the trap soon after it was set, were kept in very great torture until they died. He would very much like some information on that point.

The Author said it was a very large and difficult question to answer. Right from the inception of things, traps had been used for catching animals. There was no unnecessary cruelty; there was no torture or anything of that sort. In a cold climate an entrapped animal did not live for many hours. A beaver caught under water could not live for many minutes because it could not breathe; its struggles were very quickly over. There was no torture employed by the Indian or by the native; he did not know so much about the white man, who had different methods entirely. That was shown in the course of the handling of the skins. Those in the trade could tell the difference immediately between an article handled by a white man and an article which had been handled by the natives; on the latter there was hardly a blood mark. The longest time a beaver could live under water without breathing was five minutes, and if it was struggling in a trap its breath would go very much quicker. If a native saw a beaver swimming right up out of the water he knew it was right to shoot it; but if it was swimming low in the water he knew it was carrying young and he did not shoot it. The native had so to farm his stuff that he could live next year and the year after that; he did not go out to kill anything and everything. He could not allow it to go forth that the native Indian or the native Eskimo allowed the least cruelty to be exercised in the prosecution of the trade. In his journeys he had seen nothing to which anyone could take exception.

Mr. Walter F. Reid, F.I.C., F.C.S., said he gathered from the paper that a very large number of squirrel skins were sent to Germany to be dressed, and he desired to ask why it was that such an industry was not promoted and carried on in this country, where there was plenty of chemical talent. Personally, he had had no difficulty for the last 50 years in dressing the skins which he had obtained, and he was sure there were a number of chemists here who were quite able to undertake similar work.

With regard to the future supply of furs, it was clear that many of the fur-bearing animals were dying out, but there was one animal now becoming numerous here, namely, the grey squirrel, which had spread all over the country and, from all accounts, was doing a considerable amount of damage. Personally, he had lost the greater part of his filberts last year through their ravages. For the last ten years he had been breeding cats for their fur, and he had now a breed of black cat without a speck of white on its fur, which fur was very like sealskin indeed. Of course, he would not dream of selling it for a sealskin, but still it was a very good warm fur with very thick hair. He had thought he could employ those cats in frightening away the grey squirrels, to which he had just referred, and he had therefore put them into the orchard where the filberts were. The following week he went down to see developments, and he had found the cats playing with the squirrels. It seemed, therefore, there was no obstacle to getting the grey squirrel to flourish in this country.

One thing ought to be impressed upon everybody who had to deal with fur-bearing animals, and that was to protect them during their breeding periods. It was good for the fur trade and for humanity at large that the great crime of exterminating those beautiful animals, which supplied civilisation with raiment, should not be allowed to be committed.

The Author, dealing with the question of protection, said the Canadian and other Governments had their close seasons for fur-bearing animals and on some occasions there was a complete cessation of killing for a period of years together. For instance, the Peru Government entirely protected the chinchilla and would not allow it to be exported.

The Chairman said, with regard to squirrels in this country, which had been mentioned by Mr. Reid, he believed they were the large grey American squirrels. They had multiplied enormously, but, unfortunately, their skins were too common for the fur trade, and it was not worth while encouraging the breeding of such animals.

Mr. G. Rice, dealing with the question of why skins were sent to Germany to be dressed, said prior to the year 1914 Great Britain, France and Germany, to name three of the principal fur trading countries, had each their own speciality in the preparation of various furs. France was particularly famous for the handling of musquash skins and rabbit skins. Owing to the acuteness of her chemists, France was able to prepare those skins better than Germany or any other country. Great Britain also had its own speciality, such as the handling of sealskins. Sealskins had always been handled, dressed and dyed for sale purposes in this country in a way superior to that of any other country. America and France had, with more or less success, tried to handle sealskins but they had never yet been able to equal the product of this country. Germany had played a very great part in pre-war days in the dressing and dyeing of furs. Her chemists were noted for their wonderful dyes, and French and English dyers had had to rely to a great extent on products from the German factories for their colours for furs. During the war, however, an enormous amount of raw skins, which in the ordinary way would have gone from this country to Germany for dressing and dyeing, had been kept in this country. The dressing and dyeing industry in this country had thereupon immediately started to expand and improve in every possible way. During the years of the war, and for two years afterwards, the dressers and dyers in this country had made very great progress. The dressing of squirrel skins had been particularly a German speciality in pre-war days, but now those skins could be dressed in this country quite as well as they had been in Germany. Unfortunately, however, owing to circumstances beyond control, that was to say, the fluctuation of currency and the depreciation of the German mark, quite a considerable amount of dressing and dyeing of furs had gone back to Germany. If the industry in this country was given the same chances as the German industry, he was quite sure it could not only equal, but beat the German industry in nearly every respect.

Votes of thanks to the lecturer and to the Chairman were then put and carried unanimously.

The Author, in acknowledging the vote of thanks, expressed his gratitude to the Chairman for the very great assistance and information which he had given him, especially with regard to the history of the trade. Mr. Poland was the head of a firm which had existed for over 140 years. It was one of the finest firms in the trade. Mr. Poland was a man who not only looked at the monetary side of the fur trade, but had always taken an interest in the zoological and technical sides of the industry.

THE CHAIRMAN in acknowledging the vote of thanks to himself, said he did not think he could tell Mr. Ingrams anything which Mr. Ingrams did not already know. But he had to admit that he was extremely interested in the historical and natural history parts of the subject as well as its other phases.

OBITUARY.

SIR HARRY JAMES VEITCH.—Sir Harry James Veitch, whose death took place on July 6th, was born at Exeter in 1840. After attending the Grammar School of his native city for a time he was sent, when 14 years old, to Altona, to study German, and later on he was placed with the well-known horticultural firm of Vilmorin, in Paris. Returning to London at the age of 18, he joined the business which his father had established in Chelsea, and which rapidly became well-known throughout the horticultural world by its enterprise in sending out collectors to secure new plants in the Far East, California, and South America.

The death of his father, in 1869, left the whole business in the hands of Mr. Harry Veitch, which under his management rapidly expanded. The hybridisation of orchids became a special branch in which he was very successful. The process of hybridising and of raising the seed had been a trade secret, but in 1884 Sir Harry decided to communicate his firm's knowledge to the world, and he read a paper before the Royal Horticultural Society in which the whole process was revealed.

Mr. Harry Veitch took a keen interest in organising the two great international Horticultural Exhibitions, the first of which was held in 1866 and the second in 1912. Both of these were extremely successful, and shortly after the latter, Mr. Veitch received the honour of a knighthood. He also received the Order of the Crown from the King of the Belgians, the French Legion of Honour, the Victoria Medal of Honour in Horticulture, the French Isidore St. Hilaire medal, and the United States George R. White gold medal for eminent services to horticulture. He was a corresponding member of almost every European and American horticultural society.

Veitch's "Orchidaceous Plants" and "Manual of Coniferae," both standard works, were compiled by him with the assistance of Mr. A. W. Kent, of his firm's staff. The *ampelopsis Veitchii*, one of the most popular of creepers, was introduced by him, and will keep his name green amongst gardeners for many generations.

Sir Harry Veitch was elected a Life Member of the Society in 1871, and he contributed £25 to the fund for purchasing the Society's House.

NOTES ON BOOKS.

INDEX TO "INDIAN ANTIQUARY."—Vols. I.-L. (1872-1921). Compiled by Lavinia Mary Anstey. Bombay: British India Press. To subscribers, *Indian Antiquary*, Rs.6, non-subscribers, Rs.9.

When, in December, 1921, that indispensable Journal, the *Indian Antiquary*, completed its fiftieth year, the Editor-Proprietor, Sir Richard Temple, announced that general indices to the existing volumes were under preparation. They have now been issued in three parts: Part I.—Authors' Index; Part II.—Subject Index; Part III.—Illustrations. Parts II. and III. form a separate volume. A large portion of the excellent subject-index is devoted to inscriptions, general, copper and stone, together with notes, including discussion of dates and identification of places. The hope expressed that the entries relating to inscriptions and the dynasties and eras concerned with them will be found specially valuable to students in the future cannot fail to be realised. From Sir R. Temple's explanatory pamphlet referred to above we learn that the *Indian Antiquary* has always been conducted on an honorary basis —a veritable labour of love. "No one has ever been paid for a contribution or as an editor, or as an assistant of the editors, while the proprietors have contributed towards the cost of the Journal, sometimes heavily, despite the assistance received from time to time by way of subscription for copies accorded by the Secretary of State for India, the Government of India, and its subordinate Governments, and by the Native Rulers." The founder of the *Indian Antiquary* was James Burgess; for some years it was jointly conducted by John F. Fleet and Sir R. Temple, who became sole editor-proprietor in 1892. In the period covered by the Index, the total number of contributors was 527, while nearly as many plates of inscriptions appeared in the Journal itself and upwards of six hundred in the *Epigraphia Indica*, a Government publication which for many years was produced as an official quarterly supplement of the *Indian Antiquary*. The agents of the Journal for Europe and America are Messrs. Bernard Quaritch, Ltd., 11, Grafton Street, New Bond Street, W.

BEET SUGAR AND FRUIT GROWING INDUSTRIES OF SLOVAKIA.

From the report on Slovakia and the Ruthene Territory by H.M. Consul at Bratislava, it appears that the beet sugar industry is of great importance. There are nine factories in Slovakia and their production in 1923 is stated to have been 1,033,826 quintals of crystallised and refined sugar and 106,165 quintals of raw sugar. Formerly this industry was highly protected. It has been established, notably in France, that the growing of sugar beet—because of the intensive use of fertilisers and the careful weeding which it involves

—improves the soil to such an extent that it yields as much as before plus, during the same period, a crop of beet. To encourage this cultivation the late Austro-Hungarian Government enabled the manufacturers to export their surplus production at less than cost price, without regard to the home demand. Now, however, the price of sugar in the home market is fixed by the Government at a comparatively low figure, and only the surplus over the home demand may be exported. The principal profit therefore has to be made in open competition in the world's market. In 1923 all the factories in Slovakia did well.

Fruit growing in Slovakia, says the Consul, might be developed into a profitable export business. A census of fruit trees held in 1920 showed that there were then in this part of the country about 2,820,000 plum, 1,250,000 apple, 770,000 pear, 640,000 cherry, 335,000 nut, and 120,000 apricot trees.

The Government is encouraging the cultivation by maintaining six technical schools for fruit farming. It distributed besides, in 1923, 30,000 young trees at a nominal cost. Fruit has, so far, been chiefly grown for the purpose of distilling spirits. Though fresh fruit is supplied to markets near at hand this is not a very profitable business and frequently it has to be used for feeding pigs or is allowed to rot unpicked. A trial consignment to England in 1923 proved a failure owing to the total lack of experience in packing. Until proper methods are adopted British importers would be ill-advised to allow themselves to be tempted by low quotations.

ASPHALT IN CUBA.

Seepages of oil and liquid asphalt and veins and deposits of solid asphalt are found throughout the whole length of Cuba in all the six provinces. The best known and most developed of the solid asphalt mines writes the Acting British Consul-General at Havana, is situated near the port of Mariel, some 35 miles west of Havana. This property, which covers a very large area, is owned by a British company, and is operated under the direction of a British firm of mining engineers. Difficulties of transport and finance have tended, together with other factors, to retard the development of this mine. However, it is estimated that 70,000 tons of asphalt had been mined and shipped from Mariel prior to 1914. During the war operations were suspended, and were not renewed until 1919, when one of the the veins was attacked by a shaft and underground galleries at a depth of 200 feet. At this depth the vein has so far been opened up for a length of 700 feet, varying from 25 to 35 feet in width. It has been traced on the surface for over 3,000 feet by open pits, and at one point shows a maximum width of 70 feet. A bore hole on the vein showed asphalt at 450 feet.

Since this vein is only one of many known veins on the property it is apparent that the owners have an almost inexhaustible supply of material.

The same company owns valuable asphalt properties in the province of Havana and at Bahia Honda, Pinar del Rio, neither of which is being operated at present.

In the Bay of Cardenas are large deposits of a remarkably pure bitumen, and about 30,000 tons have been extracted without appreciably reducing the deposit, which is fed by springs from below.

Near Cardenas there are also wells that produce 20 barrels of liquid asphalt per day. For this liquid asphalt there is a great opening for use as a fluxing material for the solid asphalts.

The Mariel mines are operated entirely by power produced from burning the asphalt.

GENERAL NOTES.

◆

Manufacture of Knitted Bead Slippers in Germany.—The production of hand-knitted bead slippers, writes the United States Consul at Stuttgart, has been recently attempted in Germany, but the cost has proved too high and the process too slow for practical purposes. However, a firm in Stuttgart is now experimenting with a knitting machine which will enable the production of such slippers on a large and profitable scale, and the machine-made bead slippers will be more evenly and perfectly finished than if the beads are strung and knit by hand. The cost of producing a pair of machine-knitted bead slippers is estimated at £2 12*s*. It is expected that as soon as the problem of suitable machinery has been solved, and the slipper once introduced on the world markets, it will attract wide attention and become universally adopted as a high-class dress slipper.

The Trade of Kenya and Uganda.—The foreign trade of Kenya and Uganda in 1923 shows great progress during that year. Trade imports are valued at £4,302,574, or over £1,420,000 above the figure for 1922, while produce exported, valued at £3,996,432, shows an increase of £1,215,000 over the total for the previous year. The value of coffee shipments rose from £579,061 in 1922 to £620,897 in 1923; of maize exports from £148,910 to almost £250,000; of hides from £50,000 to over £118,000; while sheep and goat skins increased from £23,420 to £34,328. Cotton-seed exports increased from £14,000 to nearly £55,000, and simsim reached the high total of £67,550; but there was a decline in linseed from £7,700 to about £3,800.

MEETING OF THE SOCIETY.

◆

Dominions and Colonies Section.

Thursday, July 24, at 4.30 o'clock:—M. Franck, late Colonial Minister of the Belgian Government, "Recent Developments in the Belgian Congo." The Hon. W. Ormsby-Gore, M.P., will preside.

Journal of the Royal Society of Arts.

No. 3,740. VOL. LXXII.

FRIDAY, JULY 25, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICE.

◆

COMPETITION OF INDUSTRIAL DESIGNS.

An Exhibition of selected works submitted at the Society's Annual Competition of Industrial Designs will be held, by the courtesy of the Director, in the North Court of the Victoria and Albert Museum, South Kensington, S.W., from Saturday, July 26th, to Saturday, August 30th (both inclusive). The designs exhibited are divided into the following classes: Textiles, Furniture, Book Production, Pottery and Glass, and Miscellaneous. The Exhibition will be open to the public free.

The Reports of the Judges, including the awards of prizes have now been received, and it is hoped to publish them in the *Journal* at an early date.

PROCEEDINGS OF THE SOCIETY.

◆

EXTRA MEETING.

WEDNESDAY, JULY 2ND, 1924.

MR. ALAN A. CAMPBELL SWINTON, F.R.S., late Chairman of the Council, in the chair.

THE CHAIRMAN said it was quite unnecessary to introduce the lecturer, for throughout the whole civilised world there was no leader in applied science better known than Senator Marconi. He thought the Society could congratulate itself on the fact that Senator Marconi had chosen that place to read a paper which, he thought, time might show to be a landmark in the history of wireless telegraphy. Two letters had been received which he would like to read, expressing regret for inability to be present—one from Lord Balfour, who still signed himself, "A.J.B.":

"My dear Senator Marconi,—There is nothing which would have interested me more than your lecture on 'Short-wave Directional Wireless,' and I am in despair at not being able to go. But you will understand the position when I tell you that as President of the British Academy I have to preside at our Annual General Meeting on the afternoon of July 2nd, at the very hour at which you are lecturing at the Society of Arts. It is very unfortunate."

The other was from the Secretary to the Prime Minister: "Dear Sir,—The Prime Minister has asked me to thank you for your kind letter of 27th June, and to say that it would have given him great pleasure if he had been able to come to your lecture on 2nd July. It is very, very difficult for him to get away in the afternoons when the House of Commons is sitting, and unfortunately on Wednesday afternoon it is imperative for him to be present in the House. The Prime Minister is very sorry to have to decline your kind invitation in these circumstances, but he knows that you will understand what his difficulties are."

The following paper was then read:—

RESULTS OBTAINED OVER VERY LONG DISTANCES BY SHORT WAVE DIRECTIONAL WIRELESS TELEGRAPHY, MORE GENERALLY REFERRED TO AS THE BEAM SYSTEM.

By SENATOR GUGLIELMO MARCONI, G.C.V.O., LL.D., D.Sc.,

A Vice-President of the Society.

The study of short electrical waves dates from the time of the discovery of electric waves themselves, that is, from the time of the classical experiments of Hertz and his contemporaries, over thirty-five years ago; for Hertz used short electric waves in all his experiments when he conclusively proved that these waves obeyed the same laws as the waves of light in regard to speed of propagation, reflection, refraction and diffraction.

I might also, perhaps, recall the fact that when I first came to England, over 28 years ago, I was able to show to the late Sir William Preece, then Engineer-in-Chief of the Post Office, the transmission and reception of intelligible signals over a distance of 1¾ miles of a beam system employing short waves and reflectors, whilst, curiously enough, by means of the antenna or elevated wire system I could only get signals, at that time, over a distance of half a mile.

Many years afterwards, through the courtesy of the Post Office, I was favoured with a copy of the Official Report of those early tests, which, from an historical point of view and in regard also to latest developments, makes now most interesting reading.

The progress subsequently made with the long wave system was, however, so rapid, so comparatively easy and so spectacular that it diverted all research from the short waves, and this, I think, was regrettable, for it has only recently been discovered that these waves, which alone can be in practice confined in beams to definite directions, are capable of results unobtainable by the use of the lower frequency system which up to now has held the field for long distance radio communication.

The late Sir William Preece described my early tests at a meeting of the British Association for the Advancement of Science, in September, 1896, and also at a lecture he delivered before the Royal Institution in London on the 4th of June, 1897.

On the 3rd of March, 1899, I went into the matter more fully in a Paper I read before the Institution of Electrical Engineers, to which Paper I would recall your attention as being of some historical interest.

At that lecture I was able to show that it was possible, by means of short waves and reflectors, to project the rays in a beam in one direction only, instead of allowing them to spread all around, in such a way that they could not affect any receiver which happened to be out of the angle of propagation of the beam, and I described tests carried out before the Post Office Engineers at Salisbury Plain, pointing out the possibilities of such a system if applied to lighthouses and lightships, in enabling vessels in foggy weather to locate dangerous points around the coasts.

I also showed results obtained by a reflected beam of waves projected across the lecture room, and how a telegraphic receiver could be actuated or a bell rung only when the aperture of the sending reflector was directed towards the receiver. (Figs. 1 and 2.)

Since those early tests of over twenty-five years ago, and for a very long period of years afterwards, so far as I can ascertain, practically no research work was carried out, or at least published, in regard to the application of very short waves to radio communication.

Research along these lines did not appear easy or promising; the use of reflectors of reasonable dimensions implied the use of waves of only a few metres in length which with the means then at our disposal were difficult to produce, and up to a comparatively recent time the power that could be radiated by them was small. This, and the supposed high attenuation of the waves over any distance of land or sea, gave results which appeared to be rather disappointing.

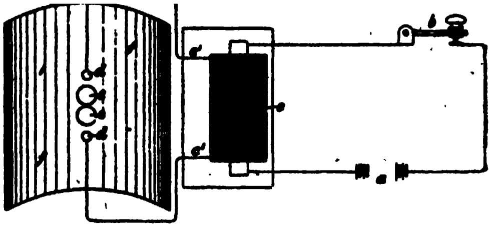

FIG. 1.—Spark Transmitter and Sheet Metal Reflector, 1896.

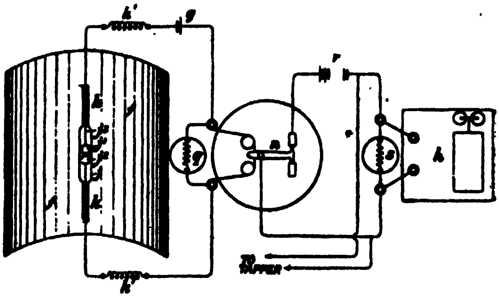

FIG. 2.—Coherer Receiver and Sheet Metal Reflector, 1896.

Some years ago, during the War, I could not help feeling that we had, perhaps, got into a rut by confining practically all our researches and tests to what may be termed long waves, that is, waves of some thousands of feet in length, especially as I remembered that during my very early experiments, in 1895 and 1896, I had obtained promising results over short distances with waves not more than a few inches long.

The investigation of the subject was therefore again taken up by me in Italy early in 1916 with the idea of utilising beams of reflected waves for certain war purposes, as I was greatly impressed with the advantages which such a system would afford in minimising tapping or interception by the enemy, besides greatly reducing the possibility of interference with our own stations.

At subsequent tests during that year and afterwards I was most valuably assisted by Mr. C. S. Franklin.

The Royal Italian Navy also gave me

all possible facilities for the carrying out of my tests in Italy.

Mr. Franklin since then followed up the subject with great thoroughness, and results of his investigations were described by him in an admirable paper read before the Institution of Electrical Engineers on the 3rd of April, 1922.

At a lecture delivered by me before a joint meeting of the American Institute of Electrical Engineers and the Institute of Radio Engineers in New York, on the 20th of June, 1922, in which I described the results obtained up to that time by Mr. Franklin and myself, I felt I could not but express the opinion that it was most regrettable that the study of the characteristics and properties of short waves and their adaptability to directive methods had been so sadly neglected, and pointed out that very many important problems in radio transmission could only be solved by the use of the short wave directional system.

The reflectors now used for this system are not composed of solid sheets of metal, such as those employed in my early tests in 1896, but of a comparatively small number of wires placed parallel to the antenna and spaced around it on a parabolic curve of which the transmitting or receiving antenna constitutes the focal line (Fig. 3), as it was soon ascertained that this was a much more practical arrangement, and that, moreover, much better results could be achieved.

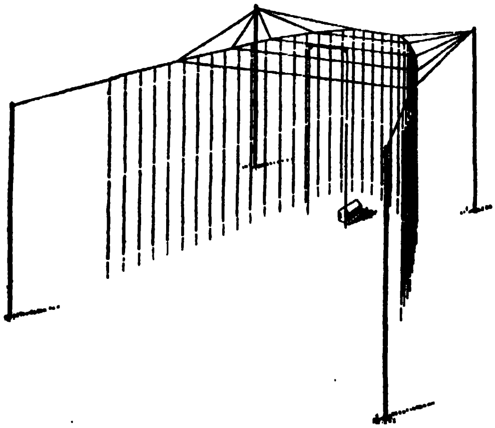

FIG. 3.—Parabolic Vertical Wire Reflector, 1923.

Suggestions for using reflectors of this kind were made by Brown, in 1901, and by De Forest, in 1902, but many essential conditions necessary for efficiency were apparently not realised by these workers at that time, which probably explains why no application of their arrangements was made for practical purposes.

Since 1916 various patents have been taken out by myself and Mr. C. S. Franklin, and in the latest of these Mr. Franklin describes an arrangement in which the antennæ and reflector wires are arranged so as to constitute grids parallel to each other, the aerials or antennæ being energised simultaneously from the transmitter at a number of feeding points through a special feeding system, so as to ensure that the phase of the oscillations in all the wires is the same. It has been proved by calculations confirmed by experiments that the directional effect of such an arrangement is a function of its dimensions relative to the wave length employed. (Fig. 4.)

During my tests of 1916 I used a coupled spark transmitter and the receiver was a crystal receiver. The reflectors employed were made of a number of wires tuned to the wave used, arranged on a cylindrical parabolic curve with the aerial in the focal line.

Reflectors with apertures up to 3½ wave lengths were tested, and the measured polar curves agreed very well indeed with the calculated values.

The Italian experiments showed that good directional working could always be obtained with reflectors properly proportioned in respect to the wave length employed, and with the apparatus then available the range obtained was six miles.

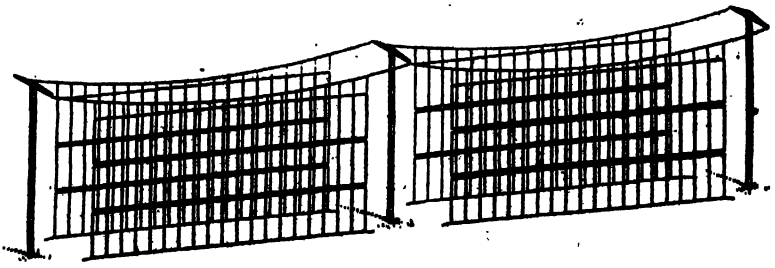

FIG. 4.—Vertical Wire Flat Transmitting Aerial and Reflector, 1924.

The tests were continued in Wales at Carnarvon during 1917, and through the introduction of further improvements, with a wave length of three metres, a range of over 20 miles was readily obtained when using a reflector at the transmitting end only.

In 1919 further experiments were commenced in which Mr. Franklin succeeded in using electron tubes or valves for the generation of very short waves, the object then being to evolve a directional radio-telephonic system.

During further tests, and by utilising a 15 metre wave, clear and strong speech was received in Kingston Harbour, at a distance of 78 miles from Carnarvon.

At a later date these tests were repeated over a land range of 97 miles between Hendon and Birmingham. The power supplied to the valves was approximately 700 watts, and the speech received was strong and of good quality.

The great value of the reflectors was demonstrated by average measurements made, which showed that the value of the energy received when both reflectors were used was 200 times that of the energy that could be received without reflectors.

In April, May and June of last year a series of long distance tests were carried out under my direction between a small experimental transmitting station at Poldhu in Cornwall and a receiver installed on the S.Y. "Elettra."

Mr. C. S. Franklin was responsible for most of the design and operation of the transmitting arrangements at Poldhu, and Mr. G. A. Mathieu was in charge of the receiving apparatus on the yacht, where I also was present during the whole of these tests. Mr. Mathieu was able to make some valuable calculations based on the observed results, especially in regard to the absorption or attenuation of the waves brought about by sunlight.

The principal objectives of these tests were :—

(1) To ascertain the reliability of signals transmitted on approximately a 100 metre wave over considerable distances with or without the use of a transmitting reflector.

(2) To investigate the conditions which affect the propagation of short waves, and to ascertain the maximum reliable ranges obtainable by day and by night in respect to the power and wave length employed at the sending station.

(3) To investigate and determine the angle or spread of the beam of radiation when employing a transmitting reflector, especially with regard to the possibility of establishing long distance directional wireless services.

During the tests carried out on the S.Y. "Elettra" no receiving reflector could be employed, and it will therefore appear obvious that the strength of the received signals and the ranges covered must have been considerably less than could have been obtained had it been possible to use a fixed receiving station equipped with a suitable reflector.

Up to the present time the general impression prevailing amongst most technical experts in regard to the behaviour of short waves is :—

(1) That their range during day time is variable and short.

(2) That the night ranges are exceedingly variable and freaky, and altogether too unreliable to allow of the carrying out of commercial work.

(3) That any considerable amount of intervening land or mountains very seriously reduces the distance at which it is possible to communicate.

The tests carried out between Poldhu and the "Elettra" proved by the definite results obtained that the above mentioned impressions or conclusions must be erroneous, at least in so far as they may concern waves of about 100 metres long, for we observed :—

(1) That the day ranges proved to be reliable and not inconsiderable.

(2) That the night ranges were much greater than anyone, myself included, had anticipated, and no doubt very considerably exceeded the maximum distance to which I was able to proceed with the "Elettra."

(3) That intervening land and large portions of continents do not present any serious obstacle to the propagation of these waves.

In carrying out these tests we discovered that it is by no means correct in dealing with these waves to refer to distances covered during daylight as day-ranges, as the strength of the signals which can be received during the hours of daylight varies definitely and regularly in accordance with the mean altitude of the sun over the space or region intervening between the two stations.

This discovery, based on the observed results makes it safe to infer that our tests which took place mainly during the months of May and June, and partly within the tropics, were carried out at the most unfavourable time of the year for daylight transmission (as the sun reaches its maximum altitudes during June in the Northern Hemisphere) and over what is a most difficult region.

Perhaps one of the most remarkable scientific results of the experimental work carried out on my yacht was to ascertain quite definitively that the coefficient of the well known Austin Formula for the propagation of the waves was defective when applied to short wave phenomena.

It will be remembered that this absorption factor is an exponential of the form e^{-x}, where -x the negative index is given by Austin as the product of a constant multiplied by the ratio of the distance between the stations and the square root of the wave length used.

Slightly modified values for that constant have been suggested by several scientists during recent years, and a different value has also been suggested for daylight and night communication.*

The results of our measurements and observations are that for short waves of the order of 100 metres this constant must be replaced by a variable, which is approximately a linear function of the mean altitude of the sun calculated on the great circle track between the two stations.

In other words, the coefficient of absorption is a function of the time, the seasons and the relative geographical situation of the stations, and can now easily be ascertained for wave lengths of the order of 100 metres.

Our tests obviously show that short waves behave quite differently in their propagation from long waves, and that the weak period at sunset and sunrise followed by a recovery in signal intensity observed with the long waves over great distances, is not true in the case of short waves.

It also appears that there is probably no sharp limit between short and long waves, and that the change in the behaviour of short waves, of say 100 metres, to that of long waves of, say 10,000 metres, may follow a slow process of transformation.

Very likely over very long distances as the wave length increases there may be a tendency for the signals to recover progressively during the period of no signal, for short waves, and this may form the object of further very interesting investigation.

In regard to the x's and atmospheric disturbances generally, these usually appeared to be, during day time, less severe than those experienced when working with the longer waves up to now employed for practical radio telegraphy.

During night-time, even when receiving at St. Vincent, which is situated at 2,330 nautical miles from Poldhu, and well within the tropics, the strength of received signals was so great that absolutely none of the x's or atmospherics which we there experienced ever approached being able to interfere in any way with the reception of signals or messages from Poldhu.

During the tests to the "Elettra" on 97 metres wave the Poldhu transmitter consisted of 8 glass valves (standard M.T.2) worked in parallel, the input to the valves being 12 kwtts. The radiation from the aerial was approximately 9 kwtts. The parabolic reflector concentrated the energy towards Cape Verde and gave a strength of field in that direction which would have required a radiation of approximately 120 kwtts. from the aerial without a reflector to produce.

For the purpose of the experiment a special receiver with independent aerial was installed and added to the wireless gear of the "Elettra."

The receiving aerial was a vertical wire, the top of which was at a height of 20 metres above sea level.

The receiver consisted of an aerial circuit, a closed condenser intermediate circuit, a frequency changer circuit, two high frequency tuned amplifications and an autoheterodyne detecting valve to which could be added two stages of low frequency amplification.

After carrying out a few preliminary tests in Falmouth Harbour on the 11th April, the "Elettra" sailed for Cape Finisterre (Spain).

A first series of tests was carried out without the transmitting reflector.

After rounding Cape Finisterre it was anticipated that the intervening land would have cut off signals during daytime and also would have considerably weakened them during the night.

These expectations were not verified.

Signals during the day weakened according to the distance and the altitude of the sun, but were received right up to Seville (780 miles from Poldhu) although practically the whole of Spain, consisting of over 300 miles of high and mountainous land, intervened between the sending and receiving stations.

---

*Based on the so-called night effect, which I discovered early in 1902. (See Proceedings of the Royal Society, Vol. LXX., by G. Marconi, June 12th, 1902.

The night signals were always so strong as to appear almost as powerful as those received when the yacht was at her anchorage in Falmouth Harbour at only 12 miles from Poldhu.

It should be stated that the yacht, when at Seville, was moored in the Guadalquivir River, in a situation particularly unfavourable for the reception of signals, as the adjacent banks of the river were high and surrounded by trees and buildings.

At Gibraltar (820 miles), notwithstanding the greater distance, a better strength of signals was noticed during the hours of daylight, probably in consequence of the fact that the yacht was anchored in a more open space, and therefore in a more favourable position.

Similar results were also obtained at Tangiers (840 miles) and at Casablanca (970 miles).

I find it almost unnecessary to refer to the night signals, as these were always, and in all places throughout the whole of the cruise, extraordinarily strong and capable of being received at all times without using an amplifier, with the aerial out of tune, or disconnected, or without using the heterodyne.

At Casablanca I telegraphed instructions to hoist the reflector aerials at Poldhu.

The " Elettra " then proceeded to Madeira, but at Funchal was obliged to anchor in a very unfavourable position for the reception of wireless signals from England, being at the far end of the island and immediately under the mountains of Madeira, some of which rise to heights of over 6,000 feet.

On the 17th of May tests were recommenced between Poldhu and the " Elettra," but although the night signals were, as always, extremely strong, I considered it desirable to carry out daylight tests in positions not so completely screened by the immediate vicinity of mountains.

Thus it was ascertained that signals could be received from Poldhu by day up to 1,250 nautical miles when that station was using 12 kwtts. of energy.

On the 21st of May we sailed for St. Vincent, Cape Verde Islands, and although at St. Vincent our anchorage was at a position partly screened by mountains, daylight reception was still possible for a few hours after sunrise and for some time before sunset.

The night signals continued to arrive from Poldhu at all times with apparently unabated strength, notwithstanding that our distance had increased to about double what it was at Madeira, that is, to 2,230 nautical miles.

At St. Vincent, as at Madeira, the Poldhu signals could always be received with the heterodyne or l.f. amplifier switched off.

Mr. Mathieu estimated the strength of the night signals at St. Vincent from 400 to 500 microvolts per metre in the aerial, and with such a strength on the wave length we were using, no trouble was ever experienced in consequence of atmospherics or x's. In fact, for greater convenience, all messages from Poldhu were read with the aerial out of tune or disconnected from the receiver.

At St. Vincent the signals received from the Post Office at Leafield were weak and often unreadable. I therefore gave instructions that all wireless messages addressed to me should be transmitted by our short wave experimental station at Poldhu. No difficulty was ever experienced in the accurate reception of these messages.

As, in consequence of my having to return to England, it was decided not to carry on these tests to still greater distances, I instructed Poldhu to gradually reduce the transmitting power from 12 kwtts. down to 1 kw., but even with this small amount of energy the signals received at St. Vincent were still stronger than would have been necessary for the carrying out of commercial work over that distance.

Mr. Mathieu calculated that the signals would still have been readable at St. Vincent, even should the power at Poldhu have been reduced to 1-10th of a kilowatt.

I might add that the night signals received at St. Vincent, even when Poldhu was using only 1 kilowatt, were much stronger than those received from Carnarvon, or than those which could be received at either St. Vincent or Madeira from any of the other European or American high-power stations.

The signals by night or by day did not appear to be subjected to lengthy fluctuations in strength, nor inclined to give what have been termed freak results. The results obtained could always be repeated over the same distances under similar conditions in respect to the sun's altitude.

Short periodical fluctuations of strength, lasting less than a minute, were constantly observed, but I believe that these variations were mainly caused by slight changes of the wave length determined by imperfections of the arrangements in use at Poldhu, and also by the movements and rolling of the ship at the receiving end.

Although sunrise at St. Vincent occurred about three hours later than at Poldhu, during the period of the tests nothing was observed which would indicate the existence of the weak period so noticeable under similar circumstances in radio reception between Europe and North America.

The results of these tests were sufficient to convince me that it would be possible to carry out reliable commercial services for a large portion of hours out of the 24 over distances of at least 2,300 nautical miles by utilising only about 1 kilowatt of energy at the transmitting stations, and that the practical range of the system, when using 12 kilowatts had not even been approached.

These results were obviously so encouraging that I decided to give the new system very careful study and consideration.

The station at Poldhu was somewhat improved, and the energy employed was increased to about 20 kilowatts.

Since February of this year a further series of tests have been carried out over ranges which included the greatest possible distances separating any two places on earth.

A special short wave receiver was installed on the S.S. "Cedric," and reception tests were carried out with Poldhu by Mr. Mathieu during a journey of this vessel to New York and back. No reflectors of any kind were employed at either end.

For the tests to the "Cedric" the wavelength was 92 metres and the transmitter comprised two oil-cooled valves of special design controlled by an independent drive circuit to ensure steadiness of wave-length. The power supplied to the main valves was 21 k.w. giving a radiation of approximately 17 k.w.

These experiments were conducted with the object of supplementing our information on the general behaviour of short waves over long distances.

The results showed that on the "Cedric" signals could be received during daytime up to a distance of 1,400 nautical miles, and it was confirmed that the signals' intensity is symmetrical to the mean altitude of the sun at all times. As a consequence of this, the day limit of the signals on the "Cedric" was greater than what was observed during the cruise of the "Elettra" because the average height of the sun was much less at that time of the year on the particular track of the "Cedric" compared to what it was on the far more southernly track followed by the "Elettra" during the months of May and June.

Signals of great intensity were received at Long Island, New York, during the hours when darkness extended over the whole distance separating the stations, and of less intensity when the sun was above the horizon at either end, the intensity of the signals varying inversely in proportion to the mean altitude of the sun when above the horizon.

According to the measurements carried out Mr. H. H. Beverage, Research Engineer of the Radio Corporation of America, the average strength of the signals at New York was 90 microvolts per metre.

I might mention that a few days prior to the commencement of these tests between Poldhu and the "Cedric," the Chief Engineers of the Amalgamated Wireless (Australasia) Ltd., of the Marconi Wireless Telegraph Company of Canada, Limited, and of the Radio Corporation of America, had been requested by telegraph to attempt to receive the transmissions radiated from Poldhu in their respective countries.

Rather to my surprise, I must admit, Mr. Ernest T. Fisk, the Managing Director of the Amalgamated Wireless (Australasia) Ltd. reported to me by cable that he could receive the Poldhu transmissions at his house in Sydney every day perfectly well from 5 to 9 p.m. (Greenwich) and also that he had received them between 6.30 and 8.30 a.m., informing me also that for most of the time the signals were clear, steady and strong on an improvised receiver consisting of a 2-stage high frequency tuned plate and grid with one rectification. He also added that he had read every word that was sent and that the signals were better than those he had yet received from the high power station at Carnarvon.

These experiments with Australia were continued during the month of May, consistently good results being obtained at two receiving stations situated in the vicinity of Sydney.

It seems obvious, if we consider the position and altitude of the sun, that during the morning period the waves travelled from England to Australia starting in a westerly direction, across the Atlantic and Pacific Oceans, along the longest route, which is approximately 12,219 nautical miles, whilst during the evening period they travelled in an easterly direction over Europe and Asia, along the shortest route, which is about 9,381 nautical miles.

In Canada, at Montreal, reception was found to be possible for 16 hours out of the 24.

These results were so encouraging that I was tempted to try a wireless telephony test to Australia.

With rather experimental arrangements at Poldhu, intelligible speech was transmitted for the first time in history from England to Sydney on Friday, the 30th day of May, of this year.

For the telephone test to Australia, oil-cooled valves were employed for the main valve and for modulating valves. The wave length was 92 metres and an independent drive was employed for controlling the main valves. The total power supplied to the valves was approximately 28 k.w. divided up as follows : 18 to the main valves, 8 to the modulating valves and 2 to the drive valves. No reflector was employed.

A continuous development of the short wave transmitter has been taking place at Poldhu. To utilise considerable power, required the study and development of circuits for paralleling valves satisfactorily, and also the design of special valves. To maintain the wave length steady has necesitated the application and development of an independent drive. These problems have been solved satisfactorily and the production of commercial transmitters dealing with powers up to the order of 50 k.w. now presents no difficulties. Figs. 5 and 6 show the interior and exterior of the small experimental station at Poldhu.

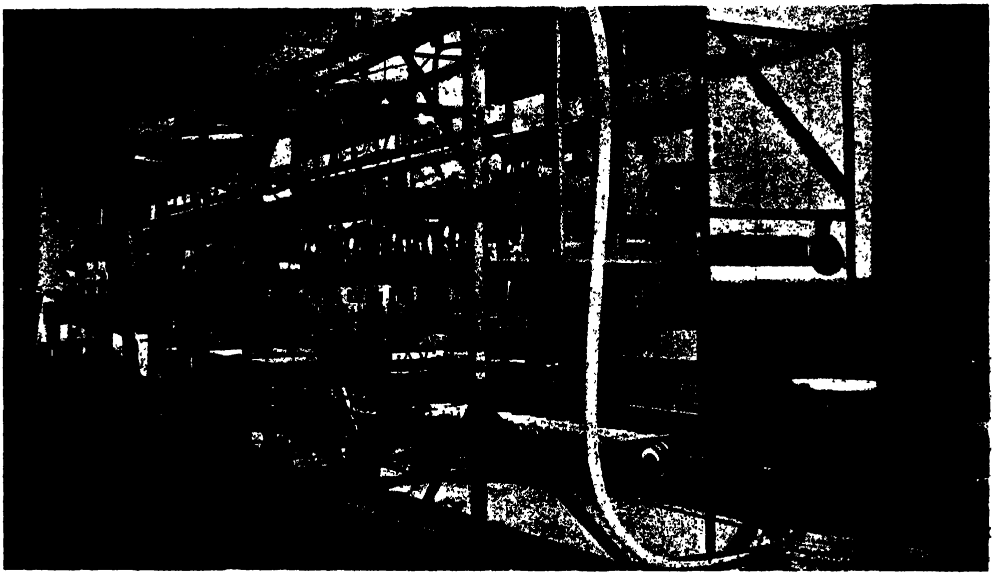

FIG. 5.—Experimental Poldhu Transmitting Plant, 1924.

FIG. 6.—Experimental Transmitting Hut, Poldhu, 1924.

It was gratifying to all concerned that the experiment succeeded the very first time it was tried, Mr. C. S. Franklin being in charge of the transmitting apparatus at Poldhu and Mr. Ernest T. Fisk of the receivers at Sydney.

It is also interesting to observe that these extreme distances were obtained without the use of any reflector at either end.

The results obtained between England and Australia easily constitute a record for ratio of distance to wave length, for Sydney, by the shortest route, is approximately 189,000 wave lengths from Poldhu.

In my opinion it appears to have been proved conclusively that adequately designed reflectors, even if of comparatively moderate size, will enormously increase the effective strength of the signals.

This cannot but augment the efficiency of communication, besides increasing the number of hours during which it will be possible to work with very distant countries.

Moreover, the use of receiving reflectors will be of the greatest advantage to practical working, because whilst magnifying the strength of the received waves they reduce all interference whether caused by atmospheric electricity or other stations, unless, of course, the direction from which the interference may be coming happens to coincide exactly with that of the corresponding station.

The energy magnification, due to the concentration of the energy by the directional effect, has been carefully calculated by Mr. Franklin, and tests carried out at Poldhu have fully confirmed his figures.

FIG. 7.

Fig. 7 shows comparative polar diagrams of the field in all directions from three different transmitters. The circle is a polar curve of a plain non-directional aerial. The short dot curve shows the polar curve of a two-wave length aperture reflector. The long dot curve shows the polar curve of an 8-wave aperture reflector, such as we propose to use for practical purposes.

The case which was tried experimentally at Poldhu was an aerial and reflector ½ wave high 3 waves wide, the aerial being fed at four points with a cable feeder system. The horizontal polar magnification figure of about 30 was found.

Mr. Franklin has formulated some general laws regarding these aerials, which may be stated as follows :—

(1) The ratio of the loss by radiation to the loss by ohmic resistance, and therefore the efficiency remains constant for all sizes of the aerial at the same frequency. This efficiency figure is very high and can easily be of the order of 80%.

(2) The natural decrement of the aerial is very high, and remains constant whatever the extension, as the ratio of the inductance to the resistance of the aerial remains the same.

(3) The greatest magnification for a given area, and therefore for a given cost, is obtained by having equal areas at the transmitter and receiver. Thus an aerial of 20 square wave lengths at transmitter and receiver gives a magnification of 200, but if divided into two aerials at transmitter and receiver, each of 10 square wave lengths, gives a magnification of 10,000.

(4) For a given area of aerial at the transmitter and receiver, the magnification goes up as the fourth power of the wave frequency used. Thus, assuming aerials 1 kilometre wide and one hundred metres high at transmitter and receiver, these would each be 10 square wave lengths for 100 metre wave and would give a combined magnification of 10,000. For half this wave length (50 metres) each aerial would be 40 square wave lengths and would give a combined magnification of 160,000.

Up to what ranges this fourth power law can be effective in compensating for the greater attenuation of the shorter wave has yet to be ascertained.

The energy capacity of these aerials is enormous and they could never conceivably be worked to their limit. It would be quite possible practically to superimpose several waves and thus several services on the same aerial.

It should not be lost sight of that very high speeds of working appear to be possible only if short waves are employed, whilst speeds of the same order are quite unattainable with the long waves now in general use for long distance radio communication.

I might, in other words, state that there exists no theoretical reason why with a frequency of 3,000,000, such as is the frequency of oscillation of a 100 metre wave, the speed should not be one hundred times as great as the speed attainable with a frequency of 30,000, which represents the frequency of a wave length of the order of those which it is proposed to use for the Imperial Stations.

Between the 12th and the 14th of June (both inclusive) of this year, some further important tests were carried out between Poldhu and a small receiving station at Buenos Aires in the Argentine, the distance between the two points being 5,820 nautical miles (10,780 kilometres).

Although many of the arrangements employed were far from perfect, very strong signals were received for over ten hours each day at Buenos Aires.

Messages were sent by the Argentine Minister of Agriculture, Dr. Le Breton, who happened to be in London, to the Minister of War, General Justo, in the Argentine, and every message transmitted was correctly received in one transmission.

At the conclusion of the tests we received a communication from the Argentine Committee, representing the wireless interests in the Argentine, who are conducting the wireless telegraph services through their super-power station with Europe and the United States of America, to the effect that the signals from Poldhu transmitted by this new system were received at Buenos Aires with such regularity and extraordinary strength as to permit a service being conducted at any speed, and expressing the opinion that the Argentine station should be immediately equipped with the new system, which, they are confident, will handle more than double the traffic in six hours than they are now able to handle in twenty hours with their present super-power station. Excellent results were also obtained at Rio in Brazil. (Fig. 8.)

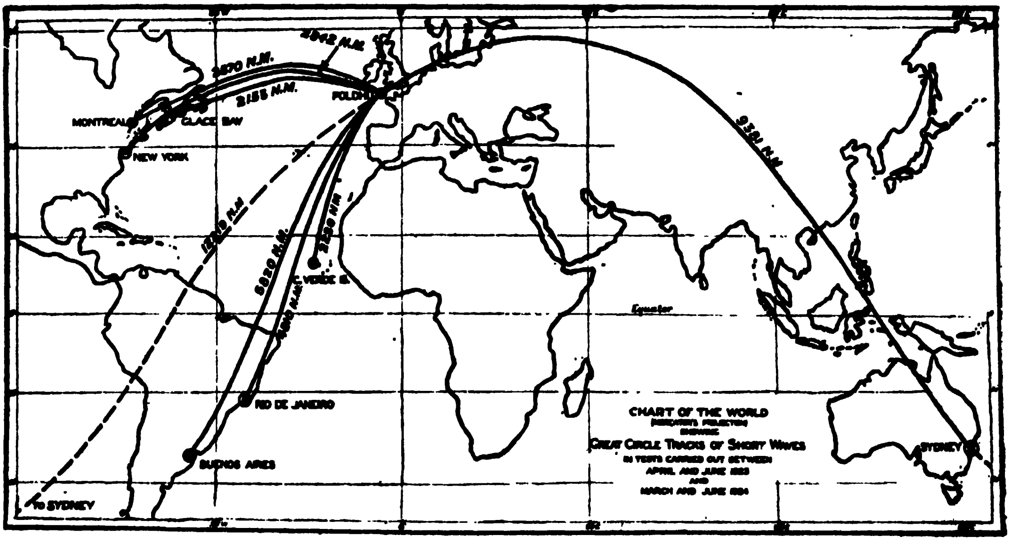

FIG. 8.

For this radio-telegraphic test the wave length was 92 metres and the power to main valves was 21 k.w. This gave a radiation of 17 k.w. The parabolic reflector was employed to concentrate the energy towards South America, and gave a strength of field in that direction which would otherwise have required a radiation of approximately 300 k.w. from the aerial without reflector to produce the same effect.

All these results, many of which have greatly exceeded my expectations, convince me that by means of this system economical and efficient low power stations can be established which will maintain direct high speed services with the most distant parts of the globe during a considerable number of fixed hours per day.

I am further of the opinion that by means of these comparatively small stations a far greater number of words per 24 hours could be transmitted between England, India and her distant Dominions than would be possible by means of the previously planned powerful and expensive stations.

Another particular advantage of this system should not be overlooked. As distant stations situated only within a certain angle or sector of the beam are enabled to receive, this condition brings about a comparative privacy or secrecy of communication unobtainable with any other system of radio communication, and this may prove to be of the greatest value in war time, besides considerably increasing the number of stations it will be possible to work, by reducing the possibilities of mutual interference between them.

The comparative economy in capital cost of these stations, the small amount of electrical power which need be employed, together with the capability of working at very high speeds, should make it possible to bring about a substantial reduction in telegraphic rates. The importance of this to the Empire must be obvious.

I wish to take this opportunity of expressing my high appreciation to Mr. C. S. Franklin for all the valuable work he has carried out in order to make this system a practical success, and also to Mr. G. A. Mathieu for his practical and theoretical assistance.

I also wish to thank Mr. Ernest T. Fisk, the Managing Director of the Amalgamated Wireless (Australasia) Ltd., Mr. H. H. Beverage, Research Engineer of the Radio Corporation of America, Mr. J. H. Thompson, Chief Engineer of the Marconi Wireless Telegraph Company of Canada, Ltd., Commander J. Lloyd Hirst, Marconi's Wireless Telegraph Company Ltd.'s Representative on the Commercial International Committee in the Argentine and Mr. P. Eisler, Manager of the Cric Construction Co., Ltd., contractors for the High Power Stations of the Commercial Radio International Committee in Brazil, for their most valuable co-operation in arranging at very short notice to successfully receive in their respective countries the signals transmitted from Poldhu.

DISCUSSION.

Admiral of the Fleet Sir Henry Jackson, G.C.B., K.C.V.O., F.R.S., said that Senator Marconi had given some notable, and he might say historic lectures in that room on the subject of wireless telegraphy, but few which could equal that which he had given that day. It was not that the subject-matter was all new; people had been working on 100-metre waves for some time, but he did not think they had ever anticipated getting the results which Senator Marconi had obtained by his systematic study of them in the last few years. It was difficult to follow a paper when one did not know the contents beforehand, so he would not attempt to go into details. He would read the paper with very great interest when it was published. He thought it went far to show that the Austin-Cohen formula would have to be carefully reconsidered. It was evident from what the lecturer had said that another factor had to be brought into account, namely, the sun's altitude—and that factor had apparently a great effect on the short waves. He had not been quite able to catch what Senator Marconi had said about the long route and the short route to Sydney, but it was very interesting to know that there was a long and a short way. The Marconi Company had very courteously helped him a few years ago when he was considering wireless telephony on the Radio Research Board. The Company had given the result of their experience of short waves, and Mr. Franklin himself had explained to the Board his views, but he did not know whether he had then expected to get such results as had been set forth in the lecture. Senator Marconi's work would bring the distant parts of the Empire into closer touch with each other. The technical part, of course, required very deep study indeed. It was very evident that the short-length waves had come to stay, and would be of very great commercial value. One of the things which had struck him most in the short wave length was the speed of working, so that the signals could be recorded automatically. One would never have thought that the strength would have been great enough at very long distances. He heartily congratulated Senator Marconi and his assistants on the very marvellous piece of work which they had just accomplished.

Professor J. A. Fleming, F.R.S., said that he had only seen the paper just before the lecture began, and he felt some diffidence therefore in commenting on it. On those rare occasions on which Senator Marconi spoke in public he always described some epoch-making researches, in which he stood head and shoulders above everybody else. It was very interesting to note that in these researches he had described, the great advance he had achieved had been made by moving in an exactly opposite direction to that of all previous research. He well remembered, although it was now a quarter of a century ago, Senator Marconi's first address to the Institution of Electrical Engineers in 1898 or 1899, when he described his cross-Channel experiments, and showed his early experiments, with little copper mirrors, and described the tests he had made over a distance of about 1½ miles. But at that time the public and scientific interest was concentrated on achieving greater and greater distances, and it was very soon found that for this longer wave lengths were necessary, and therefore Senator Marconi and others went on increasing year by year the wave-length, until, in the last and latest big stations, it was something like ten miles. But having advanced as far as seemed practicable in that direction, he had turned round and gone in the opposite direction, and come down to wave-lengths even smaller than those used in the first cross-Channel experiments, with the result that he had been able to show a very remarkable and interesting advance. There was no knowing whether the limit had yet been reached of the important qualities of the short waves. Until a little time ago there had been a great gap between the shortest wireless waves and the longest dark-heat waves, which was about one-third of a millimetre, but two American scientists had lately succeeded in filling up that gap and making wireless waves of less than a third of a millimetre wave-length, and in the same way at the other end of the spectrum experiments had given shorter and shorter wave-lengths; so that now we were acquainted with a spectrum of nearly 50 octaves of electro-magnetic waves; and it was interesting to know that the researches which Senator Marconi had described were made about the middle of that gigantic spectrum. The great importance of the researches seemed to be not merely in limiting the direction of the waves, but in greatly limiting the power. The figures which Senator Marconi had shown on the diagram before them were eloquent to every wireless engineer of the enormous importance of limiting the power required. It was becoming a very great question at the present time as to how many more high power wireless stations the ether could accommodate. It was becoming rather fully loaded up, even now, and there was probably not an unlimited possibility of putting up stations in the world without making such a disturbance in the ether that nobody would be able to do anything. Senator Marconi's researches seemed to have, in addition to the importance of limiting the direction of the waves and limiting the power, the great value of making more room in the ether; and if that was the case it might become a very little desired thing to put up more all-round stations; and, in fact, the General Post Office might soon prevent it, and no one would think of putting up big stations radiating all over the world in order to communicate with a given point. The Trinity House lighthouse engineer would not think of putting up a gigantic light illuminating all round merely to illuminate a particular channel and guide ships in a particular direction. That seemed to him to be one of the directions in which these new researches would open out a fresh field of work, in that they afforded a still greater, and almost unlimited, possibility of putting up wireless stations.

Mr. C. S. **Franklin** said he had worked with and for Senator Marconi on the subject of short waves for some eight years, first of all in Italy, then at Carnarvon, then at Portsmouth, then again at Carnarvon, and after that at Inchkeith, Hendon, Birmingham, and finally Poldhu. He had published, in 1922, a paper before the Institution of Electrical Engineers which described some of the results which had been obtained. At that time with regard to knowledge which had been collected by himself and by other investigators there was no indication that waves of the order described would be capable of giving useful commercial ranges such as to Australia or to South America, and the results obtained by Senator Marconi on his trip on the "Elettra," in the early part of last year, certainly marked a real discovery which was not known before. The subject of directional wireless telegraphy and reflectors was one which had fascinated him for some years, and he was only going to say that he was very glad to have played some useful part in Senator Marconi's work.

Mr. E. H. **Shaughnessy**, O.B.E. (General Post Office), said the paper was a very fascinating one, and full of interesting experimental results. Perhaps the point that had struck him most was the fact that the very short waves, when transmitted from Poldhu, did not vary and fade during any period at all, but were regular and constant. Of course, quite a lot of experimental work was being done on the reception of short-wave wireless by amateurs, and even by the British Broadcasting Company; recently there had been a display of reception on about 100 metres from Pittsburg, relayed in this country. In that particular instance the fading had been most marked, and he thought the power used by the station K.D.K.A. was of the same order as the power at Poldhu—somewhere between 15 and 20 k.w. on about 100 metres. The day ranges obtained by the short waves did not seem to him anything striking for the power that was put into the set. They were certainly striking as ranges for short waves, but for the power put into the set he thought the various companies which supplied ships with continuous wave installations of about 1½ or 3 k.w. would claim that their ships could work certainly over 1,200 miles day and night; they generally grumbled if their ships did not work to the Devizes station over 1,200 miles.

Another interesting point that struck him was that most of the experiments, those to Montreal and to Sydney, were done without reflectors; so that one had an ordinary station working on 100 metres and working with something like 18 k.w. input, which was able to give a world-wide range—just an ordinary short-wave set. Anyone who had not to deal with wireless matters might not appreciate how much had had to be done to get an efficient transmitter of such a power on such a wave length, and to design an aerial which would efficiently take that power and radiate that wave-length.

Senator Marconi had said that somewhere at Gibraltar, or even at Cape Verde, reducing the power at Poldhu to some insignificant figure—much less than the 9 k.w.—the signals were still as strong as ever. That was what he had understood, and if that was so it was interesting to note that despite the calculations made by Mr. Mathieu, the power at Poldhu was increased from 9 k.w. to some figure about 18, and Senator Marconi was even contemplating a 50 k.w. station. That, he thought, was quite wise, and he was quite sure that Senator Marconi and his very able assistants would not rest content with having at their disposal what they had at present. It was an experience that wireless had shown that under certain limited experiments, carried over a limited length of time, one could not conclude that the results would always be the same. He thought the earliest experiment cross the Atlantic on long-wave was done with something like 3 k.w. Then Poldhu was built, and then from that one got on to much larger stations. It might be that such large stations would never be wanted for the short-wave services; but he thought it was wise to consider the development of as full a power as one could get, even up to 50 k.w.

It had been suggested that the short-wave stations would eliminate all high-power stations, and that all radio-engineers and power people would be out of work. He was not satisfied that that was so. One was very definitely told that these stations had a limited number of hours over which they could work; they would, therefore, not be able at any moment of the day to deal with traffic, and one of the essentials of a good telegraph system was to get rid of the messages as soon as they were handed in. There was, of course, a very large commercial field for deferred work, and obviously a system which cost a small amount to erect, and which would carry a very much larger load per day, could deal efficiently and economically with such a traffic.

Mr. Frank Gill said Senator Marconi had set a very high example in the way he had persevered along a very difficult line, and had apparently reached very fine results. It seemed to him that that was an example to every worker. Professor Fleming, he thought, had hit on an essential point. The advantages to be gained were not so much the saving in power, good as that might be, but the possibility of utilising more stations, because undoubtedly there was a difficulty in the ether being overcrowded. Another reason why too much attention should not be attached to the question of power was that if one guaranteed—and it was a question of guaranteeing—to send a light along, say, a mile distance, in signalling on many days of the year, a candle would be enough; but if one had always to send that light signal through the air, or whatever it might be, then one had to encounter fogs, and because of that changed condition the power must be increased. One could not always work with as small a power as one could on many days of the year.

Captain P. P. Eckersley said he had not seen the paper before he arrived, nor had he intended to speak, but he had heard Mr. Shaughnessy mention the British Broadcasting Company's broadcasts of the K.D.K.A. station, so he immediately decided to rise in defence of his organisation, which had probably broadcast more x's than any other organisation in the world. It was not for him to deal fully with the very illuminating address which Senator Marconi had delivered, nor with the extraordinary field that the short wave working opened up, but there was one point in which he was interested, and that point was the question of telephony. He wanted to get clear telephony, and the transatlantic broadcasts showed that certain distortions were continuously present. His company had continually asked the Americans to institute and put in an independent drive at their end, as they believed this would cure distortion. Apparently they had not done so, and he thought it would be of interest to everyone to know the particular measures adopted by Senator Marconi in order to obtain the pure telephony at night without distortion.

Looking to the future, there was no doubt of the value of short wave working; at present its application to broadcasting was not obvious.

Mr. B. Binyon said there were only two points which he desired to mention. One was that Senator Marconi had quoted the efficiency of the radiation aerial to be of the order of 80 per cent., and in the figure which had been given the over-all efficiency of the whole system was also shown to be about 75 per cent. He thought that indicated some extraordinary progress in the design of valve plant, to have such very small losses in the valves and adjacent circuits themselves. The other point which especially interested him was the fact that Senator Marconi attributed the rapid fluctuations in signal strength on the yacht at the Cape Verde Islands to fluctuations in the wave length itself, and said that had the wave lengths been more constant those very quick fluctuations would probably not have occurred. Of course, every broadcast listener knew the rapid fading effects on the wave length, which was not so very far out from the wave length which Senator Marconi was using; and he wondered whether those quick fluctuations were entirely attributable to small wave-length changes throwing the receiver out of tune with the transmitter, or were due to rapid attenuation effects of the wave itself. Perhaps the author would give some more information on that point.

Dr. J. Robinson said that the paper which had been read that afternoon was a milestone in the history of wireless. He quite agreed with some of the speakers that very often the best way to make progress was to go backwards. Senator Marconi had done that, as had already been pointed out, by going from very long wave lengths right down to 100 metres. Work on longer wave lengths in directional wireless had led to the conclusion that what are called variations of bearings were to be explained by attributing them to the Heaviside layer. Certain doubts had now arisen as to whether there is any Heaviside layer, and attempts are being made by French engineers to determine experimentally whether there is such a layer; but it seemed to him that Senator Marconi's experiments confirmed its existence, owing to the fact that he got by night tremendous signal strength, and by day very small signal strength. In that connexion he wished to ask one question: What was the relative signal strength by night and day? If it took, say, 28 k.w. to communicate with Australia by night, what power would one require by day, and was it impossible to get through? Was the case of a searchlight in a fog and on a clear night a parallel case, or were the conditions such that one could get through by day by putting up the power of the wireless transmitter?

H. E. THE ITALIAN AMBASSADOR said that Senator Marconi had again made a most valuable contribution to the scientific knowledge of the world. Italy was proud to claim him as her son, but he had contributed so greatly to the culture and civilisation of the world that he must be regarded as the son of humanity.

THE CHAIRMAN said he had been immensely impressed with the possibilities of the new development which Senator Marconi had brought to light, and judging by what the other speakers had said that was a meeting of great importance, which would be regarded in the future as a landmark in wireless telegraphy.

SENATOR MARCONI, in reply, said Sir Henry Jackson had referred to some doubts he had had in regard to the waves going east or west to Australia. The waves did not like sunlight; they preferred to travel over a track which was in darkness. In the early morning the darkness extended over the Atlantic Ocean and the Pacific, and the reverse was the case in the evening. Therefore, the waves chose the track which happened to be the darkest. He was very glad Sir Henry Jackson was present, because his early work in wireless should not be forgotten. Although, for particular reasons, it was never published, he thought the Admiral was using short waves during his early experiments.

He wished to thank Professor Fleming very much for the kind things he had said, and to point out that it was very largely due to his invention of the thermionic valve and his researches on the original valves and the rectifying valves that it had been possible to invent the new transmitting valves which allowed the production of continuous oscillations and of short waves.

With regard to what Mr. Shaughnessy had said, he quite understood his question in regard to signal variations or fading. Those signal variations, as he had said, did take place, but over the distances to which he had been referring the variations were not so serious as to make it impossible to receive efficiently, even when signals were at their weakest. He had referred to the results obtained from the American station at Pittsburg. If he was not mistaken the transmission from Pittsburg was telephony, not telegraphy, and if Mr. Shaughnessy had been present at the tests which he (the speaker) had been carrying out, he would have found out that it was very much easier to get an efficient reception telegraphically than telephonically. Distortion affected telephony more than it affected telegraphy. Most of his results, except the radio telephony experiments with Australia, had been with radio telegraphy. He also wished to point out that when reflectors were employed at the transmitting end, the variations or fadings seemed to get much less than without a reflector. He was not quite certain why it was so, but the variations were less. Mr. Franklin had also noticed the same thing over shorter distances. He did not know the reason, but he thought there would be a much smaller variation of signals when reflectors were used. Perhaps in the future, when Mr. Shaughnessy was convinced, as he hoped to be able to prove, that the system was efficient, the day might come when the Post Office might make it compulsory, as Dr. Fleming had suggested; and then one would not be able to work anything else. The instances he had given were for reliable communication which could be obtained any day. On ships it was true that often 1,000 miles could be covered with the existing systems by day, but, as he was a great deal at sea—in the literal sense, his experience was that it was not very certain. He did not contemplate using more than 20 or 25 k.w. at any of the stations, although he thought it was as well to see that they could use 50 k.w. if necessary.

He thanked Mr. Gill for his remarks, and Captain Eckersley had also referred to fading. What he had said in reply to Mr. Shaughnessy would, he thought, answer Captain Eckersley. With telephony one noticed distortion or fading or the signals going off, or whatever it was, very much more than in telegraphy. In speaking to Australia it was not noticed much. It might be that the independent drive introduced by Mr. Franklin at that station, or some particular conditions in Australia, which he did not know of, made the reception fairly reliable.

In answer to Mr. Binyon, who had referred to the efficiency of radiation as being 80 per cent. and the radiation being very efficient, Senator Marconi said he had not made actual measurements himself but he took the figures given by Mr. Franklin subject to confirmation. If those figures were what Mr. Franklin believed them to be it was a very efficient station indeed, and it represented a very marked improvement in the design of wireless transmitters.

With regard to Dr. Robinson's remarks as to the variation of bearings, he really did not know to what extent the bearings of the received signals varied at distant stations. He had only been trying to ascertain the reliability of reception, and he did not know if the direction varied much or not; he thought it did not, but that had to be tested. In regard to the Heaviside layer, there was perhaps no Heaviside layer. He did not want it, especially if it shifted its position every time! With regard to the relative strength by night and by day, the signals by night were certainly enormously stronger than by day, and the indications were that in the middle of the day any practicable amount of power would not get through very long distances. He did not know, however, if by narrowing the beam or by the employment of other wave lengths it might not be possible to do great distances by day. At present, if there was a considerable distance of the track to be traversed by the waves under sunlight, especially if the sun was high, one could not get the waves through. He did not know, however, anything about that, except that it would appear to be very difficult indeed, if not impossible. to get messages to Australia by daytime so far as he had tried. He could not speak in regard to what might be achieved in the near future, when reflectors at both ends are in use.

In conclusion he wished to thank the Council of the Royal Society of Arts for the opportunity given to him of delivering his lecture, and Mr. Campbell Swinton for presiding, and for the remarks he had made in regard to his work; he wished to thank his audience also for their presence, and for the very kind way in which they had received him.

NOTES ON BOOKS.

Masters of Science and Invention. By Floyd L. Darrow. London: Chapman and Hall, Ltd. 10*s.* 6*d.* net.

Architects are apt to complain that the works, if not the names, of the great architects of the past are unknown to the general; doctors make a similar complaint about the masters of their craft; while men of science lament the world's apathy about the famous thinkers who have built up our knowledge of chemistry, physics and other great sciences. No doubt such ignorance is deplorable, and is partly due to the nature of our education, which has hitherto been inclined to stress the literary side at the expense of other branches of study. In the book before us Mr. Darrow has attempted to do something to cure the world's ignorance in respect of the masters of science and invention. He has given us short biographies of a great number of scientific thinkers from Galileo to Marconi, written in such language as to be intelligible to the merest layman, and outlining in a general way the trend of their discoveries, and showing the parts they played in developing scientific theory and discovering scientific facts. The reader who has assimilated this volume will not only be familiar with such names as Lavoisier, Scheele, Berzelius, Liebig, Mendeléeff and Agassiz, he will also have a very fair idea of the particular work which they carried out and of the difficulties they had to overcome in accomplishing it.

PYRETHRUM FLOWERS IN JAPAN.

Pyrethrum flowers are produced in Japan in the Wakayama and Hiroshima prefectures, by small farmers, who dry the flowers and pack them in straw bags. The growers, however have no knowledge of export business procedure, or of the English language, and consequently it is impossible to deal with them direct. According to a report by the United States Consul at Kobe, the dried flowers are purchased from the farmers by jobbers, who, in turn, sell to the exporters. These exporters inspect, re-dry, and repack the flowers into hard-pressed bales suitable for export, and are the only concerns having the facilities for conducting foreign trade.

The price of pyrethrum flowers in Japan is subject to a considerable amount of manipulation. The growers, jobbers, and exporters combine into guilds, whose only purpose is to maintain prices, and, owing to the short supply of pyrethrum flowers in the world, they have been fairly successful in their endeavours.

The following table gives the quantity and value of exports of this commodity from Japan in 1920-2:—

Years.	Pounds.	Yen.
1920	2,926,598	2,553,695
1921	1,127,687	551,549
1922	3,983,083	3,357,188

THE VERMILION INDUSTRY IN HONG KONG.

One of the oldest and best known of the Hong Kong industries is the manufacture of vermilion, which is used by the Chinese for making varnishes, for colouring candles and paper, and for stamping and writing purposes. The annual output in Hong Kong, says the United States Consul there, is estimated to be about 20,000 cases of 50 catties each (66⅔ pounds), the total value being approximately 1,800,000 Hong Kong dollars. Of the total output of 20,000 cases, about 10 per cent. is for local use, 10 per cent. for exportation to the United States and Europe, and 80 per cent. for exportation to Canton, Fatshan, and the neighbouring districts. The exports to the United States and Europe are small in consequence of the competition of coal-tar dyes, which are much cheaper.

There is only one grade of Chinese vermilion, made of a mixture of mercury and red sulphur in the proportion of 100 to 90; that is, 100 pounds of mercury to 90 pounds of red sulphur. The red sulphur employed is secured from the Provinces of South China.

About 20,000 flasks of mercury are annually used in the vermilion industry in Hong Kong.

The mercury is packed in steel flasks containing 75 pounds each and imported direct from Europe, chiefly from Italy and the United Kingdom. The former country supplies 65 per cent. and the latter 25 per cent., the remainder coming from Spain and Belgium."

JOHORE STRAITS CAUSEWAY.

The causeway across the Straits of Johore, connecting the island of Singapore with the mainland, was opened to goods traffic on September 17, and to passenger traffic on October 1, 1923. The ferry system in use for 14 years has been discontinued.

The Johore State railway was opened to traffic in 1909, and a car ferry service was established between Johore Bahru and Woodlands. Each of the ferry boats carried six goods waggons, and passengers were transferred by launches. When the traffic increased from 11,500 waggons in 1911 to 54,000 in 1917, it was decided that other means would have to be provided for its through movement. Construction of the causeway began in 1919. Its cost will be borne jointly by the Governments of the Federated Malay States, Johore, and the Straits Settlements.

When completed, writes the United States Vice-Consul at Singapore, the causeway will contain over 1,500,000 cubic yards of rubble. It is built in an average water depth of 46 feet at low tide. Its length will be 3,465 feet and its width on top will be 60 feet, carrying two railway tracks and a 26-foot roadway. A lock is provided for the passage of local craft, and a rolling lift bridge carries the railway and roadway across the lock. The moving part of this bridge weighs 570 tons and is operated by electricity.

CO-OPERATIVE SOCIETIES IN CHINA.

Co-operative societies in China are limited almost entirely to students' organisations in some of the larger universities, which are of little consequence in the economic life of the nation. Producers' and consumers' societies are virtually non-existent. Certain quasi-co-operative credit societies, however, are found.

According to the official "Commerce Reports," published by the United States Bureau of Foreign and Domestic Commerce, a foreign missionary in Shantung has organised a credit society, known as the Taipu Co-operative Credit Society, in certain Shantung towns. Each member must pay 10 silver dollars (approximately £1) in cash or by instalments. Loans may be raised from outside, with the society as guarantor. A member may borrow from the society if he can get another member as guarantor.

In seeking to provide protection against future famine in famine areas, the China International Relief Committee has recently drawn up a set of rules for the organisation of rural-credit societies in China. The committee promises to stand behind such societies provided they are carried on according to these rules and are under the supervision of the committee. No society has yet been formed on these lines, but surveys of the needs in different communities are being made.

There is an old Chinese institution resembling a co-operative credit society, which is merely called a "hui" or "society." It may consist of any number of people, usually 10, 20, or 30. Each member agrees to pay a fixed amount every month for so many months and the total amount thus collected is drawn for by lot. The duration of the society depends on the number of its members 10 months for 10 members, 12 months for 12 members, etc. When one member has drawn the money for one month he no longer takes part in the drawing. The member who draws first gets the use of the money in a lump sum without interest. The member who is unlucky enough to draw last gets back his 10 deposits without interest.

GENERAL NOTES.

Sisal Hemp Production in the Empire.—Sisal hemp is chiefly produced in Mexico, where the annual output is about 150,000 tons. More than nine-tenths of this goes to the United States, where it is employed for the manufacture of the binder twine used in harvesting the grain crops of the Western States. It is obvious, therefore, that European buyers must look to countries other than Mexico for adequate supplies of the fibre. A résumé of the present position of sisal hemp cultivation in the British Empire is given in the current issue of the *Bulletin* of the Imperial Institute. African sisal, produced in Tanganyika and Kenya Colony, is of excellent quality and large quantities come to this country. The Bahamas also grow the fibre on a fairly extensive scale, but the whole of their output is taken by the United States. No other country is at present producing large quantities of the fibre, but commercial supplies may be expected in the near future from Ceylon, Nyasaland, Gold Coast, Mauritius and Jamaica. Several other regions are well adapted to the crop and have extensive areas available for cultivation.

Yakutsk Fur Trade.—The approximate number of the various furs accumulated at Harbin during the 1922-23 trapping season, and sold and shipped from Harbin in the summer of 1923 were as follows: Squirrel, 700,000; ermine, 30,000; kolinsky, 2,000; red fox, 4,000; white fox, 20,000; gray fox, 500; silver fox, 30; sable, 400; and hare, 100,000. These furs, writes the United States Consul at Harbin, were for the most part shipped up the Lena River and overland to Irkutsk, thence by train to Moscow, where practically all of them were sold to London buyers.

Journal of the Royal Society of Arts.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICES.

PRESENTATION OF THE SOCIETY'S ALBERT MEDAL TO H.R.H. THE PRINCE OF WALES.

The Council of the Royal Society of Arts attended at St. James's Palace, on July 25th, when Field Marshal H.R.H. the Duke of Connaught, K.G., President of the Society, presented the Society's Albert Medal for 1924 to H.R.H. the Prince of Wales, K.G., "in recognition of services rendered to Arts, Manufactures and Commerce as President of the British Empire Exhibition, and by his visits to the Dominions and India."

The members of the Council present were as follows:—Lord Askwith, K.C.B., K.C., D.C.L., (late Chairman of the Council), Senator G. Marconi, G.C.V.O. (Chairman of the Council), Lord Blyth (Chairman, Dominions and Colonies Section Committee), Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., Sir William Henry Davison, K.B.E., D.L., M.P., Sir Archibald Denny, Bt., LL.D., Mr. Peter MacIntyre Evans, M.A., LL.D., Sir Edward A. Gait, K.C.S.I., C.I.E. (Chairman, Indian Section Committee), Sir Robert A. Hadfield, Bt., D.Sc., F.R.S., Rear-Admiral James de Courcy Hamilton, M.V.O., Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S., Major Sir Humphrey Leggett, D.S.O., R.E., Colonel Sir Henry McMahon, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I., Sir Philip Magnus, Bt., (Chairman, Examinations Committee). Sir George Sutton, Bt., Mr. Carmichael Thomas, Dr. J. A. Voelcker, M.A., Ph.D., and Sir Frank Warner, K.B.E., with Mr. G. K. Menzies, M.A., (Secretary of the Society) and Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

They were introduced by Lord Askwith.

Lieut.-Colonel Sir Malcolm Murray, K.C.V.O., C.B., C.I.E., was in attendance on the Duke of Connaught.

COUNCIL.

A meeting of the Council was held on Monday, July 21st. Present:—

Lord Askwith, K.C.B., K.C., D.C.L., in the chair; Sir Frank Baines, C.V.O., C.B.E., Sir Thomas J. Bennett, C.I.E., Sir William H. Davison, K.B.E., D.L., M.P., Sir Archibald Denny, Bt., LL.D., Sir Edward A. Gait, K.C.S.I., C.I.E., Major Sir Humphrey Leggett, D.S.O., R.E., Sir Charles C. McLeod, Sir Philip Magnus, Bt., Senator Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., Sir George Sutton, Bt., Mr. Carmichael Thomas, Sir Frank Warner, K.B.E., and Sir Philip Watts, K.C.B., LL.D., F.R.S., with Mr. G. K. Menzies, M.A. (Secretary of the Society) and Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

Senator Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., was elected Chairman of the Council for the year 1924-25.

The reports of the judges on the First Annual Competition of Industrial Designs were received.

The various Committees of the Council were re-appointed.

Suggestions for improving the *Journal* were considered and approved, the alterations in type, etc., to come into force in the next volume, which will start in November.

Certain alterations in the syllabuses of the Examinations were approved.

The arrangements for Lectures and Papers in 1924-25 were further considered.

Other formal business was transacted.

DOMINIONS AND COLONIES SECTION.

THURSDAY, JULY 24th, 1924; HON. W. ORMSBY-GORE, M.P., in the chair.

A paper on "Recent Developments in the Belgian Congo" was read by M. LOUIS FRANCK, G.C.V.O., Minister of the Belgian Colonies, 1918-24.

The paper and discussion will be published in a subsequent number of the *Journal.*

COMPETITION OF INDUSTRIAL DESIGNS.

The Exhibition of selected works submitted at the Society's Annual Competition of Industrial Designs is now being held, by the courtesy of the Director, in the North Court of the Victoria and Albert Museum, South Kensington, S.W., and will remain open until Saturday, August 30th. The designs exhibited are divided into the following classes: Textiles, Furniture, Book Production, Pottery and Glass, and Miscellaneous. The Exhibition is open to the public free daily from 10 a.m. to 5 p.m., and on Thursdays and Saturdays from 10 a.m. to 9 p.m.

The Reports of the Judges, including the awards of prizes, have now been received, and it is hoped to publish them in the *Journal* at an early date.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

TUESDAY, MAY 27TH, 1924.

DR. J. W. EVANS, C.B.E., D.Sc., F.R.S., President of the Geological Society, in the chair.

THE CHAIRMAN, in introducing the lecturer, Prof. C. Gilbert Cullis, said there had been great interest evinced in the economic wealth of Cyprus for the last 5,000 or 6,000 years; he believed it had been a topic of conversation among those interested in metallurgy in Egypt thousands of years ago. At any rate a great deal of the copper from Cyprus had found its way to Egypt. The mines had also been worked in Greek and Roman times. In the last 40 or 50 years Austrians and Frenchmen had reported on the mineral wealth of Cyprus. When the island became a British Dominion it had been up to us to ascertain exactly what its mineral wealth was, and he was very proud that he had had the honour of recommending for that purpose Prof. Cullis and his brilliant young assistant, Mr. Edge. That his choice had been justified he thought the audience would agree after they had heard the paper.

The paper read was:—

A SKETCH OF THE GEOLOGY AND MINERAL RESOURCES OF CYPRUS.

By C. GILBERT CULLIS, D.Sc., M.I.M.M.

(Professor of Economic Mineralogy, Royal School of Mines, London).

Cyprus first came under British administration—if we except its occupation for a brief period in 1191 by Richard Cœur-de-Lion—in 1878; but on the terms then negotiated by Lord Beaconsfield it remained Ottoman territory and its inhabitants Ottoman subjects. The entry of the Turks into the War, on the side of the Central Empires, resulted in the annulment of that agreement, and since November 5th, 1914, the island has been a British Crown Colony.

The acquisition of this new dependency carries with it new responsibilities, and, in order that the well-being of its people may be promoted, a knowledge of the island's potentialities has become more than ever desirable. It is with the object of calling attention to its mineral possibilities that this sketch has been prepared.

In 1921 the writer was commissioned by H.M. Colonial Office to report upon the cupriferous deposits of the island, and he and his colleague, Mr. A. Broughton Edge, carried out the necessary field investigation in the autumn of that year. The indications of copper mineralisation are widely distributed, and practically all of them were inspected. A unique opportunity was thus afforded of exploring the island and of acquiring a first-hand acquaintance with its general geology and mineral resources.

The examination was necessarily incomplete, however, and it should be understood that, except as regards the copper deposits, the sketch is largely based upon the work of earlier observers, notably Gaudry, Unger and Kotschy, Russell, Bergeat, Reid, and Bellamy. The geological map by Bellamy and the paper by that author and Jukes-Browne were specially helpful, and it is desired to make full acknowledgment of the information obtained from these and other publications.

The geology and economic minerals of Cyprus are remarkably varied. Both sedimentary and igneous rocks are present, the former occupying about four-fifths of the island, the latter one-fifth. The sedimentary rocks range from Cretaceous to Recent; the igneous are generally supposed to belong to one period, viz., Miocene. Assuming this to be so the stratigraphical succession is as follows:—

Pleistocene
Pliocene
Igneous Rocks
Idalian Series (mainly Miocene)
Kythrean Series (mainly Oligocene)
Trypanian Series (Eocene and Cretaceous).

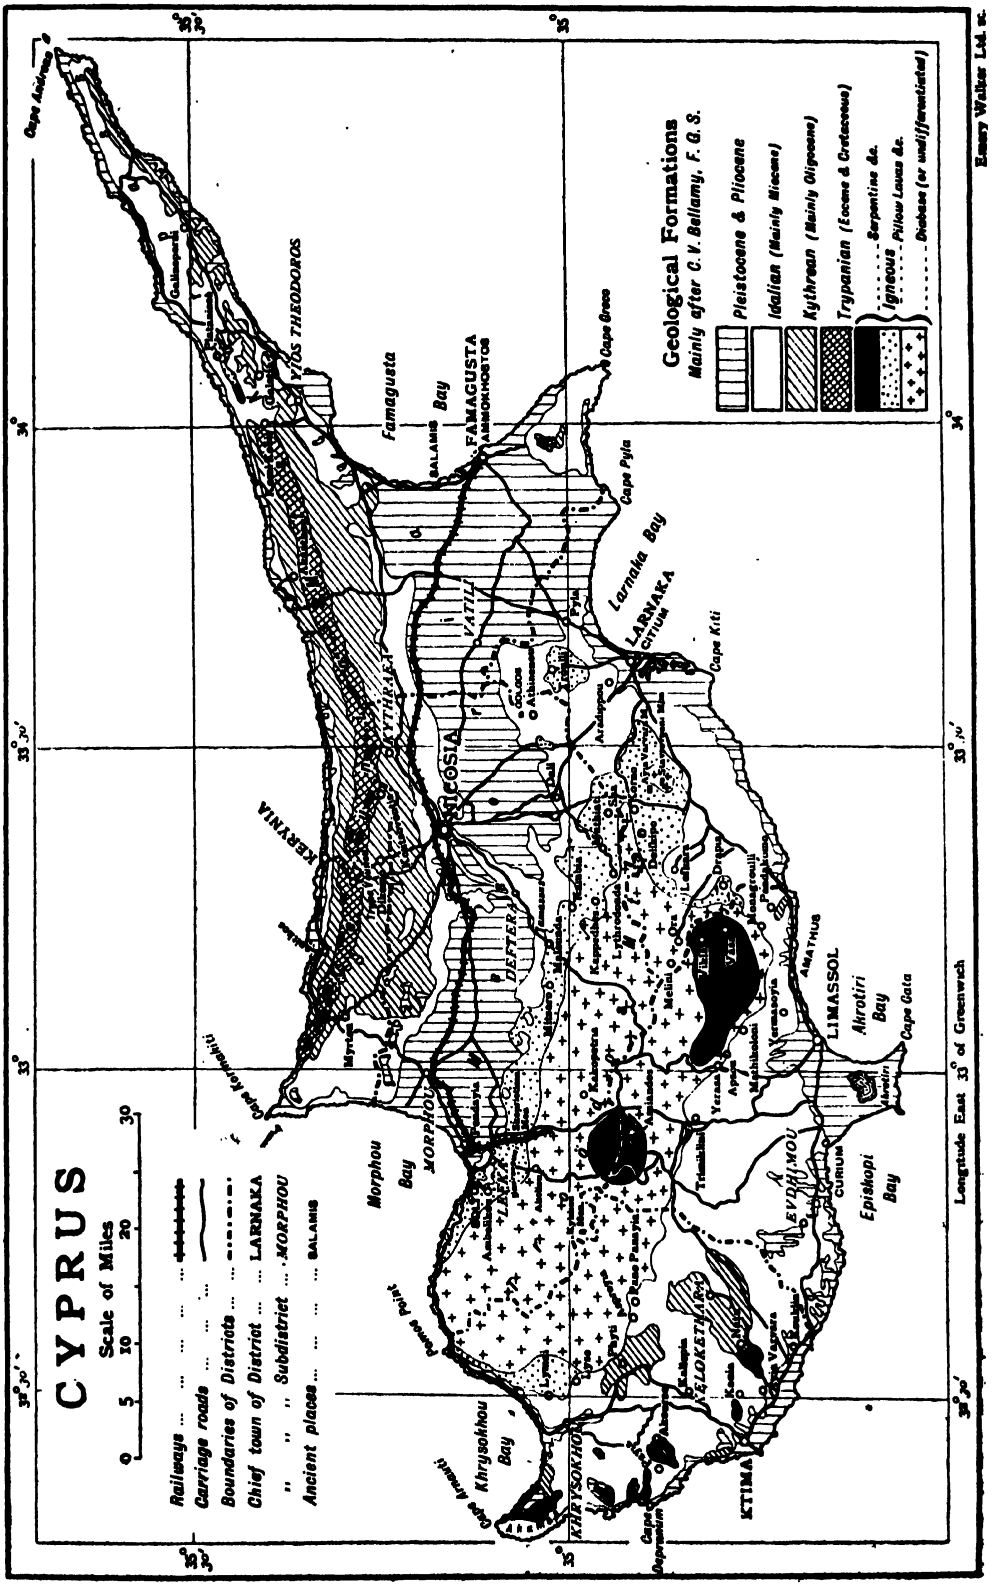

FIG. 1.—Geological Map of Cyprus.

These several groups will be considered in turn, the rocks and general geology of each being dealt with first, the materials of economic interest afterwards.

TRYPANIAN SERIES.

GEOLOGY.

The oldest sedimentary rocks are those forming the ridge of the Kyrenia Mountains. They consist of massive limestones and dolomites. Numerous igneous intrusions are present in them, and by the heat of these, as also by compression, the limestones have been largely changed into marble.

Their outcrop forms a narrow band, nearly 60 miles long, but not more than three across, running parallel with and close to the coast. To the west it ends on the shore near Cape Kormakiti. Its eastern termination is at the base of the Karpass Peninsula. The middle line of the outcrop is marked by a chain of peaks, often over 3,000 feet in height, and the slopes down to the sea and to the central plain, or Mesoria, are very steep (Fig. 2).

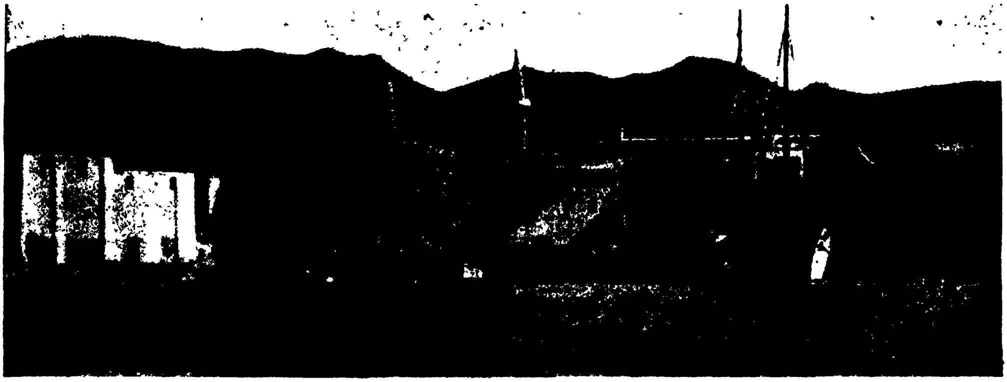

FIG. 2.—Kyrenia Harbour; Kyrenia Mountains in background.

The beds are folded into a sharp anticline the limbs of which plunge beneath the newer strata to north and south. Eastwards the anticline pitches under the later rocks of the Karpass. The folding has probably been accompanied by faulting and these dual disturbances make the determination of thickness uncertain. It has been estimated at 5,000 to 6,000 feet.

No identifiable fossils have been found in these strata. Their age is, therefore, unknown; but from analogy with fossiliferous rocks on the mainland, and especially with the Hippuritic Limestone of Greece, they are generally regarded as Cretaceous.

Limestones of a similar kind, and probably referable to the same series, occur at a few localities in the south-west of the island, where they appear as inliers exposed by the erosion of overlying formations. These small outcrops may indicate the summit of a buried anticline south of the Troödos Mountains corresponding with the Kyrenia anticline north of them. In this southern area, again, the limestones have been invaded and altered by igneous intrusions.

At the western end of the Kyrenia Mountains thin-bedded shaly limestones flank the Trypanian beds on both sides of the range. These are known as the Lapithos Beds and have not been recognised in other parts of the island. Certain foraminiferal shells have been found in them from which an Eocene age has been inferred. Their relations to adjacent formations are difficult to make out. Bergeat thought them discordant with the massive limestones, but Bellamy and Jukes-Browne have reported them to be in conformable relationship and to denote an unbroken Cretaceous-Eocene sequence. On the map (Fig. 1) they are included with the Trypanian.

MINERAL DEPOSITS.

Marble.—The Trypanian is principally notable for its ornamental marbles. They are specially developed where the limestones have been crushed and recrystallised, or intruded by igneous rocks. White, coloured, veined, and brecciated marbles are represented, and along the 60 miles of the range the available quantities must be very large. Bellamy states that some years ago specimens of the best types were sent to Naples to be polished and were submitted to marble experts, who reported them to be of excellent quality.

They are not quarried at present, but appear to have been worked extensively in early times. In many of the ancient and mediæval buildings marbles have been used, practically all of which can be matched in place. Gaudry thought these stones did not originate in Cyprus, but the existence of identical material *in situ*, and the improbability that heavy building material would be imported to a land so well provided by nature, favour the view that the stones employed were of native origin. The possibility of establishing a marble industry in Cyprus might well be considered by those interested in the development of its resources.

Lime and Clay.—The limestones burn to an excellent lime and are quarried for this purpose at several places. The best lime is said to be obtained in the neighbourhood of Dikomo, at Kazaphani near Kyrenia, and just outside Kythrea. The series also yields a plastic clay which occurs in pockets and fissures in the rocks, and is probably a residual material left as the limestones have been dissolved at the surface. In the villages it is used for roof construction, a thick layer being spread over the foundation of brushwood with which the flat-topped houses are thatched.

Petroleum.—Among the limestones a black variety has been recorded which becomes white when heated. Gaudry considered the colour due to bitumen. It is probably the occurrence of material of this kind that has given rise to the belief that petroleum exists in the Kyrenia range, and has led to a certain amount of prospecting for oil. One of the districts where these supposed seepages have been reported is that of Akanthou, and some years before the war Dr. Arthur Wade made an examination of the ground. No developments ensued, however, and it is assumed that the evidence obtained was not considered favourable.

Licenses have at various times been issued to oil-mining firms, some of good standing, for exploration in the island, and investigations have been made, but as no serious work seems ever to have been begun, and permits have been allowed to lapse, it is inferred that no indications of the existence of petroleum or petroliferous rocks on an economic scale have yet been found.

KYTHREAN SERIES.

GEOLOGY.

Succeeding the Trypanian is the Kythrean formation, a series, perhaps 1,500 feet thick, of buff-coloured gritty sandstones and sandy shales, with breccias and conglomerates below and grey-green marls above. The basal rocks contain fragments from the underlying Lapithos beds and Trypanian limestones, indicating an unconformable junction and a break of some importance. The green marls, on the other hand, pass conformably up into the overlying formation.

This series is best developed near the Kyrenia Mountains which it flanks on either side. The northern outcrop is narrow, but the southern is much broader and, indeed, provides the finest exposure of these beds in the island. Beyond the eastern end of the Trynanian ridge the two outcrops merge and continue as a single band, beneath a broken cover of newer rocks, along the whole length of the Karpass.

Besides its principal development north of the Mesoria the Kythrean has a subordinate development south of the Troödos range, especially in the Paphos District. Here it occurs as inliers, sometimes with Trypanian cores. Of these the largest occur in the vicinity of Kelokethara, around Phyti, between Peyia and Akoursou, and north of Neokhorion in the Akamas Peninsula. There is also a small inlier at Pendakomo in the Limassol District. In this southern region the Kythrean beds are often associated with igneous rocks.

No fossils except a few Foraminifera have been found in the Kythrean rocks so that their age has not been determined on a palæontological basis. They are conformably overlain, however, by beds which are definitely Miocene, and cover unconformably others which are Cretaceous or Eocene, and on this evidence are taken to be of Upper Eocene or of Oligocene age. This conclusion is supported by a comparison with similar strata of known date in neighbouring parts of Europe.

MINERAL DEPOSITS.

The Kythrean strata contain little of economic value. Certain of the sandstones are suitable for building-stone, but they are not much used because better material occurs among the limestones of the newer formations. Slabs of some size suitable

FIG. 3.—Well bedded chalks and chalky marls of Idalian Series near Yerasa.

for paving stones, etc., may be obtained in certain places where the sandstones are well bedded and are not folded.

IDALIAN SERIES.

GEOLOGY.

Resting on the Kythrean is a conspicuous formation made up of three members the combined outcrop of which occupies nearly half the island. The included strata constitute the Idalian Series. The middle member, 1,200 to 1,500 feet thick, consists of snow-white well-bedded chalks and chalk marls with layers of flint and chert. These pass down into grey or green marls, about 400 feet thick, containing important deposits of gypsum. The marls are supposed to shade conformably into the Kythrean series below. Above, the chalks are succeeded by rough cream-coloured shelly and coralline limestones.

This triple sheet may once have covered the whole island. Though extensively eroded it still has a wide distribution wrapping round both mountain ranges. Its principal outcrop lies south of the Troödos range and sweeps across from Akamas to Larnaca. It is also strongly developed in the Mesoria, but here it is much hidden by later deposits. From the Mesoria it stretches along the Karpass and thence swings back as a narrow band between the Kyrenia range and the coast.

Over large areas these beds have a flat or nearly flat lie (Fig. 3). This is especially the case in the great southern outcrop and in the district of Dali. Around the Kyrenia hills steep dips prevail and are an expression of the severe folding this part of the island has undergone. All round the Troödos Mountains, too, the strata are highly inclined or contorted. This has generally been regarded as a consequence of igneous intrusion, but alternatively may be due to crushing of the soft sediments against a resistant igneous buttress.

Fossils, though not numerous, are sufficent to prove the beds to be mainly Miocene. They can be correlated with similar Miocene rocks in Syria. The basal gypsiferous marls may perhaps be Oligocene, and if so would be better included with the Kythrean. In like manner some of the highest shelly limestones may possibly be Pliocene. But the central white chalk, the most abundant and characteristic sedimentary formation in Cyprus, is certainly Miocene.

MINERAL DEPOSITS.

Gypsum.—Of all the sedimentary formations the Idalian are the most important from an economic point of view. The most valuable product is gypsum. This is found as crystallised selenite, as massive rock-gypsum and alabaster, and also in a peculiar laminated condition. Its distribution, co-extensive with that of the basal marls, is very wide, workable deposits occurring in all the administrative Districts.

Aradippou and Pyla (Larnaca), Yermasoyia (Limassol), Patriki and Galinoporni (Famagusta), Hagia Paraskevi, Yerolakko and Lefka (Nicosia), Myrtou (Kyrenia), and Letymbou and Kallepia (Paphos) are notable localities. There are others where gypsum is either obtained on a small scale, or is known to occur in workable quantities. Only those deposits which are most favourably circumstanced are at present exploited.

The mineral is quarried. It is exported in the raw state, and is also burnt to plaster of Paris, *e.g.*, at Larnaca and Limassol, the finished product being shipped abroad or absorbed in the island. The quantities and value of the exports for a number of years are given below.

Exports of Cyprus Gypsum.

Year.	Long Tons	Gold (Currency)
1915	2,635	£1,575
1916	3,147	£1,814
1917	490	£319
1918	452	£581
1919	2,970	£5,222
1920	7,114	£10,451
1921	8,881	£9,827

Some of the alabaster, *e.g.*, that from Pyla, is suitable for decorative purposes, and a certain amount has been so used in some of the larger Cyprus buildings. It should also be well adapted to the modern utilisation for electric light shades.

The laminated mineral is extensively quarried, under the name of "marmaras," for interior paving slabs. It cleaves into plates of various thicknesses, which can be sawn to any size or shape and dressed to a smooth surface. It makes an admirable material for floors, stairs, shelves, sills, etc., and is widely used throughout the island in houses and public buildings of all classes. Indeed, it is so serviceable for indoor constructional work that, if better known, a demand for it outside Cyprus might arise.

Umber.—Where the Idalian marls are in contact with the igneous rocks, especially the volcanics, they often assume a dark brown colour and acquire value as the pigment "terra umbra." The umber zone may be as much as 10 or 15 feet thick. The material is soft and earthy, and is usually of a rich coffee-brown colour, although lighter and darker shades occur. Powdered it makes a pigment which in tint and covering power ranks among the best natural umbers known.

The total length of outcrop of the Idalian-igneous contact approximates to 150 miles. Whether the umbers are developed along the whole of this is not known, but the length of contact that is certainly umber-bearing is very great, and the available supplies must be practically inexhaustible.

The umber is of particularly fine quality in the volcanic inlier of Troulli, and it is from this area that most of the present supplies are obtained. The shipping port is Larnaca. Bellamy refers also to production near Limassol. The location of quarries in these two districts has been determined by considerations of transport; equally good material occurs at other places, which might become centres of production if the need arose.

The mining is of a most primitive kind, and seems both inefficient and wasteful. A pit is sunk above the igneous-sedimentary contact, which, after the umber has been extracted to a shallow depth, is abandoned and another opened near-by. The work is done by small groups of Cypriotes who, having no adequate appliances, are unable to follow the mineral to depth. They operate on a contract which covers the mining of the mineral and its delivery to the concessionaire or his agent at port. Some of the mineral is calcined to "burnt umber," but most of it is shipped as "raw umber." It goes principally to Italy and the United States. In 1917 the amount exported was 1,881 tons, valued at £3,746. Cyprus umber, in view of its excellence and the low cost at which it can be produced, should be much more in demand. If given greater publicity it should find a much wider market.

The umbers seem to be modified marls, the modification consisting in their impregnation with iron and manganese. Away from the contact they pass insensibly into snow-white chalks. By many they have been considered to be due to contact-metamorphism brought about by igneous intrusion. This is possible, but there is evidence that they often, perhaps only, occur in association with lavas. This seems to preclude ordinary contact-action, and it is probable that they have been formed by the passage of iron and manganese solutions from these igneous rocks into the later-deposited chalky sediments.

Manganese.—The umber is sometimes of a very dark colour, almost black. This is due to oxide of manganese which occurs as sooty films on the fracture planes of the rock, or as nodules and spongy masses embedded in the matrix. These may be seen at many places. They are well shown in the rich umbers of Apsou, near the Amyrou Monastery.

When in place the manganese is distributed in relatively small amount through the body of the umber, but at outcrop, where the rock has been exposed to long-continued erosion, the nodules are concentrated on the surface or in the soil. In such cases large areas are covered with the ore, which most commonly appears as scattered pellets resembling the droppings of sheep or goats. These are often seen along the junction of the marls and volcanics, *e.g.*, on the eastern slopes of Phoucassa Hill, near the Skouriotissa Mine, and near Aradiou, south-west of Deftera. Considerable quantities can be quickly collected from the ground, and the mineral, as proved by an analysis of material from the former locality which showed 52.18 per cent. of manganese, is of good grade.

Another locality where manganese ore of similar origin occurs is about two miles west of Platanisso in the Karpass. Here irregular spongy masses, consisting of pyrolusite and psilomelane, rest upon volcanic rocks. The latter rocks form an inlier surrounded by Idalian marls, and presumably erosion of the umbers has left the residual manganese upon the surface of the underlying eruptive.

Unfortunately these showings have not been found on a scale promising commercial possibilities, but they prove that manganese occurs in the island, a fact that should not be overlooked by prospectors. They are also of interest as accounting for the high manganese content of the old slags that are so abundant in connexion with the once-worked copper deposits. It would appear that the umber, or possibly the manganese collected from it, was used as a flux in these ancient metallurgical operations.

Zinc.—North of Yerasa zinc blende with a little iron and copper pyrites in a mass composed of siderite, dolomite, etc., has been found in close association with gabbro. The carbonate body may represent a patch of Idalian limestone altered by the gabbro; if so the zinc and copper have probably originated from the gabbro also. The occurrence is noteworthy as proving the existence of zinc, and as suggesting that copper mineralisation in the island may be connected with the plutonic intrusions. It is not yet known whether the zinc is present in workable quantities.

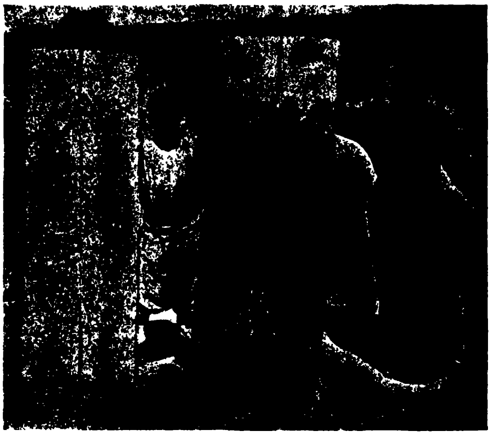

FIG. 4.—Underside of "dhoukani" with trimmed flints in place.

Flint, Lime, "Athienou Stone."—Chalcedonic silica in various forms is abundant in the Idalian. Flints and bedded cherts are plentiful in the chalks; and at contact with igneous rocks silicification has locally taken place, resulting in the formation of jaspers. These siliceous stones are used in making the "dhoukani" or agricultural implement which is universally employed for threshing. (Fig. 4). It consists of a long wide board one end of which is bent up for the attachment of traces. Loaded with one or two seated riders it is dragged by mules or oxen over the threshing-floor on which the reaped corn has been spread (Fig. 5). The flints, suitably trimmed to a sharp edge, are embedded lengthways in rows on the underside of the board and serve to beat out the grain and cut up the straw. Later, by throwing the mixture into the wind, the grain is winnowed from the chopped straw, the latter being used for making sun-dried bricks. This primitive practice has been in use for hundreds, perhaps thousands, of years, and the suggestion has been made that the "dhoukani" may be a survival of the Neolithic age.

Many of the jaspers are of bright colour and might have some value as gem-stones. Probably in the past, when the gem varieties of silica were more prized than now, they were so used, and the traditional fame of Cyprus for its precious stones may to this extent be based upon fact.

The purer limestones, especially the shelly and coral limestones which overlie the

FIG. 5.—" Dhoukani " in use on threshing floor near Lefka.

chalky beds, yield a fair lime, though they are not as suitable for this purpose as the limestones of the Kyrenia range. At several places, notably in the isolated limestone hills east and west of Lefka, *e.g.*, Ambelikou and Koronia, quarries have been opened up for the stone, and kilns, fired with wood-fuel constructed near at hand. These are not in operation continuously but are only used as demand may arise.

East of Dali in the neighbourhood of Athienou the Idalian beds assume a lithological character which gives them special local value. Though continuing soft and earthy they lose their highly stratified structure and snow-white colour, and become thick-bedded, homogeneous, and grey. In this state they yield large blocks of soft freestone which can be cut and dressed in any direction and carved to any shape. This freestone is used for making stone vessels such as troughs, sinks, and bowls for dyeing and washing. The stone stands heat well and is also cut into fire-bricks for grates, stoves, ovens, and furnaces. It is rather deficient in strength and articles made from it tend to be massive and rather clumsy. They are not suitable for export, but being very serviceable are widely used within the island.

IGNEOUS ROCKS.

GEOLOGY.

Igneous rocks play an important part in Cyprus geology. Their principal development is in the Troödos Mountains (Fig. 6). The igneous outcrop here is 50 to 60 miles long by 15 to 20 broad, and has an area of about 1,000 square miles. Besides this main outcrop there are smaller ones to east and west, at Troulli and between Kouklia and Akamas. North of the Mesoria others occur in the Kyrenia Mountains and the Karpass. These scattered masses probably originated from a common source, and it is possible that the whole island is underlain at no great depth by an igneous foundation.

The rocks are remarkably varied. Basic and ultra-basic types largely predominate, but intermediate and even acid types are represented. The bodies are mainly in-

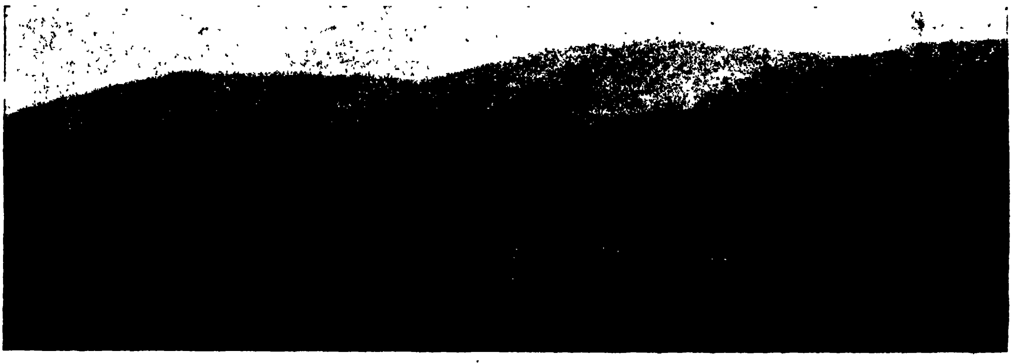

FIG. 6.—View up Evrykhou valley with Troödos Mountains in distance.

trusive, but effusive masses occur on a considerable scale.

Of plutonic rocks gabbros, pyroxenites, peridotites, and serpentines are the commonest; syenite is also recorded from one locality. Among hypabyssal types, diabase predominates, but quartz porphyry and pegmatite occur rarely. The volcanic materials include andesite and basalt, pillow-lavas of andesitic affinities being particularly abundant; trachyte and rhyolite have also been reported. With these lavas volcanic fragmentals in the form of tuffs and breccias are sometimes associated. Of the various rock-types three stand out as of special quantitative importance, *viz.*, diabase, serpentine, and pillow-lavas.

In the map (Fig. 1) the heterogeneity of the igneous areas is expressed by differences of shading, and an attempt is made to suggest the geographical distribution of the three rock-types just specified. The boundaries are rough approximations only, and on a detailed survey would doubtless need substantial modification; but this attempt at differentiation, based as it is upon observation in the field, is thought to be better than a representation of the igneous rocks as of one kind only. Such a differentiation is desirable, because the diabase areas are of little economic significance, while those of serpentine and pillow-lava are of considerable importance.

Diabase.—This rock is confined to the central parts of the Troödos range. Forming the mountain groups of Khorteri-Kykkou, Adelphi-Papoutsa-Machera, and Stavrovouni it constitutes an enormous mass which in bulk greatly exceeds that of any other igneous rock-type (Fig. 7). It is a fine-grained ophitic rock in which the original augite has been changed to hornblende, *i.e.*, it is a uralite-diabase; other secondary minerals, which it contains locally, are chlorite, epidote, zeolites, quartz, and metallic sulphides—a suite suggestive of alteration by hydrothermal solutions.

The limits of the diabase are difficult to discover, and the boundaries between it and associated rocks have never been mapped in detail. In two areas at least it contains intrusive, or differentiated, masses of gabbro, serpentine, etc., and elsewhere, *e.g.*, near Ora and Stavrovouni, it is pierced by small veins of granitic pegmatite. It is surrounded in the foot-hills by a girdle of volcanic rocks, often several miles across. Whether these rocks everywhere intervene between the diabase and sedimentaries is not known. Bergeat states that diabase is never seen in contact with sedimentary formations. Possibly on the map, therefore, the ring of volcanics should be continuous, and not broken as shown. Time did not permit of the whole of this margin being seen, and the volcanics are only inserted where actually observed.

Serpentine, &c.—Serpentine is the most abundant plutonic rock, but it rarely occurs alone. It is usually accompanied by related rocks of the gabbro, pyroxenite, and peridotite families. Some of these latter are remarkably fresh, and are indeed the least altered igneous rocks in the island.

These plutonic complexes occur in isolated masses intrusive into various formations. Thus, in the Troödos range there are at least two masses, one on Troödos itself, and another between Yerasa and Drapia, which are intrusions, or differentiates, in diabase. Between Kouklia and Akamas there are others that have been intruded

FIG. 7.—Kykkou Monastery and surroundings, showing typical scenery of the diabase hills.

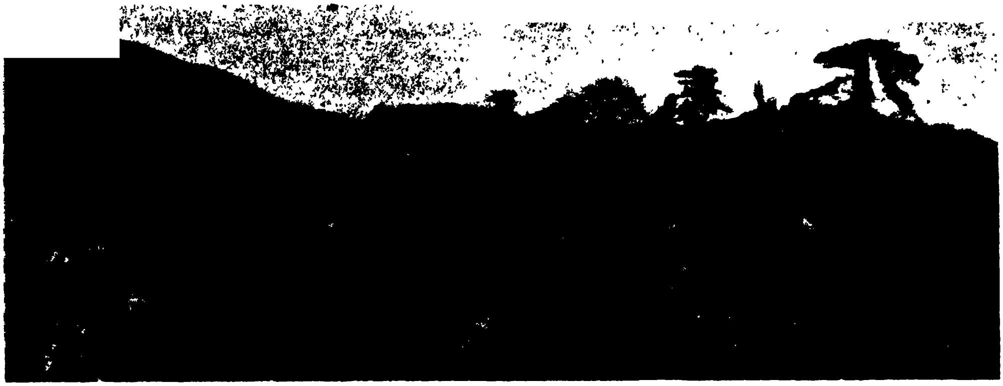

FIG. 8.—Scenery characteristic of the serpentine between Amiandos and Troödos.

into sediments belonging to the Trypanian, Kythrean, and Idalian formations. With some of these occurrences volcanic rocks are associated, and apparently these, too, have been intruded by the plutonics. Similar conditions obtain between Eptakomi and Platanisso in the Karpass. Several plutonic masses are also intrusively enclosed in the Trypanian limestones of the Kyrenia range. Nowhere in the island, however, are Pliocene beds invaded.

There is evidence that the various plutonic rock-types are arranged in zones around a central nucleus, much as in the intrusive bosses of the Urals in which there is a passage outwards from peridotites through pyroxenites to gabbros. The Russian masses are important as yielding platinum, chromite, and asbestos, these economic minerals being confined to the peridotites and serpentines, and it is significant that two of these minerals occur in equivalent rocks in Cyprus.

This zonal arrangement is known to hold good in the great circular boss on Troödos. The centre is peridotite changing, or changed, to serpentine, and carrying chromite and asbestos. This core is followed by enstatite peridotite, then by a true pyroxenite of bronzite and diallage, and finally by gabbro, which is in contact on its outer side with the surrounding diabase. These outer zones are barren.

Pillow-lavas.—The volcanic rocks have their chief development along the northern edge of the Troödos massif, where they form a belt of relatively low foot-hills between the

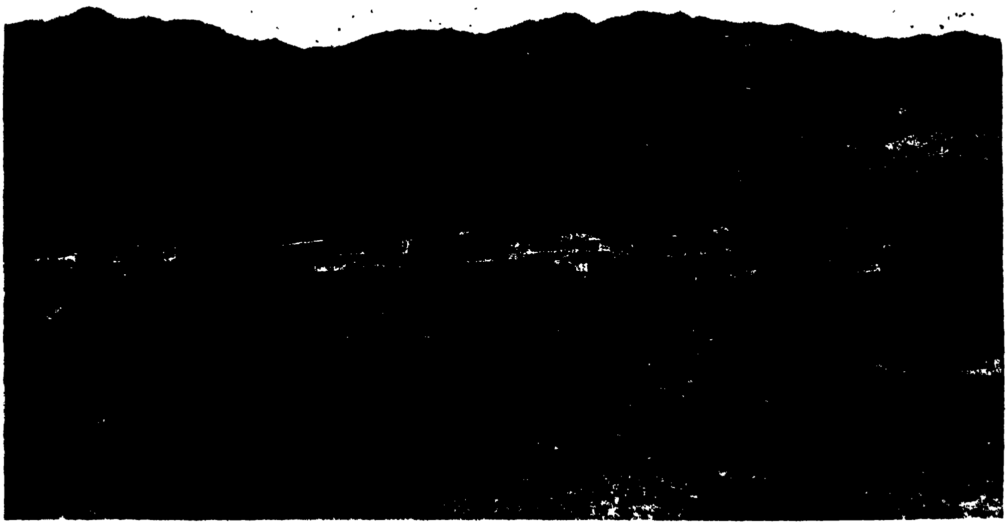

FIG. 9.—Kambia; volcanic rocks covered in foreground by Idalian marls, and succeeded in distance by diabase.

sedimentary rocks of the Mesoria and the diabase of the mountains (Fig. 9). Westward this belt can be traced round the Tillyrian coast to the shores of Khrysokhou Bay and thence inland, past Lymni Mine, to Lyso or beyond. Eastward, it swings by Stavrovouni, which diabase mass it completely surrounds, and returning along the southern margin of the range can be followed to Lefkara and possibly as far as Drapia and Asgata. It reappears between Trimiklini and Perapedhi, and may perhaps extend all along this margin, in which case it would entirely encircle the Troödos Mountains. Rocks of the same kind occur at Troulli, at various points in the south-west, and in the Karpass.

The rocks are mainly andesitic, but basic variants of basaltic type also occur. Many of them are highly scoriaceous, the vesicles generally containing zeolites, &c. These amygdaloids are so abundant as to be a characteristic of Cyprus geology. Another feature they constantly exhibit is a fine pillow-structure (Fig. 10). Glassy chill-margins often surround the pillows, *e.g.*, at Koronia, and in these the vesicles are small; internally the rock has a normal stony look and the steam-holes are much larger. This is distinctive of pillow-lavas elsewhere. Between the pillows marine sedimentary matter occurs, and at one locality, *viz.*, Lymni, radiolarians and sponge spicules have been shown to make up 17 per cent. of this material (see reference 4). The pillow-structure, chill-margins, and presence of marine organisms between the pillows, denote a submarine origin for these lavas. That volcanic action occasionally became sub-aerial is proved by the occurrence of lavas with unmistakable ropy surfaces. These are well seen at Pendakomo. Further evidence of volcanic action is afforded by the occurrence of bedded tuffs, volcanic breccias, etc. Such rocks occur just north of Trimiklini and at other places.

The volcanic rocks, being contemporaneous with the Idalian marls, are of Miocene age, and it is probable that the intrusive rocks associated with them, *viz.*, the diabase and the plutonics, are of the same general age.

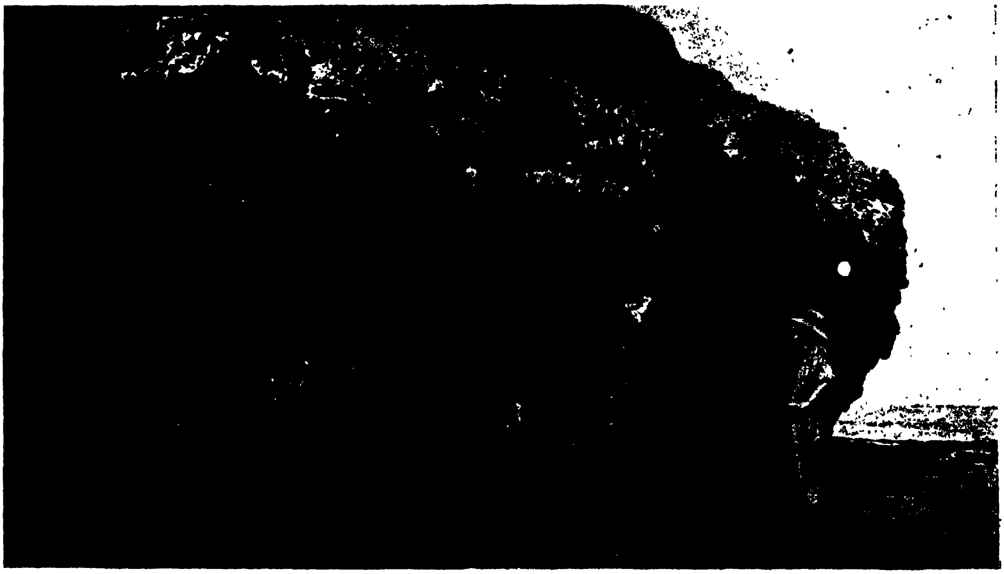

FIG. 10.—Lava with pillow-structure, south shore of Morphou Bay.

MINERAL DEPOSITS.

The igneous formations differ as to their economic minerals. The diabase is the least important in this respect. It has a limited use as road-metal, yields small quantities of clay from which rough pottery, tiles, etc., are made, and here and there is feebly mineralised with copper. The plutonic and volcanic rocks are more important. The serpentines contain asbestos, chromite, and magnesite. The pillow-lavas are the principal depository of the copper-bearing ores. It was from them that copper was won in the past, and it is to them that we must look for such supplies as the island may yield in the future; to-day these ores have an added value for the manufacture of sulphuric acid.

Copper.—From the evidence of old mining operations and ancient slags, the winning of copper was an important industry in Roman, and even in Phœnician, times. Especially large slag heaps are seen at Phoucassa Hill and Mavrovouni near Lefka, and it is here that the ancient mines of Soli are supposed to have been situated. Other large accumulations lie south of Deftera, *e.g.*, at Mitsero and around Lythrodonda, and these are thought to mark the old mining field of Tamassus. Many other localities could be mentioned, and a map showing the places where slags occur would prove how widely the centres of this old industry were spread.

Near the larger slag heaps there are usually surface indications of mineralisation which mark the deposits from which the copper ore was mined. These are in the form of iron-stained patches, which in tints of yellow, red, brown and purple, are conspicuous, even from a distance, and in the brilliant Cyprus sunshine look like oriental carpets laid out on the hill-sides. Since Roman times, and until the late years of last century, no serious interest was taken in these evidences of mineral, and no copper mining was attempted. But about 1880 prospecting was begun, and has been continued intermittently ever since.

The earliest of this modern exploratory work was done at Lymni near Polis in the Paphos District, where there are impressive gossans and abundant signs of ancient mining and smelting. This work has proved the existence of disseminated mineralisation, but no important body of high-grade ore has yet been discovered in the Lymni Mine or concession.

Later, in 1913, the examination of another showy outcrop, on the slopes of Phoucassa Hill, was begun. This lies just above the Skouriotissa Monastery, the name of which refers to the great heaps of Phœnician and Roman scoria which lie at the foot of the hill (Fig. 11). The work was undertaken by an American prospector who had drillers with him, and the ground was systematically tested by boring. Ore was struck in July, 1914. A mining lease was obtained, and the Cyprus Mines Corporation was formed in 1915 to develop the property. The exploration was continued and resulted in the location of an ore-body estimated to contain six million tons of high-grade ore—the first contribution in modern times to the proved copper resources of the island.

FIG. 11.—Ancient slags, Phœnician in foreground, Roman farther back; Phoucassa Hill (Skouriotissa Mine).

The Skouriotissa Mine has been opened up by the above mentioned company to exploit this body. It is within a few miles of the shores of Morphou Bay, with which it is connected by an extension of the Government railway. From the shore near Pendayia a jetty has been built from which the ore can be loaded into lighters for transhipment to vessels lying out in deeper water. Direct connexion with Nicosia and the port of Famagusta is also available by the main line, which passes close to the mine.

Phoucassa Hill, 1,300 feet above the sea, is a sedimentary outlier on volcanic rocks. At the top there is coral limestone, perhaps Idalian but probably Pliocene. This is underlain by typical Idalian chalks and marls. As the igneous contact is neared these pass into umbers. In the mine the umbers rest upon ore, but elsewhere upon the volcanics, which are amygdaloidal lavas with well-marked pillow-structure.

The ore lies between the umber and the pillow-lava, but within the latter. The ore-body is a nearly horizontal slightly concave sheet with an irregular border; in form it may be compared with an oak-leaf with its underside downwards. The length is about 1,500 feet and breadth 750 feet. It is thickest in the middle, about 125 feet, and thins to nothing at the margin. Except along a narrow strip on the hillside, where it outcrops, it lies beneath a sedimentary cover roughly 150 to 250 feet thick. The general level is 800 to 1,000 feet above the sea, and is well above the surrounding country. This facilitates mining.

The ore is cupreous pyrites containing about 50 per cent. sulphur and 2 per cent. copper; it is practically free from arsenic. Much of it is soft and porous and in mining yields a large proportion of fines. The structure is often like that of the volcanic rock, the mass consisting of packed ellipsoids of the same shape and size as the pillows of the lava. This appearance and the finding of residual lava in the cores of the ellipsoids, suggest an origin by replacement. According to this hypothesis, ore-bearing solutions ascending from igneous rocks below were impounded by the impervious marls and, spreading beneath this cover, effected replacement of lava by ore, the pillow-structure of the lava being retained and a porous texture developed as a result of volume reduction. This genetic theory is not accepted by all who have examined the mine. Mr. F. A. W. Thomae, who regards the eruptive as intrusive, believes that the ore is magmatic and essentially a matte injection.

In association with the pyrites mass are smaller bodies of two secondary substances which may prove of value as by-products. These are "devil's mud" and native sulphur. "Devil's mud" is a peculiar material, consisting largely of soluble sulphates, which is found in parts of the mine not far from the outcrop. It contains considerable values in precious metals; a sample gave 2.12 oz. gold and 12.96 oz. silver to the ton. The available quantities are not yet known, but a large body has been proved on the 820 ft. level. At a higher level, *viz.*, the 915 ft., is the "sulphur stope," where a mass of native sulphur has been opened up. Figures supplied gave sulphur 87 per cent., silver 2.02 oz., and gold 0.33 oz. per ton. "Devil's mud" occurs on this level also, in layers between the sulphur and pyrites, and here it is richer than below. Samples showed from 5 to 8 oz. gold and up to 20 oz. silver to the ton. Both of these by-products have originated from the reduction of ferric sulphate to ferrous, and the consequent liberation of sulphur and deposition of precious metals.

The Skouriotissa deposit is the only one so far proved by modern prospecting; but surface signs of mineralisation, at least as marked as at Phoucassa, are known at many other places, and it is possible that important deposits of this type may exist in connexion with some of these. In all cases the showings have the same geological occurrence as at Skouriotissa, *i.e.*, they lie in the pillow-lava at or near its contact with the Idalian marls, and the line of this contact marks the position where the search for additional bodies should be made. Thus, west of Skouriotissa promising indications occur at Mavrovouni and near Akoliou. East of it there are several others, the most impressive being those of Mitsero, Kambia, Kappedhes, Mathiati, Sha, and Delikipo. Along the southern contact evidences of mineralisation are less numerous; those at Lymni are the best known, but others occur at Asproyia, Pano Panayia, Yerasa, and Asgata. Outside the Troödos massif further indications appear in the volcanic inliers of Troulli near Larnaca, and of Platanisso in the Karpass.

Many of these localities yielded ore in ancient times, as is proved by old workings and slags; and within the last few years prospecting permits have been issued for the most promising, and exploratory work is being, or has been, done upon them. If investigations such as led to the discovery of the Skouriotissa mass were carried out, other bodies could hardly fail to be disclosed. Prospectors have not made sufficient use of the facts now known as to the geological occurrence of the ore, or of systematic boring. The only deposit yet proved was located by this latter method and drilling at geologically selected points should be more fully employed.

While massive ore of shipping grade has only been found at Skouriotissa, disseminated ore has been proved at several places, *e.g.*, Lymni, Mavrovouni, Delikipo, etc., and the possibility of mining this and leaching it for copper on the spot, or even, in cases having a favourable topographical lie, of leaching it *in situ*, is worthy of consideration.

Besides these sulphur-copper ores in the pillow-lavas straight copper ores occur, on a small scale, in the diabase. These are mostly found in the mountainous parts of the Troödos range. They have been proved at Kykkou in the west, Stavrovouni in the east, and Melini, Mathikoloni, Monagroulli, etc., in the central region.

At some of these localities no attempt at mining or even exploration has ever been made; at others a little prospecting has been done but in no case with satisfactory results. The mineralisation is in ill-defined shear-zones in the diabase. The principal ore-mineral is chalcopyrite, but at outcrop malachite, azurite, cuprite, native copper, &c., have sometimes been formed by oxidation. The best showing is on Stavrovouni Mountain, a few hundred feet down from the Monastery, where scattered streaks and stringers of copper pyrites are seen in the igneous rock; but the mineralisation is probably too erratic and the position of the prospect near the top of this steep conical mountain too unfavourable for profitable mining. The copper deposits of this class are unpromising, and under existing conditions are of no economic importance.

Iron.—The gossans of the pyritic masses in the pillow-lavas sometimes contain brown iron ore of quite good quality and, in the case of the larger " blows," in fair quantities. Much of it is of a rich yellow or brown colour and possibly could be exploited for ochre if not for iron ore. Small quantities of magnetite and specular hematite also occur in the island, notably on the northern slopes of Stavrovouni about midway between the Stavrovouni and Ayia Varvara Monasteries. Here in the bed of a stream close to the track a considerable body of mixed magnetite and hematite is associated with a pegmatitic rock, both pegmatite and ore being enclosed in diabase. Specular hematite is also said to occur in diabase on a hill called Panayirka, near Monagroulli.

Chromium.—More important are some of the occurrences of chrome iron ore. This mineral appears in the basic plutonics at several places, *e.g.*, on Troödos Mountain, at Troöditissa, up behind Yerasa, at Konia near Ktima, and between Ayia Varvara and Nata. It is a constituent of peridotite or serpentine, and all areas where these rocks occur should be carefully prospected for it. As a rule the mineral is scattered too sparsely through the rock for economic recovery; but it is a notoriously pockety ore, and wherever disseminations occur, exploitable masses may also be found.

Recently, by laborious quarrying and hand dressing, 12 tons of ore were obtained in the Paphos District and sent to England. The places of origin and chromic oxide content are shown below. Most of the ore was good, but the cost of production was prohibitive.

Chrome Ore from Paphos.

Locality.	Cr_2O_3 per cent.
75 bags from Konia	46.02
30 „ „ „	50.39
73 „ Kissonergha	39.04
65 „ Ayia Varvara	54.38

Still more recently, prospecting on the northern slopes of Tröodos has resulted in the discovesy of deposits estimated to contain on the surface, or at very shallow depths, several thousand tons of chromite. A private company with substantial financial backing is now commencing actively to exploit these deposits, and it is hoped that considerable shipments will be made during this season. The accompanying analyses show the quality of the ore. It is probable that other deposits exist in the island.

Chrome Ore from Troödos.
(Dried at 100° C.)

	1	2	3	4	5
Chrome oxide	48.90	51.88	50.80	51.65	49.74
Iron ..	13.47	12.75	12.48	12.36	12.33
Silica ..	4.43	1.93	2.25	2.15	3.26
Magnesia ..	16.79	16.65	16.50	16.95	17.22

The similarity of the peridotites and serpentines which carry the chromite, and of the pyroxenites and gabbros associated with them, to the igneous rocks with chromite, asbestos, and platinum in the Urals, has been mentioned. The rocks of Cyprus are known to contain chromite and asbestos, and the possibility of their being platiniferous naturally arises. While the fact that no platinum has ever been recorded tells against the probability of its occurrence, the geology and paragenesis are peculiarly favourable, and the gravels of streams which flow from serpentine masses might well be tested for this precious metal.

Associated with the serpentine masses of Greece, especially where they are intrusive in the Cretaceous limestones, are the well-known nickel-silicate ores. It is always possible that some of the serpentine intrusions of Cyprus, *e.g.*, those occurring in the Trypanian limestones of the Kyrenia Mountains, might prove on careful examination to be similarly nickeliferous.

The only actively producing field is that of Amiandos, on the eastern slopes of the mountain at an elevation of 5,000 feet. Here surface mining and milling have been proceeding for many years (Fig. 12). In 1907 a concession was granted to the Cyprian Mining Co., Ltd., of Trieste to mine asbestos in the Troödos Forest for ninety-nine years; but in 1919 this concession was cancelled, and a mining lease was granted to a local syndicate. In 1921 property covering six square miles was acquired by the present holders, the Cyprus Asbestos Co., Ltd., by whom it is being worked.

The Amiandos fibre is short and for many years this prevented its utilisation; but with the introduction of uses for short-fibre mineral a demand for it arose, and in normal times it can command a good market. The asbestos-bearing serpentine, though containing only a small percentage of recoverable fibre, is practically unlimited in amount. Prior to acquisition by the present owners the dressing plant was small and not very efficient, and the finished product, packed into 6-foot sacks, had to be transported in mule carts over a winding road for a distance of nearly 40 miles to Limassol for shipment to Europe. An up-to-date installation, designed for an ultimate capacity of 12,000 tons per annum, has now been erected, and an 18-mile aerial ropeway constructed from the mines to the sea near Limassol.

The exports of asbestos from Cyprus,

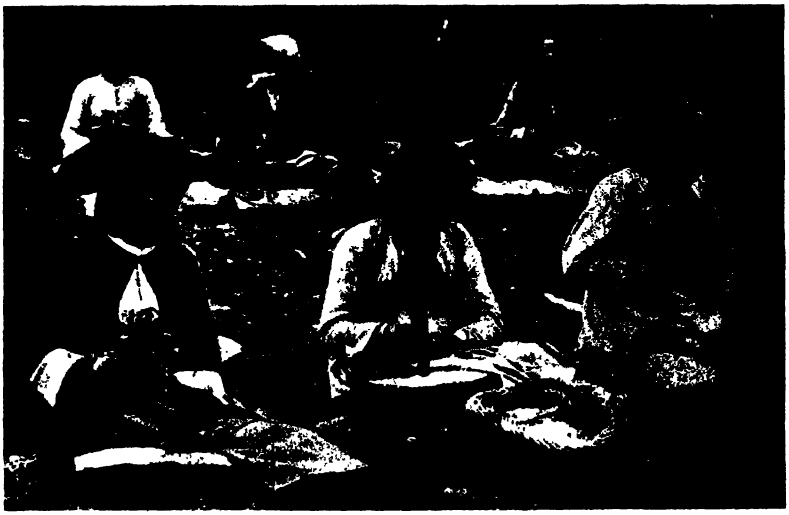

FIG. 12.—Separation of long-fibred asbestos from matrix by hand cobbing, Amiandos-on-Troödos. (Photo. by Foscolo, Cyprus.)

Asbestos.—Asbestos occurs in Cyprus in both its forms, *viz.*, serpentine-asbestos (chrysotile) and amphibole-asbestos. They are found in the basic plutonic rocks, especially the serpentines. The ancients perhaps obtained mineral from these deposits, as they did from those of Italy, for cremation-sheets, lamp-wicks, etc. If so, the longer fibred amphibole-asbestos was probably the variety mined. In modern times only the chrysotile variety has been exploited.

The principal deposits so far located are in the serpentine core of the Troödos boss. In this the asbestos has a wide distribution, being found not only at Amiandos but also in the districts of Kakopetria and Troöditissa, where prospecting licenses have been held by Bell's United Asbestos Co., Ltd., of London, and by various Cypriotes.

wholly from the Amiandos field, are given below for the years 1913 to 1921.

Cyprus Asbestos.
(Exports in long tons)

1913 —	1,168	1918 —	228
1914 —	246	1919 —	1,331
1915 —	1,099	1920 —	896
1916 —	1,291	1921 —	897
1917 —	1,069	1922 —	

Amphibole-asbestos has been found at numerous points. It occurs in the large plutonic boss which lies in the diabase south of Ora, notable localities being Vikla, Vasa, and Apsou; and outside the Troödos range it has been observed in the small plutonic masses of the Paphos District, *e.g.*, near Episkopi. Licenses to prospect for asbestos at these and other places have been issued.

Some of the mineral, *e.g.*, that from Vikla and Vasa, shows fibre six inches and more in length. It is not of spinning quality, however, is liable to be harsh, and is not as uniformly distributed through the rock as the chrysotile-asbestos. Moreover, the technical applications of this variety being restricted, there is little demand for it at remunerative prices. Up to the present no regular mining of it has been attempted.

FIG. 13.—Magnesite prospect (Cyprus Magnesite Ltd.) Akamas Peninsula.

Magnesite.—Besides chromite and asbestos the serpentines contain magnesite. The only place where this mineral is known in quantities having commercial possibilities is in the Akamas Peninsula. Here serpentine is largely developed and in places is covered by limestone. The magnesite is found at or near the contact, and appears to have been formed by the action of carbonated waters from the limestones upon the serpentine.

The best material is high up on the ridge of the promontory, near Kephalovrysia, (Fig. 13) the flat top of the ridge being of limestone, the slopes serpentine. At various points irregular veins and stockworks and concretionary nodules of magnesite are to be seen in the igneous rock, the contents ranging from massive snow-white mineral to mixtures with serpentine in all proportions. An analysis of a sample is given below. It will be seen that the proportion of carbonate of lime in this particular material is rather high.

Cyprus Magnesite from Akamas.

Magnesium carbonate ..	94.00	per cent.
Carbonate of lime ..	4.55	„
Silica and insoluble matter	.98	„
Iron oxide and Alumina..	.18	„
Moisture	.18	„
	99.89	

From excavations which have been made in this district the available quantity of massive and disseminated mineral appears to be large. No regular production had taken place in 1921, but the area merits investigation as a possible new magnesite centre. It is within a few miles of the coast and is well placed for transport by gravity to sea-level.

Recently the principal prospects have been acquired by Cyprus Magnesite, Ltd., of London, and are being vigorously prospected. A road for camel transport has been made to the nearest suitable point on the shore of Khrysokhou Bay, and a line for a projected aerial ropeway has been surveyed. Stocks of mineral are being accumulated both at the prospects and on the coast. Samples properly taken from these stocks, and analysed in Glasgow in March, 1924, show the composition tabulated below.

Akamas Magnesite (Cyprus Magnesite, Ltd.)
(dried at 100°C.)

SiO_2	.14%	.24%	2.38%
Fe_2O_3	tr.	tr.	tr.
Al_2O_3	tr.	.30%	5.58%
CaO	2.73%	3.23%	5.92%
MgO	46.07%	45.10%	37.57%
CO_2	51.41%	51.27%	49.08%
	100.35	100.14	100.53
$MgCO_3$	96.74%	94.71%	78.90%

Alum.—At Lefka and Lefkara the soil is said to be impregnated with impure sulphate of aluminium. It has probably been formed by the action of sulphuric acid, resulting from pyrites oxidation, upon clay. It appears on the surface as an efflorescence after rain and, Bellamy says, is collected and used for washing clothes. From their impurity and limited quantity it is hardly likely that the deposits could have any substantial importance.

"*Terre verte.*"—In certain parts of the island a green chlorite-like substance is found among the volcanic rocks, which has value as a pigment. Its use probably dates back to very early times. It is of a fine blue-green tint, is soft and homogeneous, and grinds to a smooth powder of good permanent colour. From the sub-joined analysis, quoted from Bellamy, it is clear that the mineral is not a true chlorite. The composition is similar to that of glauconite or celadonite; probably it is referable to the latter species.

"Terre Verte," Cyprus.

Silica	52.50
Ferrous oxide	26.44
Potash	15.72
Magnesia	0.84
Moisture	4.50

The chief district for it is that of Malounda, about 15 miles south-west of Nicosia. The volcanic rocks are here cut by columnar-jointed basaltic dykes (Fig. 14). The mineral occurs in steam-holes and cracks in these rocks, and also loose on the ground where it has been set free by weathering

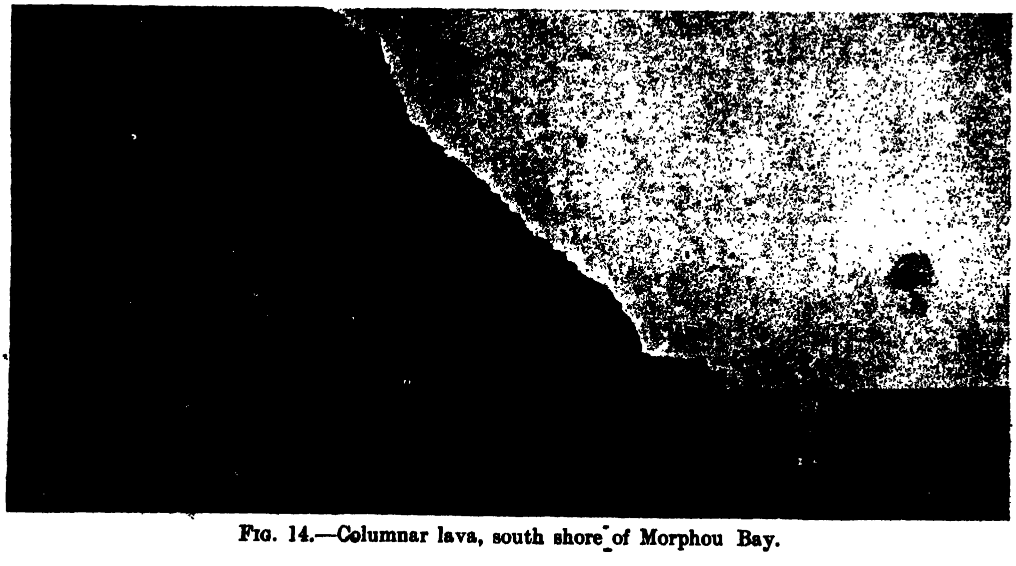

Fig. 14.—Columnar lava, south shore of Morphou Bay.

No definite deposit is developed, and there is no organised mining of the substance. It is collected by the inhabitants and sold to agents in touch with consumers. Some years ago there was a fairly regular export, principally to Italy. Green earth is a mineral pigment for which there seems to be a fair demand, and it is likely that if the existence and quality of the Cyprus material were better known, a more constant market might be created and a more regular output developed. Indeed, in its remarkable deposits of umber, ochre, and "terre verte," the island would appear to possess the raw materials for a useful industry in mineral paints.

Clay.—By weathering the igneous rocks yield residual clays, which are well suited to the manufacture of earthenware, rough pottery, &c. They are principally found on the lower igneous ground, especially in the valley bottoms. Deposits of such material occur at Galata and Phini, north and south respectively of Troödos Mountain, and at Korno, north-west of Stavrovouni Mountain. The two former are on diabase, the last on volcanic rocks. The clays are much used, either on the spot or at works in the larger towns, for making water chatties, wine-and oil-jars—some of very large size—earthenware cups for the primitive water-wheels, roofing tiles, bricks, &c.

Bellamy also records in the southern mountains "extensive deposits of puzzolana" presumably of like origin, which "possesses the virtue of rendering common lime hydraulic."

Road-Metal.—The diabase, if not too decomposed, makes excellent road-metal. Not only is it hard enough to withstand abrasion, but, having a fine felted grain, and containing as it does sufficient chlorite to act as a bond for the harder minerals, it has the additional quality of toughness, which preserves it from crushing under impact. It is used in the construction and maintenance of the well-engineered mountain roads such as those connecting the Troödos camp with Nicosia and Limassol. These are among the best in the island, largely because metalled with this stone. The roads near the large towns, and on the lower ground generally, are rarely so good, the difficulty and cost of obtaining diabase for them, except where certain igneous conglomerates referred to later provide it, leading to the employment of inferior local materials.

The suggestion has been made that the old slags might prove to have some value. They contain both copper and manganese, and it has been thought that one or both of these metals might be profitably recovered from them. A consideration of their composition shows that this is out of the question. But some of them, more particularly the Roman, which are as fresh as when first dumped, would make admirable ballast for railway construction. The material lies loose upon the surface and is already broken: it would therefore be cheap. It is physically strong, packs well, drains dry, and does not encourage the growth of weeds. It is so little affected by sun, rain, and frost as to be practically indestructible. In the south of Spain, where similar slags abound, they have long been used for metalling railway tracks, and with most satisfactory results. If and when a reconstruction or an extension of the Cyprus railway is undertaken, the slags might be of some value in connexion with this work. They should also be of use for ordinary road-making and have been so employed to some extent. But being sharp, brittle, and dusty they are better adapted for foundations than for the actual road surface.

PLIOCENE AND PLEISTOCENE.

GEOLOGY.

The sedimentary rocks of later date than the Idalian belong to two series—Pliocene

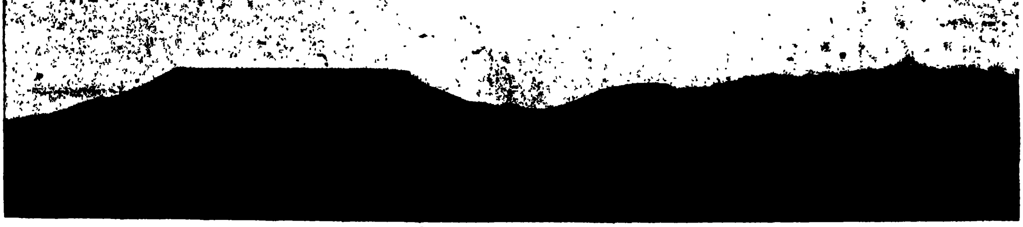

FIG. 15.—Flat-topped hills (Pliocene) of dissected plateau, Mesorian Plain.

FIG. 16.—False-bedded shelly sands (Pliocene or Pleistocene) near Lapathos.

and Pleistocene. They are difficult to separate, largely owing to the fact that the Pleistocene beds have been in the main derived from the erosion of the Pliocene. On the geological map, because of this difficulty, they are indicated as a single formation.

During the Pliocene epoch the present mountain masses formed two islands, and the Pliocene beds occupy areas, in the central plain and around the coast, which were at that time submerged beneath a shallow sea. The rocks are principally shelly limestones and marls, but conglomerates containing pebbles and boulders of the igneous rocks are also common. Such conglomerates are of interest in proving that all the igneous rocks of the island are of pre-Pliocene age.

The Pliocene strata are fossiliferous; foraminiferal, echinoidal, and molluscan remains are abundant. They prove the age and marine origin of the beds and indicate a fauna similar to that of the present Mediterranean. Gaudry inferred from them that two divisions of the Pliocene should be recognised. Later observers have not found reason to question this view.

The Older Pliocene he estimated at about 200 feet thick; it is best developed in the Karpass and appears to pass conformably into the underlying Miocene. The Newer Pliocene, 50 to 150 feet thick, has a wider range; it covers much of the Mesoria, extends to Cape Pyla, and it also occurs in the Akrotiri promontory and along the coastal strip between Kouklia and Ktima. The beds are unconformable to underlying formations.

The Pleistocene deposits include both marine and terrestrial accumulations. They are confined to the present coast-line and to mountain slopes, river courses, limestone caverns, etc. The marine deposits are represented by the materials of raised beaches, coastal terraces, and sand dunes, the terrestrial by surface screes and conglomerates, alluvial sands and gravels, and cave earths.

The rocks consist of loose or slightly consolidated calcareous sandstones or shelly limestones, together with pebble beds, conglomerates, and breccias in which the fragments are of limestone, flint, igneous rock, etc. Travertine and calcareous tufa are abundant, and large smooth surfaces of this veneer are often seen where calcareous waters have issued from limestone hills. The cave-deposits are of special interest because of the peculiar mammalian remains they have yielded to the researches of Forsyth Major and Miss Bate. Pigmy elephant and hippopotamus were discovered, indicating the existence in Cyprus, as in Malta, of a highly specialised fauna of African affinities at no very remote period.

MINERAL DEPOSITS.

The economic materials from these newest rocks are by no means unimportant; they include building-stone, road-metal, and salt.

Building-stone.—The visitor cannot fail to be impressed by the architecture and by the material of many fine buildings in Cyprus. These include temples, castles, palaces, cathedrals, churches, monasteries, and fortifications in various states of preservation, besides modern structures such as bridges and municipal buildings. Many of the edifices are of great antiquity and all testify to the durability of the stone employed.

The finest building-stones in the island occur in these formations; the best coming from the newer Pliocene. They are principally calcareous freestones; but sandstones are also quarried. The rocks are usually of a warm yellow or buff colour, but some are almost as light as our own Portland or Bath stones. Others are darker and range from pale to dark brown; these, besides being less pleasing, are generally softer and less durable.

The quarries are distributed widely, and good stone is procurable in all the Districts. The most productive quarries are those favourably placed as regards the large towns. Thus, excellent sandstone is worked just west of Kyrenia and south-east of Nicosia; and limestones at Ayia Phyla north of Limassol, at a number of points round Famagusta, and at Ktima.

Road-metal.—The igneous pebbles and boulders of the coarse conglomerates serve a useful purpose in providing excellent material for road making. The pebbles are peculiarly hard and tough, only such igneous rocks having survived in the conglomerates as were capable of withstanding exposure and abrasion. Most of them are diabase, but fine and coarse gabbro and other rocks are not uncommon. They have been derived from the igneous complex of the Troödos Mountains. Natural processes have broken down and sorted these rocks, and transported them to distant localities where no other material suitable for road-metal occurs, and it is this circumstance that gives the conglomerates their special value.

The pebbles are collected from the surface or from stream-courses, where the beds have been disintegrated. They are dumped at convenient points along the main roads and are reduced to macadam size either by hand or by a portable crusher driven by an oil engine (Fig. 17).

FIG. 17.—Igneous boulders from conglomerates being broken for road-metal, Nicosia-Troödos road. (Photo. by Foscolo, Cyprus.)

Salt.—The Pleistocene formations have a special interest because it is from basins in them that the inhabitants obtain their supplies of salt. The deposits are formed by the drying up of salt-lakes which lie south-east of Larnaca and Limassol. At both places the lakes occupy depressions in areas of flat low ground which within comparatively recent times were covered by the sea, lagoons having been converted into lakes by the growth of intervening bars of sand.

The Larnaca salt-lake is the more important, and is one of the most interesting natural features in the island. Its shore is irregular and has a circuit of some ten miles, but its area is only about two square miles. The lake is separated from the sea by a low barrier of land only a few feet above the level of the highest tides. The bottom is 10 feet below sea-level. On its landward side it receives streams which flow down from hills of chalky limestone and igneous rock.

The belief among many Cypriotes is that the salts are brought into the lake by the streams, which are supposed to have dissolved them from the soil. But as Gaudry, Unger and Bellamy have shown, in genetic theories differing only in detail, they are derived from the sea. Indeed, to prevent the access of too much fresh water and consequent dilution, with the possibility that the summer heat would not cause solidification, a side channel has been constructed to conduct surplus land waters to the sea.

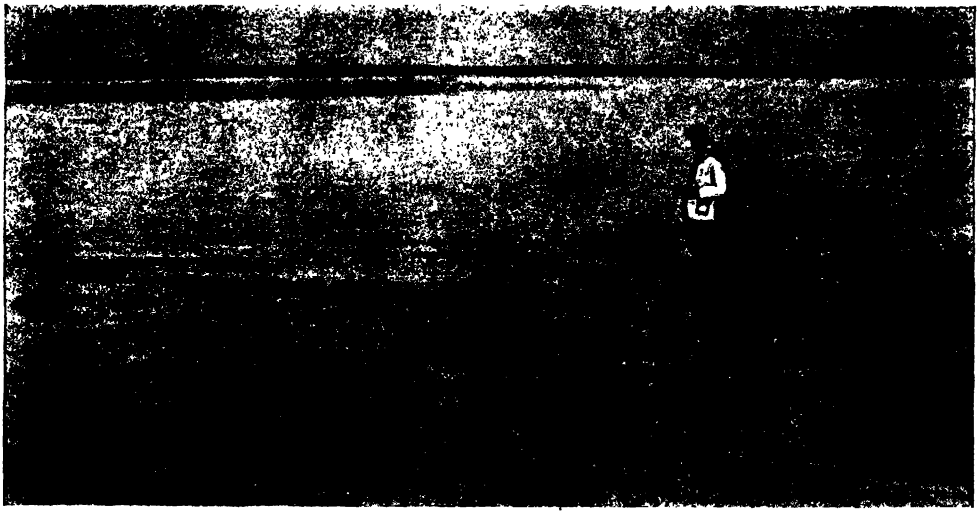

Fig. 18.—Larnaca Salt Lake in summer, showing surface of solid salt and low sand-bar towards sea.

During winter, when evaporation is at a minimum, sea-water percolates through the somewhat porous barrier and fills the lake. As the hot weather comes on, evaporation removes the water faster than percolation can introduce it, and eventually supersaturation and precipitation are brought about. By the end of the summer a cake of salt several inches thick, and on which it is possible to walk as upon ice, covers all but the middle of the lake (Fig. 18). In the following winter inundation again occurs and the supplies are thus regenerative.

The harvest begins in August. The salt is dug some way out, loaded into mule panniers, transported along a temporary causeway, and dumped high and dry on the bank. Some may also be sacked for distribution. The stock piles are built in the form of truncated pyramids, each being marked with the year of origin, and each containing many thousands of tons of salt of excellent quality (Fig. 19). In these the mineral sets and becomes hard and compact so that very little loss results from rain. Supplies are quarried from the piles as required.

Luke and Jardine (1920) give the cost of winning at about 3s. per ton, and state the annual crop to be 3,125 tons (2,500,000 okes of 2.8 lbs.). The salt is Government property and its sale a monopoly. Special guards and inspectors are appointed to watch the lakes and reserves, and to see that there is no illicit salt manufacture. The annual revenue derived is about £9,000.

Most of the mineral is consumed in the island, but there is some export, and if a demand from outside could be encouraged and markets established a very profitable export trade should be capable of development. The exports in 1919, 1920, and 1921 were severally 480, 615, and 885 long tons.

Complete desiccation of the lakes seems never to take place, and a considerable volume of mother-liquors remains. Apparently the composition of these has not been fully investigated. It would be well that the liquors should be analysed, since valuable salts of other metals than sodium, *e.g.*, potassium or magnesium, might exist in them in quantities worth extracting.

FIG. 19.—Salt stock-piles on shore of Salt Lake, Larnaca.

From what has been written above it will have been gathered that the geology and minerals of Cyprus are both interesting and important. They are, however, very imperfectly known. No systematic geological survey of the island has ever been made; neither have its mineral resources been thoroughly investigated. Moreover, its mining laws are antiquated and out of harmony with those of other parts of the Empire. Now that Cyprus is a Crown Colony it is highly desirable that work in these directions should be officially undertaken; and, in conclusion, the opinion is expressed that a new branch of the public service, having the functions and discharging the duties of a Geological Survey and Department of Mines, might with great advantage be added to the existing administrative machinery of the island.

DISCUSSION.

THE CHAIRMAN (Dr. J. W. Evans) was sure the author of the paper had succeeded in imparting to the audience some of the enthusiasm which he had for Cyprus and all things appertaining to it, and he thought many present would now feel an interest in both its capabilities in the future and in its long and interesting past. Personally he should feel inclined to put back its metallurgical past rather longer than Prof. Cullis did. It was generally believed that our word "copper" came from Cyprus, because that was the original source of the metal. In Egypt copper had come into use before 3,000 B.C., and where should the Egyptians have got it from if it was not Cyprus? He would humbly submit that the Phœnicians had started to work at that date and had exported their metalliferous products to Egypt. The whole subject of past references to Cyprus was of the greatest possible interest. It would be easy to compile a whole chapter of different references to Cyprus by ancient writers. Theophrastus, the authority on minerals, stated that some of the "*kyanos*" used as blue paint came from Cyprus. Another variety was an artificial one made in Egypt out of copper, which no doubt also came from Cyprus. In Cyprus there was a river called the Amiandos, the modern form of *amiantos*, which meant "taintless," and the name was no doubt given to the river, on account of the pureness of its water. From the fact that the early mines of asbestos occurred near the source of that river, one of the ancient names for asbestos was *amiantos*. One could go on for a long time dealing with those ancient references to the mineral wealth of Cyprus. The author had referred to the use of the *dhoukani*,

the curious threshing sledge which had little fragments of flint stuck into the bottom of it. He had seen exactly the same thing in use in Spain, and curiously enough there the little flints were derived, just as they were in Cyprus, from Miocene limestones. There was no doubt at all that that same kind of sledge was used by the Romans. In Spanish it was called a *trillo*, a corruption of the Latin term "tribulum" applied to the same object. When one said that anybody had suffered great tribulations, one was inferring that his troubles were as bad as if he had had that horrible instrument drawn backwards and forwards over him!

He desired to ask the author whether clay was put upon the brushwood on the roofs of the houses in Cyprus in order to prevent fire: if not, what was the object of putting it there?

He had been very interested in the author's suggestions as to a further search for petroleum. The author proposed that the prospector should bore down through the gabbro and other igneous rocks, which might form a sort of roof over the more ancient sedimentary rocks, which might contain petroleum. Of course, it would be merely a sporting chance. There was one obvious criticism, namely, that igneous rocks came up from below, so that one could not expect to bore down through them to sedimentary rocks. He would suggest the answer to that was that it was by no means true that all igneous rocks came immediately from below; they were brought up at some place by earth movements, and then, much more often than not, they flowed sideways. So that a great fold of igneous rocks might have originally flowed in as a thick sheet, and then been raised up by earth movements to form an anticline.

Mr. F. A. W. Thomae, A.R.S.M., M.I.M.M., thought the lecture, delivered at the time of the British Empire Exhibition, was especially opportune, as so little was yet generally known about the latest acquisition to the Empire.

He had been interested in the genesis of pyrites deposits in Cyprus. It would be more accurate to say that he was inclined to believe rather than that he believed those deposits to be magmatic segregations. In the interesting discussion he had had with the author in the pages of the *Mining Magazine*, he had brought forward that theory of magmatic segregation as against replacement, because he thought it had several points which required serious consideration. There were, however, a number of geological questions involved, which very greatly contributed to the issue, and on which still a considerable amount of work was required before a definite pronouncement could be made on them. For instance, there were still questions about the true nature of the eruptive rock, its age, the age of the Idalian sediments, etc. There were also questions of observation, such as a careful study of the ore umber-contact which was now being opened up in mining, and the eruptive sedimentary contact where there was no ore, and other points. So that it would be premature, he thought, to be convinced of the truth of either of those theories before more positive light could be thrown on those questions. So far, the opinions of different authorities who had studied them were by no means unanimous. He would like, however, to point out that as an aid to prospecting those two theories did not conflict. In either case the outer margin of the eruptive was the line of least resistance for the expulsion of the ore, whether as a segregation from the molten magma or as aqueous solution after its solidification. That was where the ore bodies had to be looked for, and a capping of sedimentaries was in either case essential for their preservation.

With regard to the age of the Idalian series, specimens collected by him from the top of Phoucassa Hill and submitted to the Jermyn Street Geological Survey had been reported on as indicating oligocene rather than pliocene age.

Mr. Louis N. Schoenfeld (Managing Director of Cyprus Magnesite, Ltd.), thought the author had not dwelt sufficiently on the mining resources of Cyprus, such as magnesite. A good deal of money had been spent recently in connexion with the production of magnesite and great developments had taken place. If any member of the audience would care to visit the offices of his company he could show them photographs which were quite as interesting as those which had been thrown on the screen that afternoon. He had recently had a letter from a gentleman in Sweden in connexion with his Company's ore in which he stated that the only trouble with regard to it was that it was too good. The development of the asbestos side of Cyprus was also rapidly going ahead, as he could testify from a recent visit to the island.

The Chairman enquired if the difficulty of finding those deposits to which the author had referred could not be solved by the process of electric prospecting.

Prof. Cullis, in reply, said the object of covering the brushwood on the roofs with clay was, he imagined, to keep out rain. In Cyprus the rainfall was in heavy showers rather than in a continuous downpour, and had not a serious effect on soft tenacious clay, especially after it had hardened. As to discovering ore-bodies by electric prospecting, he thought that was quite possible. A better type of ore-body than that found in Cyprus could not be desired for location by electric prospecting, because running into millions of tons concentrated into a small area. Another method which might be attempted was the gravity balance of Eötvos. He considered that Cyprus was a place where that method also might be employed effectively. He hoped that the day would arrive when scientific methods of prospecting would be used to assist the ordinary methods hitherto employed. That was one reason why he thought some official department might with advantage be established in Cyprus, which could foster and develop the mineral industry, do all that was necessary to create new markets for Cyprus minerals, and also encourage more scientific methods of prospecting.

He was obliged to Mr. Thomae for the remarks he had made. He had intended to discuss the origin of the cupreous pyrites deposits, but he had been overweighted with material and had not had time to do so. He agreed with Mr. Thomae that enough was not yet known to enable one to be dogmatic. Mr Thomae's theory was an ingenious one, and might possibly hold, but his own hypothesis, namely, that the deposits had been formed by local replacement of the pillow-lavas, had a great deal to commend it, and he was inclined to adhere to it for the time being; he had, however, an open mind in the matter.

He had been interested in Mr. Schoenfelds' remarks. He could have dealt more fully with magnesite, but had had no time to do so. He did not know that the magnesite properties had been so much developed since he was there in 1921. When in the island he was much impressed by the magnesite occurrences. He had seen hundreds of tons of excellent magnesite collected on the surface waiting to find a buyer. The quality was also good, and he had not been able to understand why it was that the mineral could not be marketed. The magnesite deposits in Cyprus should be capable of important developments in the future.

He desired to take the present opportunity of expressing his thanks to Dr. Evans for having nominated him to go to Cyprus for the Colonial Office to report on its cupriferous deposits. It had proved a most interesting trip. He would also like to congratulate Dr. Evans on having done the same thing for other British Colonies. Dr. Evans had long been an adviser to the Colonial Office on the geological and mining possibilities of the Crown Colonies, and had sent investigators to several of those Colonies, with, he believed, very good results.

He concluded by thanking one of his colleagues, Mr. Grantham, for kind assistance rendered in making many of the lantern slides used in illustration of the lecture.

The Chairman, in proposing a vote of thanks to the reader of the paper, said the reason he had recommended Prof. Cullis for the work had been that he was quite sure he was the right man, and if the Colonial Office had as good work done in other parts of the Empire as they had had done in Cyprus, they would be very well satisfied. There were unthinking people in some of the Colonies who considered that a geological survey was of no value. They were perfectly willing to advocate the spending of money on agriculture, but when it came to geology they said it was merely ornamental and entirely useless. Geologists did not think so, and, as the author had hinted, it had been possible to show recently that geological surveys gave very important results.

NOTES ON BOOKS.

How to Paint Permanent Pictures. By Maximilian Toch. London: Scott, Greenwood and Son; New York: D. Van Nostrand and Co. 7*s.* 6*d.* net.

The cynic who asserts that it is no bad thing that many modern pictures are painted with materials that will perish before the painter—even he will scarcely refrain from regretting the havoc to be seen in most art galleries among works of great importance, caused by fading, darkening or cracking of paints. The subject is one that has troubled many—both painters themselves, collectors, and amateurs of art and general satisfaction was expressed at the announcement made a year or two ago that the Royal Academy had appointed a strong committee to investigate the whole subject. The matter is very complicated, involving the study of various chemical and physical problems hitherto but little explored, and it will probably be some considerable time before a report is issued. In the meantime artists who desire to see their pictures remain in sound condition would do well to study Mr. Toch's volume. It is the work of one who has had over thirty years' experience in the manufacture of pigments for all types of painting, and its object is to convey to the painter in simple langugage the reasons why certain materials should be used and others avoided.

Of the making of pigments there appears to be no end. To quote Mr. Toch: "One German manufacturer of considerable reputation mentions seventy-nine varieties of green; one hundred and twenty-three varieties of yellow; one hundred and seventy-nine of red; seventy-five of brown; seventy-nine of blue; thirty-two of black, and twelve of white. . . . All in all, one German catalologue contains five hundred and seventy nine varieties of colours." While some of these are good sound pigments. others deserve the worst that can be said of them. How is the unfortunate painter to know which is which? We commend Mr. Toch's suggestion that manufacturers of artists' materials should be legally compelled to label every tube of paint as to its permanence and chemical composition; but, until that is brought about, painters will find no surer guarantee against the premature decay of their works than in a careful study of this practical little handbook.

WOOL INDUSTRY OF CZECHO-SLOVAKIA.

The production of sheep's wool in Czecho-slovakia during 1923 is estimated by local authorities at 4,158,000 pounds, writes the United States Acting Commercial Attaché at Prague, a reduction of 145,000 pounds from the previous year. Since the major part of the home-grown wool is used in the home-manufacture of cloth, no accurate figures are available. Those given are based on the estimated number of sheep in the country in 1923. The last animal census in December, 1920, indicated a total of 985,000 sheep. Since that time a decrease amounting to approximately 40,000 is reported, principally in the Provinces of Bohemia and Moravia. The breaking up of the big landed estates has, it is said, made impossible the maintenance of the former large flocks. As a normal shearing yields approximately 2 kilos., or 4.4 pounds, per sheep, the estimated 945,000 sheep in 1923 justify the calculation of 4,158,000 pounds for the 1923 wool crop.

The well-developed wool-manufacturing industry in Czechoslovakia requires annually, under normal conditions of full operation, about 77,000,000 pounds of washed wool. The equipment consists approximately of 450,000 spindles for combed yarns, 596,000 spindles for carded yarns, and 34,450 mechanical looms. The products vary from the coarsest yarns and fabric to the finest.

As the domestic production of wool represents only a small fraction of the normal needs of the industry, and since, as already indicated, the bulk of the domestic wool is used in home manufacture, the country is dependent almost exclusively on foreign markets for its wool supplies.

PERSIAN AMBARI HEMP PRODUCTION.

Persian ambari hemp (*Hibiscus cannabinus*), locally known as Kenaff, before the war was grown to quite an extent in Guilan and Mazanderan, Persia's two richest Caspian Provinces. Russia consumed practically the entire production. The ensuing disorganisation of the Caucasus and Russia's virtual extinction as a market wiped out this industry just as they ended Persia's formerly flourishing Caspian silk-cocoon production. Whereas in 1913-14 Persia exported to Russia 2,408,848 pounds of raw hemp and flax, valued at about £18,000—the customs returns combine the two, but hemp forms by far the larger part—its exports in 1920-21 only reached 19,760 pounds, and in the following year, 213,811 pounds. The entire exportation, both pre-war and at present, represents the raw material, shipments of hemp cord being negligible.

From a report by the United States Consul at Teheran it appears that the Guilan villager is free to plant hemp if he so desires, provided that it does not involve sacrificing the cultivation of his allotted rice fields or mulberry groves. It requires higher and drier land than rice and is commonly planted in the hedgerows. Most villagers raise just enough for their own use, Since the mulberry groves have been allowed to deteriorate, however, following the demoralisation of the silk industry, the villagers are gradually planting more hemp.

Hemp is planted in the spring and matures in the autumn. It is then buried in mud for some days and the fibre stripped off. Persian manufactures of hemp are confined to cord for domestic use. The quality of the fibre is said to be improving, but is still too soft for effective ropes of any size.

GENERAL NOTES.

Arsenic Deposits in Chile.—Several large deposits of arsenic are known to exist in Chile, principally in the Provinces of Atacama and Santiago, but apparently no serious attempt has ever been made to work them. In the opinion of the United States Consul-General at Valparaiso, the owners would undoubtedly be found ready to commence operations if convinced that the output could be sold in the world's markets at what they consider a fair price. There is a large deposit situated in the Andean foothills close to the capital and to rail transportation, and less than 100 miles from tidewater. It is understood that an analysis recently made in the laboratory of the University of Santiago shows an arsenic content of over 90 per cent.

Indian Sandalwood Oil. The two pioneer sandalwood oil refineries working at Bangalore and Mysore City utilised 750 tons of sandalwood cut from Mysore forests during 1923, as against 508 tons in the previous year. Oil sold during this period amounted to 149,630 pounds, as compared with 115,028 pounds in 1922. According to a report by the United States Acting Trade Commissioner at Calcutta, both factories have made such good progress in the manufacture of a special grade of sandal wood oil suitable for the Japanese trade that this oil has now displaced the German product from that market. The prosperity of the industry is due to the efforts of the Mysore Government to exploit the vast forest resources of sandalwood found in the State and to manufacture a high-grade oil suitable for export markets.

Manufacture of Fish Flour in France.—The fish-flour industry, which originated in La Rochelle and is confined entirely to that centre, is of comparatively recent origin. Hitherto, writes the United States Consul at La Rochelle, the non-edible fish that were found in the nets of trawlers were thrown into the sea, but now they are brought to port to furnish material for the fish-flour plant. The one plant now producing fish-flour can handle with its present installation from 8 to 10 metric tons of fish and fish waste per day, which represents an annual production of 450 to about 600 metric tons of fish flour. The product is used in all the agricultural sections of France and is exported to Switzerland, Spain, Italy and Germany. Fish flour has an important alimentary value since it is rich in protein and in phosphates. It is mixed with feed for poultry, rabbits, dogs, sheep, cattle, and hogs. Experiments in feeding fish flour to cows and chickens have demonstrated its value in increasing the production of milk and eggs.

Journal of the Royal Society of Arts.

No. 3,742. VOL. LXXII.

FRIDAY, AUGUST 8, 1924.

8 SEP. 1924

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICES.

INDIAN SECTION.

A meeting of the Indian Section Committee was held on Wednesday, July 30th. Present: Sir Edward A. Gait, K.C.S.I., C.I.E., Ph.D. (Chairman of the Committee) in the chair, Sir Charles H. Armstrong, Sir George C. Buchanan, K.C.I.E., Sir Krishna G. Gupta, K.C.S.I., Sir Claude H. Hill, K.C.S.I., C.I.E., Major-General Beresford Lovett, C.B., C.S.I., Sir John O. Miller, K.C.S.I., Mr. N. C. Sen, O.B.E., Major H. Blake Taylor, C.B.E., and Mr. N. N. Wadia, C.I.E., with Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

COMPETITION OF INDUSTRIAL DESIGNS.

The Exhibition of selected works submitted at the Society's Annual Competition of Industrial Designs is now being held, by the courtesy of the Director, in the North Court of the Victoria and Albert Museum, South Kensington, S.W., and will remain open until Saturday, August 30th. The designs exhibited are divided into the following classes: Textiles, Furniture, Book Production, Pottery and Glass, and Miscellaneous. The Exhibition is open to the public free daily from 10 a.m. to 5 p.m., and on Thursdays and Saturdays from 10 a.m. to 9 p.m.

PROCEEDINGS OF THE SOCIETY.

TWENTY-THIRD ORDINARY MEETING.

WEDNESDAY, MAY 28TH, 1924.

LORD ASKWITH, K.C.B., K.C., D.C.L., Chairman of the Council, in the chair.

THE CHAIRMAN said those present were going to hear a paper entitled "The position of the Arabs in Art and Literature," a great subject, of very wide extent and very difficult to compress within a short compass. The lecturer was a lady whose name had become well known throughout this country, and, he might say, throughout a great many other parts of the world. She was an enterprising traveller, who had been to places very few European travellers had ever visited, and possibly to some where no European traveller had been. She had written books about her travels and adventures, but, more than that, she had studied the history and the art of the peoples among whom she had been. That history and that art varied in different countries where the Arab conquerors had spread themselves, and where they had either adapted the traditions of the country to which they went, or had impressed their views upon it.

He did not wish to anticipate one word of what the lecturer was going to say, but he would introduce her at once, particularly as the Spanish Ambassador, who had favoured the Society with his presence that afternoon, and whose country was highly interested in matters connected with the Arabian movement, had to leave early and would desire to hear as much as he could of the lecture.

The paper read was:—

THE POSITION OF THE ARABS IN ART AND LITERATURE.

By MRS. ARTHUR MCGRATH (Rosita Forbes).

The position of the Arabs in art and literature is an immense subject to be tackled in one paper, especially as such position can only be defined by reviewing what the rise and decline of the Arab races have left us. Arab art alone covers architecture, wood carving, ceramics, miniatures, ivories, carpets, stuffs, arms, bronzes, incrusted metals, gold and silver work, enamelled glass and illuminated MSS., while their literature is one of the richest in the world.

Herodotus, Eratosthenes, Artemidorus, described the marvels of Arab art which existed centuries before Christ at Mareb, the city of the great dam, and it would appear that in the Sabæan and Himyaritic kingdoms the pervading influence was first Indian and then Persian. From pre-Islamic days the gold work of Yemen has been famous throughout Arabia, and, though it is continued to this day, the oldest designs are still the best. The rock city of Petra and other early ruins show traces of Arab art, but much must have been destroyed by the primitive Moslem conquerors, who regarded the representation of figures as idolatrous. With the rise of the Caliphate, art was patronised by the ruling princes, and there was an influx of artists from Persia, Egypt and Syria.

There were no books on art, though ornamental designs were found in works on geometry and architectural drawings in miniatures. Designs were handed down in families and kept secret. Some of the earliest of these were used in carpets and embroideries, and the sculptors of the West reproduced them, as in the mouldings of the doors at Konia and at the Sebil of Kait Bey, near the Al Azhar University. In Cairo there are columns carrying out carpet designs, and in the Tunis museum is preserved woodwork which is a copy of embroidery. The art of the goldsmiths gave the ideas for the mosaics at El Aksa in Jerusalem and Qubbet es Sakhra. Early tiles were copied from Persian stuffs. The first descriptions of art concern the products of weavers and jewellers. Abul Feda, writing of the reception of an ambassador by the Caliph of Bagdad, describes a hall hung with 38,000 pieces of tapestry, of which 12,500 were embroidered with silk; and a golden tree with swaying branches, from which sang all sorts of jewelled birds. The Arabs conquered countries that were always more advanced artistically than they were themselves, so they were of necessity influenced by the taste of the subjugated nations. In Iraq early Arab art was influenced by Sassanian, Chaldean and Persian; in Syria, by Copt, Byzantine and Egyptian; in North Africa, by the neo-Latin art of Spain, Byzantine and a little Greek and Roman. The minarets of Samarra in Iraq show Chaldean influence and the towers of Ibn Tulun, Cairo, are similar to those of Babel, and the Chaldean Ziggurat, observatories. The Chaldean and Assyrian method of baked clay decorations and of beaten sheets of metal exist to-day in Iraq, as in the mosque of Kazimein, near Bagdad, with its tiles of gilt copper.

Parthians, Romans, Persians, Byzantines fought for Syria, which was the bridge between Asia and Africa, and even Yemen was subject first to the Sassanians and then to the Persians up to the time of the Prophet. The so-called Arab arch found at Sidi Okba, Kairawan, Cordova, Jerusalem is seen in the Sassanian monuments of Takht-i-Ghera. Professor Pelliot showed a picture in a recent lecture of the same arch in a Buddhist cave in Chinese Turkestan of a much earlier date. The plaster mouldings which are typical of Arab architecture were originally Sassanian.

After Yemen, it was Iraq which first established itself as a centre of art, and, from Iraq have come, but often by way of other civilisations, the so-called Arab arch, the vaulted roofs, enamelled earthen walls, the metal plates for domes and the decorative mouldings. In the first centuries of the Hegira the Arabs took their decoration, not their architecture, from Byzantium, and it was the artists of Jerusalem, Cordova and Damascus who came from Constantinople. After the Turkish conquest the great Byzantine monuments influenced Arab architecture, while the decoration became Syro-Egyptian. The octagonal Qubbet es Sakhra was one of the earliest Syrian edifices purely Byzantine, but, from Constantinople too, came the carved wooden doors, marble faced walls, bronze laid on wood, carved marble screens and windows, mosaics in all forms. The Khans, of which there exist some exquisite specimens in Damascus, were a Byzantine product, and Byzantium inspired the great military architecture of Palestine during the Crusades, and her cisterns, learned from Rome, are copied all over North Africa. The Byzantine dome replaced the early Sassanian or Mesopotamian, and mosaics the ceramics, as in the mosque of Omar at Jerusalem. The Arabs became very expert in this latter branch of art, and they established it in Spain, where the Cordova mosque is decorated with mosaics of glass. It must be confessed, however, that though possibly the Arabs developed this Art, the Roman ruins in Algeria and Tunisia show the same marble and cut porcelain mosaics (the opus sectile of Rome) as in Cairo, Damacsus and Tlemcen.

Typical of Arab art is the use of geometrical designs, but in Italy, in Roman mosaics, in Baalbek and in Palymra, there are traces of the same designs, and they are found in Sassanian stuffs. It would seem, therefore, that the Arabs perfected a certain style of Eastern architecture and decoration without originating any portion of it.

The early mosques of the Iraq or first Arab school had a square court with a fountain in the middle, surrounded by porticos, the deepest being on the East and holding the mihrab. They owed their beauty to paint and gold leaf, not to their rich materials, as may be seen in Ibn Tulun in Cairo. As the Syrian school replaced that of Iraq, the mosques show precious marbles, metals and enamels. Nur-ed Din built several of this kind in Damascus. In the 13th century there appeared, originally presumably from Iraq, where the four Islamic Codes had birth, later from Syria, the cruciform plan on which so many Cairo medersas are built (typical of the four orthodox rites, Hanbali, Shafei, Maliki, Hanafi).

Under the Fatimite Caliphs a distinct Syrian style developed, and the architects who constructed the three great gates of the Cairo fortifications were Syrian. The Fatimites were Shias and heterodox, so in the decorations of their period one finds human figures and animals, but they disappear again under the Ayyubites. The use of stone, of many coloured marbles, of stalactites, and of scientific instruments came from Syria, and her architects are responsible for some of the finest Arab buildings, while their influence in details persisted even after the Turkish conquest. The Syrian architecture differs from the Byzantine in its abundance of floral decorations, but in Egypt and North Africa ancient columns, brought from Roman and other ruins, are often used in early Syrian mosques. It is rare to find in Egypt columns made by Moslems. Even the architecture of Constantinople is borrowed from the Syro-Egyptian school. Many of its monuments have disappeared, the earliest in the Crusades or the wars of the Mongols and Turks, when Aleppo and Damascus were sacked. Later buildings were destroyed when the Mameluke Sultans tried to re-establish their authority in Syria. Such wars, however, were responsible for the perfection of Syrian fortifications.

Typical of this school are the Moslem charitable foundations, often connected with the tomb of the founder, as at the Moristan of Kalaun in Cairo, where, within one wall, are the tomb, a mosque and a hospital. Other buildings associate with the tomb, fountains, schools and mosques. To the Syrian school are due some particularly fine public baths, and the caravanseries, which were at the same time mosques, schools, hospitals and fountains.

The Turks introduced the many cupolaed mosque, but made no impression on civil architecture. I have seen their mushroom cupolas in the big mosques of Yemen and even in the desert mosque at Aujela on the way to Kufara. Under the Mameluke Sultans the palaces and civil buildings in Syria and Egypt grew richer in decoration, and it is to this period that some of the most exquisite interiors in Damascus and Cairo belong.

During the first centuries after the Hegira Kairawan, the capital of the Aglabites, and Cordova of the Omeiyads were the centres of Western Art. In the 9th and 10th centuries A.D. Morocco was the cradle of a new brilliance, not uninfluenced by the Berbers.

Fez, with its exquisite mosques and colleges, was founded in 807, and Marakesh two hundred years later, but when Spain was conquered by the Sultan of Morocco in the eleventh century she was not impressed by this Moorish art. On the contrary Spanish Arab art, then producing its best, created some remarkable monuments in Morocco. In the 12th and 13th centuries this renaissance of the West spread into Algeria and Tunisia, and reached its climax in the 14th and 15th.

Curiously enough it was not till after the fall of Granada in 1494 that Western Arab architecture took its most definite form. The ancient style can be seen in the fortifications of Granada, Cordova, Seville and Toledo, in their palaces and their mosques. The later typical Western mosque had parallel naves and a wider central nave, with the mihrab as a tower, a square minaret and a great porch richly decorated, and this served as a model for many North African mosques, which were generally built over cisterns, to which water flowed from terraces. The West has no cruciform medersas, as the Malekite rite is supreme. Its medersas are simpler and contain rooms for students. Its zawias are like large Arab houses, sometimes adjoining the tomb of the founder, as at Jarabub in Lybia. The fortified zawias (such as Sousse) were colleges and fortresses belonging to the religious military orders, which, under the Almoravide Sultans, had so much power. The fortifications of the West are among the most interesting in the Arab world, especially those of Sfax, Sousse, Fez, Meknes, Tlemcen—with their massive square towers and double walls, sometimes crenelated, the towers alternating on the two walls.

After the 16th century Western Arab art declined under European influence. Many Algerian mosques were built after the plan of churches, and both the architecture and the faïence were copies of the Spanish and Italian.

General Lyautey in Morocco has done much to encourage the revival of Arab architecture; and Raisuli's great palace at Azeila is an excellent example of modern Arab work, but the Mediterranean countries have much to forget in the way of European tawdriness before they can go back to their old art. In Xauen, a little time-forgotten town in Spanish Morocco, there are some beautiful, fairly modern houses built after the old style with the two tiered galleries supported on double arcades, round a central court, but the most interesting modern purely Arab domestic architecture I have seen is in North Yemen and Asir, where the late Emir Mohamed el Idrisi, himself no mean architect, encouraged the merchants to build large well-proportioned houses after his own model at Sabya; and in Jedda, where mason and wood-carver go out together to the selected site and plan the rooms on the spot, the wood-carver receiving 20 per cent. more than the mason because his work is more precarious. From Mr. St. John Philby's careful descriptions, the great palace of Ibn Sa'ud, at Riadh, must be a fine example of modern desert architecture, but this has changed little with the centuries, since its style is regulated by the quality of material and labour obtainable on the spot. Unfortunately, the secret of the peculiar glaze used on the decorative Arab tiles has disappeared. Sayyid Dahan has been experimenting on this for some time in Damascus, and has actually succeeded in reproducing the old bluish green colour in a form of paint. This has been tried on the roof of one of the new public buildings, and, so far, it appears to be identical in effect with the ancient material, which had the quality of always looking fresh.

Arab painting was hampered not only by the stern inhibitions of primitive Islam, but by the recurrent puritanical movements, the last of which is the Wahabi, which were always opposed to any form of art or luxury.

Makrizi mentions mural paintings in the palace of Ibn Tulun, and the Fatimite Caliph, Mostanser Billah and his Vizier, Yazuri, were much interested in illuminated Korans. Ibn el Aziz, of Bussora, painted the former's walls, using red figures against a yellow background; but nothing remains of the work Makrizi describes, nor of that Abu Bekr Mohammed (d. 975) mentioned by Abul Feda. Monsieur Musil, the Czecho-Slovak Arabist, who spent twenty years among the Shammar Arabs, discovered mural paintings at Kosseir Amra in the desert East of Moab, which are supposed to date from the 9th century. In the Alhambra are paintings on leather of hunting scenes and councils, which, by some (notably Gerault de Pranzey) are supposed to be Arab, by others Italian.

Moslem art excelled in illuminated volumes—the name of the painter is often dissimulated in minute characters in the corner of a scroll—but the best were Persian, for the Shias were not hampered by the scruples of the orthodox concerning human and animal figures. There is a great sense of movement in some of the hunting scenes, and a French authority points out that "Certain drawings by their precision of feature and subtlety of line are not unequal to the drawings of Ingres; certain animals not unworthy of Pisanello." Few illuminated missals can be attributed to the devout Arabs of the early centuries of the Hegira, but after the 13th century they made progress in the art. Under the Ayyubite dynasty the first illuminated MSS. lacked imagination. They showed Byzantine influence and saintly halos sometimes crept in by mistake. The most important existing Arab MS. is a copy of the Muqamat of Hariri containing 101 miniatures, executed in Iraq in 1237, and of great value, since it represents historical scenes in the correct clothing.

The Arabs eventually excelled at illuminating Korans, geography and natural history books. An example of the latter is the curious "Marvels of Nature," dated 1283, in which the drawings are fantastic and unreal, but full of imagination. The most exquisite art was expended on a thirteenth century Koran in the British Museum, of which certain pages give the impression of rich silk carpets, but the finest Korans are in the Arab Museum in Cairo.

The same museum shows admirable specimens of wood-carving of the 15th to 17th centuries. In those years the highest art was expended on the mimbars and mihrabs, lattice work for windows, doors and friezes. Syria was rich in hard wood, such as pines and cedars, and probably exported to Egypt. Early examples of the carver's art were found in the tomb of Ain el Sera of the 8th or 9th century. The mosque of Ibn Tulun, in Cairo, has the whole Koran carved into a decorative frieze. The panelling of houses and medersas was particularly fine, though it had to be done in small panels to avoid shrinkage from the sun, and boxes to hold the Koran show a wealth of beautiful detail, getting richer as the years advanced. In the 14th century ivory was used to decorate doors and panels, and these two arts have suffered perhaps less than any others in the decay of Arab power. The woodwork of Syria and the Hedjaz and the decorative designs in ivory, which are so finely done that it looks as if the wood had been embroidered with ivory thread, are still admirable.

There is in the South Kensington Museum a cup of carved ivory made by Mohammed Saleh in Cairo, in 1521, with the inscription "In truth the righteous shall drink from a cup perfumed with camphor," which marks the apex of the Arab ivory work. This art was famous in Spain in the 10th and 11th centuries, and the coffers, goblets, handles, plaques, often decorated with animals and human figures in high relief, show an imagination fertile, ingenious and complex.

In the Bargello, in Florence, there are two ivory plaques from the 14th century Iraq, carved, one with winged griffons, and the other with human figures, among vines. These are among the finest known specimens. The Arabs also worked in cloisonné, enamels, engraved copper, silver and encrusted metal. Exquisite specimens of these arts are preserved in the European and Arab Museums, and the various schools of native art and industry in Spanish and French Morocco, Tunis, Syria, etc., are endeavouring with some skill to reproduce the old designs. Damascus has succeeded to a certain extent with her metal work, and there seems to be a distinct future for this branch of Arab art.

It is a pity that the making of arms has so completely died out. Yemen is still famous for her hilts and scabbards, but she imports the blades. Modern Moorish blades are but a poor copy of the old Spanish Arab work. In the 13th century Cairo was the great market of arms, but in those days it was the quality of the blade which appealed to the Arab; the ornamentation of the hilt was less important. An existing Arab proverb says: "There is only one gift for the brave--a blade." Syrian blades passed on from one generation to another with the addition of different hilts. In the list of gifts sent by Sultan Beibars to the Ilkhan of Persia, Abaga, were arms from Damascus. The sword of Duke Emanuel Philibert of Turin, in the 16th century, had a Damascan blade, but 100 years previously, the Syrian workmanship had passed its zenith, though "Damascan" remained a generic term for finely tempered steel. The Arabs brought the perfected industry to Spain, though it had already existed to a certain extent at Toledo, and it was in Spain that the ornamentation of arms attained its greatest richness about the 16th century. The sword of Boabdil II., last King of Granada, is preserved at Madrid. The blade is from Toledo, the gold hilt enamelled in blue, red and white, with a centre of carved ivory, and it bears a Kufic inscription: "Attain your end (but) in safeguarding your life."

Stuffs of all kinds have formed an important part of Arab art.

Coptic influence shows in the early Egyptian Arabic tissues, but the introduction of animals and figures was due to Persia. Geometrical designs were often interwoven, together with verses of the Koran, or lines in praise of the future owner of the stuff. It is sometimes possible to tell the date by such inscriptions. In 774 Egypt provided the hangings for the Ka-aba at Mecca, and these grew in splendour till Ibn Jubair, visiting Mecca in 1182, describes and admires the richness of the 34 strips of green which covered the whole of the outside, and were themselves covered with woven inscriptions. Makrizi describes a tapestry made for a Fatimite sultan, which represented the earth, with all its known cities, seas, and mountains, rivers and roads, the names woven in gold and silver.

During the middle ages Alexandria was world-famous for her tissues and European merchants came there to buy them. As early as the 8th century chroniclers speak of caravans returning from fairs at Damascus and Aleppo laden with precious stuffs, embroideries, tents, cushions, mattresses and purple silks.

In histories of the Crusades constant mention is made of Damascan brocades.

Marco Polo says that even the beds in the post-houses had curtains of silk, and at Mosul he notes the silk brocaded with gold called "mosulin," the origin of muslin. During the Abbassid Caliphate at Bagdad, portraits of famous people were woven in silks, and in the 14th and 16th centuries the school of Mosul was famous for its tapestried hunting scenes, with lion, hare, gazelle.

Zobeida, wife of Harun al Rashid, is supposed to have founded Kashan, famous for its velvets, brocades, carpets woven with gold, taffetas and cut velvets. These Kashan carpets, since gold was used in them, were probably not the knotted carpets at all. These seem to have originated in Persia, but, under the Ayyubites, fine carpets were made at Emessa in Northern Syria. A 13th century carpet with Arab inscriptions is supposed to have come from the Mohed Din mosque in Damascus. Early carpets are best studied in the old Flemish and Italian pictures, and it is probable that some of the carpets thus portrayed came from Syria and Asia Minor, and were brought from the Mediterranean coast by Venetian mariners. Still, carpet making can never have been a definite Arab art, and I am afraid the recent efforts by hand and loom seem to prove that it never will be. On the other hand, the modern silks interwoven with metal thread of Syria and Morocco are very beautiful, as are some of the embroideries.

It may be interesting to consider the influence of Arab art on the Europe of the Middle Ages.

Omeiyad coins have been found in Poland, Russia, Denmark and Sweden, and in the Carlovingian period Arab sailors went out into the Atlantic. With so great a commerce there must have been an entry for that Eastern art, described by an authority as being "second to none in richness of decoration, harmony, brilliance of colour, and fantasy governed by rigourous logic." Rome took her "tree of life" and her two-headed animals from the Arab, though the griffon was originally Sassanian. Certain Arab designs are found in French and Spanish architecture, and, in the Renaissance, copper, silks and ceramics all showed Moslem influence. In Southern Italy there are traces of the same in architecture, and in bronze, silver and woodwork.

It is strange that so rich and varied an art, even if it was adapted rather than original, can have died out to so great an extent. It may be due to constant wars resulting in alien domination, to European influence, to recurring waves of puritanism, or perhaps just to the fact that, though perfected by the Arabs, it was not born in them and part of their being, as is their literature. In their present struggle for political existence, their art has no part, but their literature is, at once, an inspiration and a weapon.

The least emotion turns the townsman into an orator, the Bedouin into a poet. From earliest times the desert men have sung to encourage their camels on the long night marches, the merchants have confounded each other in the market place with their caustic rhetoric. Words often rank higher than deeds in the Arab mind, and, whereas I have never heard a warrior praised for his courage or his horsemanship, the cry "Ya Sha-ir, oh Poet!" (literally, "the man of knowledge") is the greatest honour that can be paid to a Bedouin. In ancient times each tribe had its poet, who was regarded with awe, since he was, to a certain extent, the servant of the jinns (spirits) who inspired his verse. It was his duty to hurl his satires (hija) in rhymed prose at the tribal enemy, a mixture of incantation, mockery and threat; which doubtless gave rise to the proverb, "For the wound of the tongue there is no medicine." The rhymed prose (saj) must have originated by the padding of the caravan across the desert, just as the earliest form of poem, the Qasida, reflected the nomad life of the wilderness, beginning with a description of the camp, the trials or triumphs of the journey, and ending with the praise of the tribal chief.

The first actual metre (rajaz) was a chaunt alternating two long syllables, a short and a long, and this was followed by 15 others, whose rules, however, were not confirmed till Khalil ibn Ahmad wrote in the 8th century.

The works of the most famous pre-Islamic poets, Imru ul Qais, Tarafa, Zuhair, Labid, Antara, Al-Harith and Nabigha, were collected at a later date in the seven Mu'allaqat, "the suspended." The first of these creators of the Qasida, Imru ul Qais of Kinda was a king's son, exiled for a love affair, who wandered to the Court of the Emperor Justinian in Constantinople, and was, by him, appointed Phylarch of Palestine, but was killed by a poisoned robe on his way to his new post. The Bedouin poet Antara is famous because his adventures formed the basis of the romantic epics of the middle Ages, which, in many hundred verses, deal with his legendary loves and battles. Antara was of negro blood, slave-born, yet his courage in battle made him the hero of the tribe of Abs and the adopted son of its chief. He sang of the battle of Al Faruq, "We whirled as the millstone whirls upon its axis, while our swords smashed upon the fighters' skulls," and of Abla, the Chief's daughter, "whose smile was like the sunshine flashing on swords drawn in battle."

Zuhair is generally cited by Arabs as the greatest of the seven, though some choose Imru ul Qais or Nabigha. Zuhair was a moralist, who cared nothing for flattery, "which does not ensure immortality," and his poems are serious and peculiarly honest in that they make no use of borrowed phrases, and avoid all complicated and incomprehensive simile. He came of a family of poets, for el Khansa, who wrote elegies on the deaths of her two brothers in war, was his sister, and his son Ka'b was condemned to death by Mohammed for the idolatry of his poems, and only saved himself by a panegyric which the Prophet's vanity could not resist. His father Aus Ibn Hajar wrote famous descriptions of weapons.

The Grammarian Al Asmai made another collection of the works of six of these poets at the beginning of the 9th century, but included Alqama, who wrote the famous comparison of his camel and a desert ostrich, and omitted Labid and Al Harith.

The subsequent Diwans (collections of poems) show us the gradual evolution of Arab poetry, but until the days of the Omeiyad Caliphate, the desert spirit prevailed. We have descriptions of oases, of camel skeletons, with the flesh hanging on to the bones "gleaming like the teeth of a slave girl," of single combats between tribal heroes, of tent life and, after the 4th century, of horses.

The tribe of Abs produced another hero poet, whose generosity was only rivalled by that of Hatim Tai—"I would cut up my body to feed my guests," he said. Dhul Asba al Adwani expressed an ideal for all warriors—"Use thy goods nobly; make thyself the brother of all generous men. However wide the distance never forget the debt thou owest to thy brother and the poor. Rush into battle where the most intrepid shuns the charge, and, when thou art summoned on an important matter, take all the burden of it on thee."

Of Hatim Tai's prodigious generosity there are as many fables as of the courage of Antar. As a boy he is said to have presented his grandfather's herd of camels to some passing poets, and, when he was disowned by his people for the deed, he sang: "I suffered not when Sa'd and his family departed, leaving me lonely in my home, parted from all my kin. By squandering my fortune, I have won swift glory." To-day, if Bedouins are hungry in the desert, they pray to Hatim Tai in the rhymed prose of 1,500 years ago, to provide a feast for their need.

The earliest Arab prose was unwritten, like the poetry. Story-tellers used to go from camp to camp telling the "samar," long repetitive descriptions of battle and heroic adventures.

At fairs and markets orators were urged into trials of eloquence, of which the audience were the judges. It is probable that Mohammed listened to the rival poets at the famous yearly fair of Ukaz, where a wreath was given to the victor and the winning poem pinned upon a tree. The story-teller had a choice of relating the history of some great living chief, usually the hero of his own tribe, or the fabulous adventures of a more or less mythical personage. A famous story-teller, Nadr ibn Harith of Mecca, used his knowledge of ancient Persian legend to rival the eloquence of the Prophet in the biblical stories which he used in the Koran.

Mohammed was perhaps influenced by the poets of his era, since some of their expressions (such as Umayya ibn Abu Salt's description of the day of judgment as the "day of mutual disappointment,") have passed into the Koran, but he condemned their works as idolatrous, and ordered various contemporary poets to be executed.

The Koran, which Mohammed tells us was inspired by the Archangel Jabril, (Gabriel), is the finest monument of rhymed prose, but the style varies between the early suras which consist of short verses, and the long chapters revealed at Medina, where the rhythm is only marked in the pause at the end of each verse. The present arrangement is, of course, artificial, for none of the Suras were written down during the

Prophet's lifetime. Four of his disciples are supposed to have memorised the whole revelations, and, under Omar the fourth Caliph, Zaid, who had been Mohammed's secretary, superintended the writing of the first Koran. As, however, no text was accepted unless two witnesses for its authenticity could be produced, much that was genuine was probably omitted.

The rise of the Prophet produced a new movement in Arab literature. It was first seen among the contemporary poets, who employed all their art in singing the praises of the warrior Prophet. Labid was one of the first impressed by the recitations of the Koran at Medina. He sang his conversation from paganism in similes of power and beauty, but, once a Moslem, he looked upon his poetry as heathen and refused even to talk about it.

Hasan Ibn Thabit deserves mention as the poet laureate, the "Mirror of the Prophet," but he has none of the colour of his pagan predecessors.

Only religious poetry was encouraged under the early Caliphs, but a formidable development of literature occurred in the collection and arrangement of the sayings and traditions of the Prophet.

Under the Omeiyad Caliphs, the influence of town life began to be felt in Arab poetry. The nomads still sung their improvised rhymes to the beat of their camel's hoofs, as they do to-day, but the centre of literature was the court at Damascus, and the object of the poet to acquire the patronage of prince or courtier. Poetry became artificial in its exaggerated panegyric of the ruler, or satire of the rival. Al Akhtal, who was a Christian, Ferazdaq and Jarir, were the most famous poets of the Omeiyads, and the epigrams they directed at each other were the delight of courtiers, who never dared to pronounce in favour of one for fear of encouraging the stinging satire of the others. Later generations preferred Al Akhtal on account of his finished style and his apposite expressions. His moral sentiments were possibly due to his desire for the favour of Caliph Abdal Malik, of whose house he wrote: "Terrible in their rage if they are withstood, they are the most clement of men when victory is won!"

Ferazdaq was a cynic who used his great command of language in ribald verse, often directed against women. He seems to have been a vicious libertine, a coward and a plagiarist, yet his satire was so feared that no one would bear witness against him.

Jarir was a man of Yemen, who lived in Iraq and sought the favour of Caliph Abdal Malik, denied to him on account of Akhtal's jealousy. He was a mighty fighter with his tongue, and is supposed to have crushed 43 rivals at the popular tournaments of oratory. Both Jarir and Farazdaq, rivals to the end, died in 728.

A woman poet, Leila el Akhyariya, who died in 706, is famous like her predecessor, el Khansa, the "vivandière" of Mohammed's battles, for her elegies, especially for that dedicated to her lover, Tauba ibn al Humayir. She was welcomed at the court of Abdul Melek and the Governor of Iraq, and was perhaps the best known of the women orators, poets and preachers, who flourished in the early days of Islam. Another Leila is famous in the 7th century, because of the verse written in her honour by Qais ibn Mulawwah, of the tribe of Beni Amer, known as the madman of Leila. Probably this is the most popular love poem in the Arab language, and it is constantly, if unconsciously, added to by the admirers who quote it to-day. I pointed out to one Yusuf of the Emir of Asir's household that I had never heard the verse which he was obviously improvising concerning Qais' beloved. "Oh", said he, "the man was mad, so he could not remember all about Leila!" and went on with his imitative metre.

Towards the end of the Omeiyad dynasty the contact of Moslems and Christians at Damascus gave rise to much theological literature, none of which has been preserved, but we know that Hasan Basri (d. 728) whose pupil Wasil ibn Ata founded the Mutazelite school of rationalism, was the great doctrinal leader of those days.

When the Abbassid dynasty ousted the Omeiyads and established the Caliphate at Bagdad, Arab literature began to be affected by the creative and original genius of Persia. It is curious that, while Arabic was so much the diplomatic tongue of those days that Persian scholars wrote in it, the Iraq poets, philosophers, and theologists, who made the succeeding centuries the golden age of Arab literature, were dominated by the Arian imagination of the neighbouring race. Under the new Caliphs, the greatest posts were held by Persians, and at one time the Barmekid viziers were as powerful as their Arab rulers. Tribal feuds and glories were no longer the basis of verse. The Qasida was doomed and Bedouin poetry swept back into the desert, where it remains unchanged to this day. Life became the subject of poetry, cynical, passionate and heretical. Muti ibn Ayas, of Palestine, who was protected by Ja' far, son of Caliph Mansur, wrote with depth of feeling and made the most of wide descriptive powers, but his poems are often coarse. Bashshar ibn Burd (693-783), though claimed by the Arabs, was really a Persian by blood, and he extolled his own country at the expense of Arabia. He was blind and apparently a Zoroastrian in secret, since he wrote: "The earth is dark and Fire is brilliant. Ever since it has existed men have worshipped it."

With the Persian influence came a revival of the wine songs which had existed since in pre-Islamic days, the Christian Ibads were masters of the wine trade of the Euphrates, and sung the praises of their wares as they travelled from Arab town to camp.

Abu Nuwas was the leader of the Bacchic poets of the 8th century. He went to the desert to learn the pure Bedouin tongue, and returned to the splendour of Caliph Harun's court to sing with breadth and force, not only of the grape, but of the joys of hunting, together with love lyrics and the usual panegyrics and satires. Under Caliph Mutawakkil we hear of a woman court poet called Fadl, who was also a story-teller to the harem. Her lover Said told her "Thou art like the sun that lights the world; its rays seem close to us, but who can reach it." Another woman, Mahbuba (the well-loved), composed stanzas, which she sang to her own accompaniment on a lute.

With the development of music and dancing under Mutawakkil, there were many singers who composed both verse and music, but an element of buffoonery is noticeable in the play of retort. Ibn Al Rumi, poisoned by order of the Vizier, was asked by the minister where he was going. "Where you have sent me," retorted the poet. "Give my duty to my Father" replied the Vizier, amused at his victim's perspicacity. "I am not going to hell," answered Ibn Al Rumi, and retired to his house to die.

Abu Tammam and Al Buhturi, in the middle of the 9th century, tried to revive the old poetry, and, besides collecting the Hamasa (a collection of ancient warriors' deeds published by Freytag and translated into German), wrote descriptions of the great Aleppo plain in the style of the early Bedouin poets.

In the 10th century, under the Hamdanid rule at Aleppo, we find the apotheosis of Arab literature. While Persian and Turk struggled for the military leadership at Bagdad, Saif ad Daula defended Aleppo against Byzantian Romans and patronised the greatest and last of the real Arab poets, Mutanabbi. Born at Kufa in 905, he had been brought up by the desert Bedouin, and was regarded by some of them as a new Prophet. It was in prison that he wrote his first poems, and his imagination produced such fantastic imagery that he has been criticised for "empty chatter." Nevertheless his wealth of simile is picturesque and often apt. "It was as if the soldiers saw with their ears" he wrote, describing a march in a black cloud of dust. Forty commentaries have been written about his works, and one author, confident of the poet's superiority to all others, writes: "Rhythm is subject to his will, and thoughts are his slaves."

Unfortunately his exaggerated imagery, his affectation, the preciosity of his expressions, redeemed in his case by genius, had a bad effect on his successors, and Arab poetry began to descend to false values. Al Nami succeeded Mutanabbi as Court poet at the end of the 10th century, and he is chiefly remembered for his wit, often directed against himself, as when he addressed his solitary black hair: "I say to my white hairs, which are terrified by this stranger's presence, Respect her, I entreat you. A black African spouse will not tarry long in a house where the second wife has a white skin."

In Syria, in 973, was born Abul Ala el Ma-arri, who shares with Mutenabbi, according to contemporary criticism, the position of the last great poet of Arabia. He was a pessimist and a misogynist, yet he is admired above all others by a race which has neither of these qualities.

He became blind as a child, but his memory was amazing and gave rise to many legends. His letters are remarkable, and his poems, in spite of their bitter cynicism, worthy of admiration. It is supposed by the latter Syrian critics that the quatrains of Omar Khayam are based on Abul Ala's verses on the same subject, and, in some cases, the sentiments and phrasing are almost identical. Abul Ala is supposed to have said of a free-thinking Koran which he compiled and which someone criticised, "Let it be read from the pulpits of the mosques for the next 400 years and you will be delighted with it." He was unmarried and childless, and on his tomb he had engraved: "This is the crime that my father committed against me, but which I have committed against nobody."

The 12th century saw the birth in Cairo of the well-known mystic poet Umar ibn Al Farid (born 1181). One of his odes is in praise of wine, but used as a method of achieving the sufi exaltation. In the rest of his works he describes the philosophic ecstasies of the sage in love with the Godhead, longing to be absorbed in to it.

Another Egyptian, Al Busiri (b. 1211) is famous for his ode to the Prophet's mantle which every Arab schoolboy learns by heart, and his ode to Mecca—the Mother of Cities—after the manner of the early panegyrists, but, with a few exceptions, the age of the great poets passed with the Abbassid Caliphate.

After the Koran, rhymed prose had fallen into disfavour except among the Bedouin, till Ibn Nubata (b. 946) revived it in his sermons at the court of Saif ed Daula. These dealt with the duty and glory of the jehad, the Holy War, and have served as the model for countless sermons preached throughout succeeding centuries.

Abu Bakr el Khwarazmi, nephew of the great historian Tabari, was one of the many scholars who practised the art of letter-writing, perfected by the blind Abul Ala. Of him a contemporary wrote: "Abu Bakr has learning and talent, but his friendship lasts from morning till darkness, but no later."

The word "Maqama" (seances) had for some time been used to describe the gatherings of scholars who vied with each other in rhymed orations, improvised verse and proverbs, but it was Hamadani (990 A.D.) who produced, under this name, the first volume of short stories, concerning the adventures of beggars and wastrels. He was followed by Qasim al Hariri (b. 1654) who wrote a brilliant course of 50 lectures on the adventures of the fictitious Abu Zaid, a personage who, on account of his originator's skill and ingenious fancy, is now as real to the average Arab as Harun al Rashid.

The verbal stories of desert life had changed under the Abbassids to borrowed tales from India and Persia. As early as 750, the Persian Abdallah ibn al Muqaffa had translated into Arabic "The Book of the Persian Kings," and this was followed 50 years later by translations into Arabic from Greek philosophy and ancient history. The "Thousand and one Nights" was originally based on a Persian book of the 9th century and stories from Bagdad and Egypt were added. The present form dates from about the 13th century. While at court and in the towns these borrowed tales of love and sorcery, of fantastic verses and legendary battles were very popular, the desert was producing a type of natural history fable not unlike those of La Fontaine. These were unwritten, but they have been handed down from generation to generation and are told to-day in Arabia, probably with little difference in form. Of such are the dispute between the camel and the sand grouse as to which is the cleverer, and the rivalry between the stallion and the gazelle.

The Science of the Hadith, or sayings of the Prophet, has created such a volume of Arab literature that it is impossible to treat it at any length. The earliest sincere attempt to collect the traditions in chronological order was made by Bukhari (b. 810), under the title of Sahih (the Correct) which includes 7,275 traditions out of the 600,000 from which he had to choose. Another "Sahih" is from the pen of a contemporary Abul Hussain el Muslim, and these two are accepted among the six canonical works of Islam. The other four are the Sunan (customs) by Abu Da'ud; the Jami (complete collection) of Abu Isa al Tirmidhi; the Sunan of Abdul Rahman al Nasai and the Sunan of Ibn Maja, all of them more or less contemporary. Shortly after the Science of the Hadith, arose that of the criticism of the authorities and authors of the Hadith, which produced innumerable works. Side by side with this science of tradition and criticism, jurisprudence was establishing itself, and, in the early part of the 8th century, we have the first of the four great Islamic schools of law, the Hanafite, due to Abu Hanifa ibn Thabit from Kufa. This was followed by the Malekite, Shafi'ite and Hanbalite schools, all of them established within a century, by Abu Abdallah Malik ibn Anas (b. 715), Mohamed ibn Idris al Shafi (b. 767) and Ahmad ibn Mohammed ibn Hanbal (b. 780).

respectively. All of these masters wrote books on their interpretation and use of the sayings and the traditions, which were followed by the numberless works of their pupils. These are the existing four codes of Islam to which all Sunni or orthodox Moslems belong and which are studied in the Arab universities and zawias.

Jurisprudence is, after the Koran, the favourite study of the Arab, and the basis of an Alim's education.

Probably after jurisprudence, the bulk of Arab literature is concerned with history. The earliest pre-Islamic histories are concerned with the Yemen, but they were unwritten. They were a collection of eye-witnesses reports passed on from one generation to another. The historian who eventually collects them does not criticise, but, if he gives several different stories of the same event, he states which he believes to be the best. We hear of Caliph Moawiya sending for a Yemen scholar, Abid ibn Sharya, to relate to him the history of his country, but the earliest written histories were probably the "Maghazi" dealing with the wars of Mohammed. Many Arab scholars wrote history for their own benefit and had their works destroyed at their deaths. Thus Hassam of Basra, who died in 728, wrote the sayings of the Prophet, but ordered his son to burn them. Students of Arab poetry were obliged to know the history of the heroes whose deeds and whose battles the poets sung, and the tribal genealogies often go back to Noah. Under Omar's Caliphate, genealogies were collected in towns, because of the pensions due to descendants of the Prophet. The earliest written histories are confusing, because sometimes the writers speak as if they had witnessed the event themselves, and, later, in quoting from books, they suggest that the authors had informed them verbally. Sometimes the historians make one consecutive story, but quote an authority for each portion.

Historical romances existed since very early days, and a new note was given to them by the adventures of the Prophet and his son-in-law, Ali. The story of the tragic death of Husein, attributed originally to Abu Mikhnaf has been the basis for a thousand tales, just as the life of Antara served as a model for later epics.

There were fabulous romances of the conquest of Spain by Ibn Habib, and of the fall of Egypt by Ibn Abd el Hakam, and some of these were accepted as truth by the later historians, with the result that their works are full of inaccuracies.

The romantic stories of Saif Dhul Yazan, a prince of Yemen, who was suckled by a gazelle, and of the Beni Hilal with their hero Abu Zaid, born black because his mother saw a raven defeating a flock of other birds, and prayed that her son might have its courage even if he must also have its colour, are among the best known of the romances which have grown so far from their historical origin as to leave it unrecognisable.

Ibn Ishaq, who died in 767, was the first great biographer of the Prophet, but into his work he put many fables concerning Mohammed's ancestry. "The Book of Campaigns of the Prophet," by Al Waqidi (d. 822) who is said to have had 600 chests full of books, and the Book of Classics by his pupil Ibn Sa'd are important contributions to Arab history. Al Madaini (b. 752) wrote 111 books on the history of the Caliphs and also various works on prominent women, but the famous critical historian of the period is Tabari (b. 838) who wrote the "History of the Prophets and the Kings" the first complete Arab history, which starts from creation and is mixed up with a quantity of tradition. Saladin's library in Egypt contained 1,200 copies of this work.

Tabari was the authority for later historians till 1201, when Ibn el Janzi added to his works. Masudi, in 915, started the historical romances which are so popular in the East. He was a great traveller and learned in Jewish, Roman, Indian, Persian and Christian history. His great work, from which "Golden Meadows" is taken, was in 30 volumes.

The Fihrist, belonging to the end of the 10th century, is valuable because it is a catalogue of books which, at one time, existed in the Bagdad libraries, destroyed by the Mongols in 1258, and by Tamerlane in the 16th century. The best Eastern histories came in turn from Bagdad, Spain, Alexandria and Aleppo. Whenever any great man arose we find a crowd of biographers recording his history, as in the case of Saladin, who found biographers in Persia, Syria and Egypt. Later historians included Ibn Taimiyya (b. 1263) 43 of whose works are preserved in European libraries, and who was probably the inspiration of Abdul Wahhab in his fanatical hatred of innovation: Abul feda Ismail ibn Ali (b. 1273) author of a Universal History which is little more than an abridgement of Tabari's, and the great philosophical historian Ibn Khaldoun (b. 1332) author of the "Book of Examples," which includes the history of the Arabs and neighbouring peoples; the history of the Berbers and the Moslem dynasties of North Africa and the history of the Sicilian Arabs. The premier historian of the 15th century was Maqrizi, a Syrian, author of histories of the Fatimite Caliphs and of the Mameluke Sultans, while the encyclopaedic works of Abdul Rahman el Suyuti (d. 1505) incarnate the Arab knowledge of his century.

Even the shortest review of Arab literature must include some mention of the philosophy which was enthusiastically welcomed in Arabia in the 9th century, after it had left Greece. Al Farabi, who died at Damascus in 950, wrote 70 volumes of notes on Aristotle's treatise on logic. "If I had lived in his days I should have been his first disciple," he said. Ibn Sina (b. 980) known as Avicenna, was philosopher and doctor combined, and his writings cover the whole field of Eastern learning — theology, dreams, demonology, logic, physics, mathematics and astronomy.

Avenpace, who died in 1138, writing on the highest aim of human life, and analysing the various spiritual forms to which mental activity can be directed, foreshadowed Averroes, born at Cordova (1126-1198) the great interpreter of Aristotle, who endeavoured to reconcile Moslem law and science. He wrote on the unity of intellect, on religion as a distinct personal and inward power, not subject to dogma and scientific law. Averroism was eventually rejected by pious Moslems, but accepted by the Jews. Petrach speaks of Averroes as a mad dog barking against the Church. The school finally settled at Padua, which became the centre of Averroist Aristotelism.

Another branch of Arab science which has left a great literature behind it is magic or demonology. The principal of the magic virtues contained in the names of God and in certain other names was much studied in the West, and, after the fall of Cordova, it is supposed that many books from the Arab library were taken by fugitives to Morocco, where they are preserved in the Ahmas Mts. at the Zawia of Teledi. If this is true, it would explain the peculiar study of the Ilm el Ism (Science of the Name) carried on by the Moroccan Ulema. Mulai Sadiq el Raisuni shewed me some interesting works on the subject when I was at Tazrut last August. The science originated from the passage in the Koran "God has great names—invoque him by these names and fly from those who misuse them." *i.e.*, those who attribute wrong names to God. Mohamed in one of the Hadith, said, "God has 99 names—100 minus one; those who know them will enter into paradise." It is supposed that, by using the "great name," the hundredth, all prayers are granted.

It is the great name, which is only known to a few initiates, which makes God the servant of the name, and it is written on the best talismans and amulets.

The science of the virtues of God's names is perhaps the most considerable part of Moslem magic. The list is written on amulets—each name has a special virtue. Strict Arabs never throw away written paper for fear it may contain a Name of God.

Bismillah, the first word of Koran, is supposed to have been written on the side of Adam, the wing of Gabriel, the tongue of Jesus, the seal of Solomon.

Mulai Sadiq assured me that by means of these names he could raise the Jinn, but that it had taken him 17 years to acquire such proficiency!

Egypt was conquered by Selim I. in 1517, and, with the spread of Turkish power throughout Arabia, came the decay of Arab literature and art. Like the Persians of old, the Turks had begun to use Arabic as a literary language, but, inversely, they influenced the taste of the conquered countries. Turkish songs and music came into the harems with Turkish wives. The official classes were Turkish, and so the records were in the hands of Ottomans.

Haji Khalifa, a Constantinopolitan Turk, who died about 1670, was the first to use European sources for his histories, and he compiled a huge encyclopaedia called "Doubts Cleared Up," which is a most valuable bibliography of Arabic, Persian and Turkish literature.

This short review may give some idea of the number of Arab works during the Middle Ages, but, as it was not uncommon for a historian to compose 100 or more volumes, the vastness of the field may be imagiued.

It needed some dynamic force to awake

the dormant Arab spirit and create a renaissance of their literature. There were signs of this rebirth in the 19th century, when a quantity of Arab newspapers sprang up in Egypt, Syria, Tunis, Algeria and Morocco, Constantinople, India and even Paris.

The pioneers came from Syria, and, of them, Khalil Effendi el Khoury of Damascus was the best known. Until a comparatively recent date Egyptian journalism was in Syrian hands, and the two most famous Arabic papers of to-day—"El Muqattam" and "El Ahram," are the property of Syrians. Both these journals play a great part in Eastern politics and they have subscribers all over the world. The "Muqattam" numbers 1,000 in America and 11 in Alaska.

Sheikh Jamal ed Din el Afghani and Sheikh Mohamed Abdu used to publish in Paris, half-a-century ago, an interesting pan-Arab paper, which championed many political and religious reforms -el Urwat ul Wuthba. Several papers appeared there under the despotism of Abdul Hamid, and, during the war, the French subsidised a paper called "The Future," (El Mustakbal.) At the moment the Syrian students are about to publish a periodical, written in Arabic and French, which will deal entirely with contemporary affairs in the Near East. Journalism had a vitiating effect on the prose and poetry produced during the last century, but, especially in the Lebanon, there was considerable literary activity, chiefly expressed in commentaries and criticisms of the giants of olden days. Sheikh Nasif al Yazili and Ahmed Faris al Shidyaq did good work in this way, but it was not until the national movement arose in the Arab world, that an impetus was given to original work. It is difficult to specify at what moment the religious spirit in the Middle East, which had been the dominating factor for so long gave way before the racial. During the last 20 years some of the best histories have come from Syria, and, in them, we remark a new note in which the Arab predominates over the Moslem. Besides these Rafik Bey el Azm wrote a four volume work on the Heroes of Islam, and Sheikh el Rafii, of Tripoli, compiled two magnificent volumes on the Literature of the Arabic Languages.

Jurgi Zeidan of the Lebanon, wrote, "The History of Modern Civilisation," and Emir Sheikh el Arslan, the Druse, has written a considerable amount on sociology and politics, using the simple classical style. He tried to revive the peculiar method of Ibn Muqaffa, called "sahl mumtana," easy yet difficult to imitate, in which the master wrote his Kalila wa Dimna. But it was the war which changed the whole tendency of Arab literature. The last century had proved disastrous for the Moslem world. One by one their treasured possessions had been taken from them. England, Italy and France shared in the spoils, and it looked as if a united West was bent upon despoiling an East rent by factions. The war let loose the stored resentment of the Arab world. It showed that the European nations could be played off one against another, and it broke the retrogressive doctrine of kismet. President Wilson's phrase "self-determination" was the torch which lit a flame throughout North Africa and Arabia; and King Hussein expressed the new feeling, when he asked the Christian Editor of the "Muqattam" to come and see him at Jedda with these words, "Remember that, hundreds of years ago, before Mohammed and Christ, your forefathers and mine were Arabs."

So great an upheaval of thought was bound to be reflected in Arab literature. It had perhaps been foreshadowed by the poetry of the blind Taji el Faruki, a Palestinian, who, under the tyranny of Jemal Pasha, defended the national cause and sang an awakening of the hero-spirit which had conquered the old world. From America, where so many Syrians had emigrated under Turkish rule, came a new school of writers, tainted perhaps by American journalism, but finding the motive for their patriotic and descriptive writings in the longing they felt for the Lebanon and the Hauran. Coastal Syria had benefited widely by the American colleges, where her youth had imbibed some of the democracy of the States, and this is not only reflected in the modern writings, but will doubtless influence the political future of the race. America at this moment has seventeen newspapers published in Arabic, and her Syrian and Palestinian journalists send contributions to the newspapers of a dozen Arab countries along the Mediterranean. Amin Rihani is a product of this new school, though his translations of Abul Ala have won him as much fame as his original verses. Since he has visited most of the great men of Arabia in their mountains or deserts in furtherance of Arab unity, he will probably end by being the poet laureate of the new nation. Older men, waking to find themselves as fiercely Arab as they had once been Moslem, return as far as possible to the early traditions of style.

Thus Abd el Mehsen el Kasimi from Bagdad, a son of the desert, and used to reciting long extempore poems in praise of camp life and the virtues of the wilderness, stood up one day in public and improvised 100 verses inspired with the most fiery nationalism, but using the old "rajaz" chaunt.

Kheir ed Din Zerekli, of Damascus, has written satires and critical, pessimistic poetry after the old models, but he has also experimented with new metres.

No sermon of Ibn Nubata in the 10th century urging the jehad, or Holy War, was more forcible than the last discourse of the French-appointed Sheikh el Ulema at Damascus, Salim el Bukhari. This famous preacher, announcing that he was an old man, and that he wished his face to be white at his imminent meeting with his God, violated the stringent French instructions, and preached for several hours on the need of contributing to Arab unity by accepting the Caliphate of King Hussein. Next day he was dismissed by France. Naturally the nationalist movement has produced a quantity of contemporary historians, and the rise of the Sherifian family almost as great a host of biographers. Principal among these is Mohi ed Din el Khalil, of Damascus, who went recently to Mecca to write what should be a most interesting book—The Lives of King Hussein and his sons.

Even the unwritten Bedouin literature reflects the general feeling, and the desert Arab, varying his songs in praise of his camel and its ancestors, with rhymes concerning the great figures on his horizon, introduces the phrase "the peace of Feisul" as typifying Arab freedom.

Maruf Risafi, a Bedouin who has written many Arab songs, even produced an Arabic version of the "Marseillaise." His work is typical of the force and imagination which the Nationalist poets put into their plea for freedom. Many of them are free-thinkers, and a favourite quotation at the head of a passionate appeal for tolerance and unity is Mohi ed Din el Arabi's 13th century verse :—

"My heart has become capable of every formula ;
"It is a pasture for gazelle, a convent for monks, a temple for idols,
"The pilgrims' ka-aba, the tablets of the Bible and the book of the Koran,
"I follow the religion of love- -
"Whatever way love's camels take, that is my religion and my faith."

With all these new writers we leave Arab literature in its second growth. It remains to be seen whether its final tendencies will be backwards towards the classic, or whether, influenced by Europe, its language will be modified and modernised, so that the learning of thirteen centuries will be opened to the general public. In either case its fresh inspiration should assure its future, especially as Arabic is one of the richest and most expressive languages in the world ; eloquence is the heritage of the Arab races ; and learning the quality most honoured among them.

DISCUSSION.

Brigadier-General Sir Percy Sykes, K.C.I.E., C.B., C.M.G., said he had hitherto known the lecturer as a very distinguished traveller, among the very greatest of our lady travellers. When he heard her give her lecture at the Royal Geographical Society on the wonderful expedition which she had led to Kufra, he marvelled at her courage. He did not think that she had brought out at this lecture one of the chief sources of her success, namely, her genius for understanding the mentality of the people among whom she travelled. She had stated in her lecture what a very important and predominating part the Arabs had played in mediæval Europe. It was known, for instance, that the Pope always kept an Arabic secretary, and that gave one an idea of the importance of Arabic. Another example was that which he had come across in connexion with his own Persian studies, namely, that when Harun-al-Rashid the Caliph exchanged embassies with the great European monarch, Charlemagne, he made Charlemagne the gift of an elephant, which was the first to be seen in Europe since the days of Alexander the Great and Pyrrhus. He had been much interested when, one day at the Victoria and Albert Museum, he had been telling the fact to the head of the department of textiles, who said, "I can tell you something more, namely, that when Charlemagne died, the robe in which he was wrapped had an elephant embroidered on it." That showed how enormously Charlemagne had been influenced by the gift of an elephant. Again in quite a different part of the world—in California—he had been much interested in seeing the saddlery and horsemanship of the Mexicans.

It was Arab saddlery and Arab horsemanship, which had reached the New World through Spain. The very largest point of view had to be taken—a point of view which the Royal Society of Arts stood for, and had stood for since its foundation. We in the West had to study the point of view and the literature of the nations of the East, and in that connexion the greatest possible credit was due to travellers like the lecturer.

MR. A. F. KENDRICK, Head of the Textile Department, Victoria and Albert Museum, remarked that nobody who had listened to the lecture would fail to see the great scope of it, its interest, its wide range of learning, and perhaps above all the wonderful experience it related of the countries about which the lecturer had spoken.

The subject of Arab art was a very difficult one to deal with. He was sure the lecturer would agree on that point. It always reminded him of a hedgehog; wherever one touched it seemed to prick. The question had first of all to be asked, What was Arab art? Was Arab art the right name for it, to begin with? The compromise which could be come to was that if it was called Mohammedan art one was on firmer ground. The contribution of the Arab had been largely a contribution of the sword. The influence upon art had been very considerable, but it was an influence derived from the craftsmen of the countries conquered by the Arab sword. He would draw attention to one or two points illustrating that aspect of the question. The lecturer wrote in her paper about the mosque and minaret at Samarra in Iraq, and of the mosque and minaret of Ibn Touloun at Cairo, and she derived both from earlier models. Maqrizi, an Arab historian, said that the mosque of Ibn Touloun at Cairo had been copied from the mosque at Samarra. and modern scholars who had seen those places and had noticed the foundations of the one and the building of the other were inclined to agree on that point. Samarra and Cairo were considerable distances apart.

Then there was another monument which came to one's mind—that great palace-façade of Mshatta in Syria, which had been removed not very long ago from the Syrian Desert to the museum at Berlin. Scholars had got to work at it as soon as it had been set up at Berlin. Some said that it was a Syrian Christian building belonging to the 4th or 5th century, and others maintained that it was a Mohammedan monument; the latter seemed to be the considered opinion of to-day—that it was actually a Mohammedan monument put up by one of the early Caliphs of Damascus in the 8th century. However, the question was not yet definitely decided. That as much as anything helped one to see the difficulty of the subject which had been discussed that afternoon.

The lecturer very rightly drew attention to the great influence of the Arab conquests upon textiles as upon art generally, and perhaps he might draw attention to two of those. She mentioned that the Fatimite art of Cairo formed a new style of its own; that style was exemplified in the Fatimite stuffs. It was known what they were like because there were dated pieces in London; but there was at Madrid a piece of stuff with the name of Hishâm the 2nd, who was the Caliph of Cordova in the latter part of the 10th century, with a pattern almost identical with some of those Fatimite stuffs, although certain indications precluded it from having been made in Egypt. Another illustration was that to which Sir Percy Sykes had referred—the shrine of Charlemagne, in which was found a wonderful stuff with an elephant upon it. That stuff had a Greek inscription showing clearly that it was Byzantine work and almost certainly made at Constantinople. Three or four years ago there had been found in the little seaside village of St. Josse near Calais, a piece of stuff in a shrine of St. Josse. That stuff also had an elephant, and besides that had many points of similarity to the stuff in Charlemagne's shrine; but instead of a Greek inscription it had an Arabic one, referring, so scholars stated, to a General in Khorasan in the second half of the 10th century. That was now in the Louvre. So one got those two similar stuffs, one with a Greek inscription pointing to Constantinople, and the other one with an inscription taking it right away almost to the centre of Asia.

The point he wished to make was that Mohammedan art was very diverse, and it was an art of many lands. One could trace almost a continuous chain of Mohammedan art from Spain right away to the South of China.

PROF. G. HAGOPIAN considered the lecture showed the glory of Englishwomen and English lady travellers in going to distant countries and associating with the peoples there in order to learn and study, with great personal danger to themselves, the local ideas and inspirations of the Arabs. It was difficult to believe that the Northern Arabs from Arabia had any ideas of art or architecture. They were very prone to transform Christian churches into mosques. The Turks were no different from the Arabs as far as principles of religion and conduct were concerned. One could not separate the ideas under which Turkey had governed for centuries from Arabic ideas, but there was one difference, namely, that whereas the Turks studied Arabic literature, the Koran and jurisprudence, they despised the Arabs and dominated them. Now the wheel had turned. The Arabs were finding their freedom, and judging from the papers published in the United States of America, the future of Arabia would be a different one from that of the past, however the Arabs might copy more Eastern ways of expressing themselves.

LORD LAMINGTON, G.C.M.G., G.C.I.E., in proposing a vote of thanks to the lecturer, said it required an intimate knowledge of the subject to deal with an essay such as Mrs. McGrath had read. The Royal Society of Arts was deeply indebted to her for a lecture which had meant immense knowledge and research on her part. It was doubly valuable, because it was not the outcome only of research and examination of books and libraries, but also the outcome of her remarkable travels and her personal acquaintance with the countries mentioned. She knew the characteristics of the peoples of those countries and had been able to gain experience of the life and habits of those who were connected with the great literature and art of the Arab peoples. He thought, therefore, the lecture would stand out as a monument of learning.

THE CHAIRMAN (Lord Askwith), in seconding the vote of thanks, said that the lecturer had introduced a very interesting subject, and one which was of great future importance. The Arabian movement, as he called it, or the Mohammedan movement, as Mr. Kendrick preferred to style it, was one of those curious movements in the world which fascinated man, and also affected millions of human beings. History had yet to show how it had really arisen, but it had come from a central movement in the midst of very ancient countries, each with its own history and great riches (which certainly must have proved an attraction to the Arabs when they had first commenced) and with little or no belief in any particular thing, except in the lands where Christianity was still a struggling movement. It had come with a great cry of Mohammedanism which had appealed to men's minds and which had appealed also to many ancient beliefs. They went forth with the cry "There is but one God and Mahammed is his prophet." Naturally a comparatively small number of people with the sword in their hand, and with no knowledge of great buildings, could not, unless they had taken with them the peoples of the countries where they went, have had such an immense influence upon such vast territory. They adapted the Christian Church of Sta. Sophia, or temples in other parts to their own purposes. They used in Egypt the columns of the Roman period. They covered them to a certain extent with what they knew of themselves, skill of decoration, beauty of colour and a most extraordinary varied intricacy of design, and they had a certain cohesion in their vast territories by means of the religious element. But each portion of it broke away and had in subsequent times a history of its own. Spain was very different from Iraq, Iraq different from Persia, and one found, although one or other of those divisions might have become prominent in a particular kind of art and impressed itself upon the rest, that each had its own history. As the lecturer had pointed out, the confines of that vast Empire perhaps might exercise enormous influence on the adjoining lands. The Abbassid dynasty came and impressed itself with Persian views upon Iraq, even while the Arabic was still very prominent in Persia. So in Spain, the Christian religion dominated there after struggles which lasted for so many centuries. So it was that there came a time when there was not so much cohesion, but when those divisions were working upon their own. Through all that period one interesting thing was how those people, singing of their own deeds, writing histories of their own deeds, brought together a desire of poetry, and of history, and, in order to obtain a common law, of jurisprudence, and in each art or profession produced some very remarkable men. All those things must have had their origin before—particularly poetry. As the lecturer pointed out, poetry even survived Mohammed, who condemned such work as idolatrous, and ordered various contemporary poets to be executed. Yet the Arabs went on with their poetry and the poet turned Mohammed into a sort of God to be praised, and the historian into one of whom their books were to be written. It might have been that a further cohesion might have arisen through the philosophical writers if a puritanical movement or a Mohammedan new movement had not come to overthrow the adoption by the Arabs of the greatest of them, and it might have been that possibly the idea of magic might have spread—a remnant as it must have been of the worship of some of those tribes in previous days. But the Ottoman Turk came and there seemed to come a cessation of the prominent Arab movement. It had now awakened again. We were seeing it before us day by day. We should see it in the next few score years still more powerful, and it would be a movement undoubtedly coloured by the influence of those Arabs and cognate races who had emigrated to the New World, and who still retained their love of the desert and of the old. They had newspapers and writings poured forth in America and pouring forth even now in Europe. Whether the New World could come to redress the balance of the Old as regarded Arabia remained to be seen.

NOTES ON BOOKS.

THE LONDONER'S EDUCATION. London: Hodder and Stoughton, Ltd. 9d. net.

This popular handbook is one of a series on the work of the London County Council and what it does for London. Whoever conceived the idea of the series is to be warmly congratulated, for the ratepayer will certainly pay his rates more readily after glancing at this booklet than he has ever done before. If any one is inclined to grudge the money spent in London on education, let him read these extracts from official reports made before elementary education was made compulsory:

"The streets were swarming with waifs and strays, who had never attended school, a large number of whom habitually frequented the riverside, the London railway termini, the purlieus of Drury Lane and Seven Dials, streets and corners off Holborn and the Strand, and the neighbourhoods of the Borough, Whitechapel and many similar parts of the Metropolis. The children slept together in gangs in such places as the Adelphi Arches, in empty boxes or boilers, at Bankside in empty packing cases, down the 'Shades,' covered with tarpaulins and old sacks."

"The children's lives were a constant round of sunless drudgery—they never played as children play, they never seemed to think; they were prematurely old, and the victims of an awful cruelty. . . Their mortality was high."

Let him contrast this dreadful state of things with what he will find described in this handbook—bright and cheerful schools, and happy children learning not only lessons but, what is almost equally important for them, games that teach self-control and team-work, and then let him consider whether the cost of the change is too high. That it is high no one can deny. The London County Council's education service costs annually £12,600,000; it employs 30,000 teachers and officials; but it educates 1,000,000 people. Last year the youngest child at school was scarcely two years old—a baby in a nursery school; the oldest student at school was 78—a grandmother and a keen student at a women's institute.

A fair idea of the way in which the money is spent will be gained from this handbook, which tells briefly what is being done in the elementary and central schools, in the special schools for the afflicted, the arrangements for the physical care of the children, and for technical education and lastly how with the aid of scholarships clever children may find their way to secondary schools and thence to the universities.

THE WORLD'S COTTON SUPPLY.*

By Sir Charles W. Macara, Bt.

Everyone should be interested in rescuing the largest of our manufacturing and exporting industries from the disastrous position into which it has fallen, mainly through lack of vision in dealing with the conditions brought about by the world crisis through which we are passing. The outstanding fact, is that we must have more and cheaper cotton, and, further, we must not rely on America for our supplies to the same extent as we have done in the past.

The Cotton Crop Reporting Mission, sent to America last year by the International Cotton Federation, pointed out that the cotton States east of the Mississippi are no longer able to supply cotton on an economic basis which will enable Lancashire to supply the normal quantities of cotton goods to the agricultural populations of India and China, "inasmuch as agricultural produce in these countries is being sold at or near pre-war prices, while American cotton is above 200 per cent. of the pre-war rate."

The conclusion the Mission arrived at was that America would not be in a position to supply cotton at a cheap rate for years to come, if at all, and that America, in any case, has now not the least chance of competing with British possessions or with countries like Brazil, Peru, etc., in the raising of cotton.

The Mission does not expect more than about 9,500,000 bales to be raised in America in any normal year in the future. When it is remembered that American mills are now using 6,250,000 bales a year of their own cotton, with every prospect of increasing that quantity, it will be seen that there can be little left for the rest of the world in coming years.

Personally, I consider this estimate of future American crops to be somewhat pessimistic, but it shows, at all events, the urgency there is for the growing of more cotton both in the British Empire and elsewhere.

It is only since the International Cotton Federation began to turn its attention to India that the possibilities of that country have been fully realised. As showing what can be done there, it is but necessary to point out that the Indian cotton crop was raised from 3,000,000 to 6,000,000 bales in the ten years before the war, and had not the war intervened it was estimated that it would have been possible in a very short time to raise the crop to 10,000,000 bales of 400 lbs. each, which is in the neighbourhood of the total crop America has been raising in recent years.

A small proportion of the Indian crop has hitherto been found suitable for the mills of Lancashire, but Indian cotton is suitable either for the Far East or the Continent of Europe, and those who buy it leave so much more of the better qualities for the English market. The production of countries outside America is steadily improving. and Lancashire is finding it possible to use more and more of these "outside growths." While the import of growths other than American into Great Britain was but 26 per cent. of the whole in the 1920-21 season, the daily trading at Liverpool last year showed that British spinners were taking 50 per cent. of non-American growths.

What is known as "American" cotton is not indigenous to America, and can be grown where the soil and climate are suitable. In India, for example, the Government Departments of Agriculture are now taking the keenest interest in promoting the cultivation of improved varieties of cotton, and the Punjab alone is expected to increase its crop of cotton grown from American seed this season by something like 50,000 bales. Not very long ago Lancashire's takings of Indian cotton were comparatively small, but, according to Liverpool Cotton Association figures, the imports into England of Indian cotton from 1st August, 1923, to the middle of February, 1924, totalled 138,711 bales, and practically the whole of this cotton went to Lancashire mills. The products of Brazil, Peru and other countries are being used in Lancashire more and more.

Magnificent strides are being made in the Anglo-Egyptian Sudan, where all records in production, it is expected, will be eclipsed this year; much progress is being made, also, in India and elsewhere, and new fields are opening up in all parts of the Empire where cotton growing is possible; but, apart from these enterprises, we see signs of

---

*Abridgment of article in the *Financial Times*.

development in almost every part of the globe where cotton can be grown.

Meantime, it is to be hoped that while we are improving our supplies of the raw material we shall cease to scramble for the limited trade that is coming to us from abroad, and especially from the Far East, under present conditions, and that we shall take steps to control our output scientifically and cease to ruin ourselves by senselessly competing for the greatly reduced volume of business available.

VICTORIA AND ALBERT MUSEUM.

The Victoria and Albert Museum has acquired two important pieces of English furniture from the collection of the late Colonel H. H. Mulliner, given by Mrs. Mulliner in his memory. One of the objects consists of a small commode of serpentine shape, enclosed with folding doors, veneered with satinwood and rosewood, and decorated with festoons and trophies of musical instruments inlaid in other woods. The angles are fitted with finely modelled mounts of gilt metal. This type of furniture was made by Chippendale and other English cabinet-makers about the year 1770, and follows to a certain extent the French style of Louis XV., with which it may not unjustly be compared for excellence of workmanship.

The second object is a small dressing-table of the same period, also veneered with panels of satinwood and inlaid with classical vases, festoons, foliage, etc., in woods of various colours. The table is of ingenious construction. The drawer in front, which contains a mirror and two receptacles for toilet articles, can only be partially pulled out until it is released by sliding back the top of the table. The lids of the drawers are inlaid with heads of a man and woman in Eastern costume. The feet are mounted in brass, chased and gilt.

These objects are at present temporarily exhibited in the West Hall of the Museum.

In the same Court has now been placed on exhibition a typical shop-front from No. 32, Petty France, Westminster, a locality which for eight years was the dwelling place of Milton. This shop-front, which was handed over to the Museum by the War Office at the time of the recent demolition of houses in this street, is of pinewood, and the bow window is supported on iron brackets and surmounted with a cornice, enriched with finely modelled egg-and-tongue and leaf ornament. The period to which it belongs is that of the second half of the 18th century and it represents a class of domestic architecture which is now fast disappearing.

GENERAL NOTES.

Conference on Illumination.—A Conference on Illuminating Engineering will take place at the British Empire Exhibition on August 12th. A report of the proceedings at the meeting of the International Illumination Commission and at the First International Conference on Industrial Hygiene, recently held in Geneva, will be presented, and developments in connexion with the lighting of schools and factories will be discussed. The other subjects to be considered include public lighting and the lighting of exhibitions. A paper entitled the "Illumination of Highways from the Motorist's point of view" will be read by Mr. Edward H. Fryer (Roads Dept., Automobile Association), and Mr. Haydn T. Harrison will deal with some features of the lighting of exhibitions. The Conference will be open to all interested in the subject of illumination, and tickets can be obtained from the Hon. Secretary of the Illuminating Engineering Society, Mr. L. Gaster, 32, Victoria Street, S.W. 1.

Reclamation of the Zuyder Zee.—In his recent report on the financial, industrial and economic conditions of the Netherlands, the Commercial Secretary to H.M. Legation at The Hague states that the preliminary work on the reclamation of the Zuyder Zee was continued during 1923, efforts being concentrated on the tract between Weiringen and the mainland. Boring was continued in order to arrive at the most suitable position for the main dam, but no definite steps were taken to begin this work. It should be borne in mind that since the original estimate was made conditions have changed. Although prices of material required in the reclamation may have declined as well as those of labour, which was one of the reasons why at one time abandonment of the plan was urged, it is feared that, now prices for agricultural produce may decline further, the land reclaimed cannot be profitable exploited.

Gum Copal from the Philippine Islands.—Although there are many hundreds of grades of gum copal, varying according to colour and size, there are two major divisions—the copal that is taken from the ground, where it has lain possibly for centuries and become solid, and that which is tapped from the trees and is softer and not so desirable for making varnish. According to the United States Trade Commissioner at Manila, the gum reaches Manila through Chinese channels, where it is sold to exporters. It arrives in a very dirty condition, and the expense of cleaning and grading, as well as the inland transportation, constitutes a large portion of the export price. Philippine gum copal is not favourably regarded in the American market. Much of it has been shipped to Singapore. German firms, re-established in Manila since the war, however, have placed considerable quantities in the United States.

FOR SALE.—Painting by the late Mr. Charles Conder.—For particulars, apply M., c/o The Journal of the Royal Society of Arts, John Street, Adelphi, London, W.C.

Journal of the Royal Society of Arts.

No. 3,743. VOL. LXXII.

FRIDAY, AUGUST 15, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.2.

NOTICE.

COMPETITION OF INDUSTRIAL DESIGNS.

The Exhibition of selected works submitted at the Society's Annual Competition of Industrial Designs is now being held, by the courtesy of the Director, in the North Court of the Victoria and Albert Museum, South Kensington, S.W., and will remain open until Saturday, August 30th. The designs exhibited are divided into the following classes: Textiles, Furniture, Book Production, Pottery and Glass, and Miscellaneous. The Exhibition is open to the public free daily from 10 a.m. to 5 p.m., and on Thursdays and Saturdays from 10 a.m. to 9 p.m.

PROCEEDINGS OF THE SOCIETY.

DOMINIONS AND COLONIES SECTION.

MONDAY, 16TH JUNE, 1924.

SIR RICHARD REDMAYNE, K.C.B., M.Sc., M.Inst.C.E., M.I.M.E., M.I.M.M., F.G.S., Chairman-Governor, Imperial Resources Bureau, in the chair

THE CHAIRMAN, in introducing the reader of the paper, said Dr. Corless's knowledge of his subject was exhaustive. Not only had Dr. Corless a distinguished career at the McGill University, being the holder of several very high academic honours, but he was a thoroughly practical mining engineer and metallurgist.

The paper read was:—

MINERAL WEALTH OF THE PRE-CAMBRIAN IN CANADA.

By C. V. CORLESS, M.Sc., LL.D.,
Director and Manager of the Mond Nickel Company, Limited.

I.—INTRODUCTORY.

Canada is a country of vast area. It is slightly larger than the mainland of Europe; roughly 25 per cent. greater in area than either the United States or Australia; more than 70 times as large as England; and nearly equal to one-third of the pre-war British Empire. It is not surprising that the relative importance of the various natural resources of so vast an area is being revealed but slowly, even to Canadians. It is still less surprising if their relative extent is almost unknown in Great Britain.

History has contributed not a little to this failure to grasp the relative value of the resources of this half of North America. In the early settlement of the continent Spain occupied the southern third in latitude; Britain, the east coast of the middle third; and France, astride the great waterway leading to the heart of the continent, claimed possession of the northern third. But Britain, in persistent search for a shorter route to the land of silks and spices, explored and took possession of a great region of furs. The extraordinary commercial success of the Hudson's Bay Company, at the same time that it enriched its shareholders, stamped Canada as a land of snow and ice; and first impressions are most enduring. Nearly a century of petty rivalry followed between the fur-traders on the St. Lawrence and those on Hudson Bay, and then this local strife became an insignificant side issue in the world-wide maritime and colonial struggle between Britain and France, which ended by laying the foundation of the British Empire in Canada and in India. Not less really, though perhaps more obscurely, the foundation of Modern Germany—and so, of the late German Empire—was laid at the same time, by the steadfast resistance of Prussia, under Frederick the Great. Thus was unconsciously effected the transference of rivalry which has culminated in world-wide disaster a century and a half later. But, if Britain in this struggle won a half continent, her attempt to share part of the cost with the neighbouring colonies soon lost her the other half. Thus a decision, which was of slight inherent importance,

but which contravened a great principle, became a turning-point of vast import in history.

The fight for American Independence, of which this unwise decision was the occasion, if not fundamentally the cause, gave rise to a considerable emigration of loyalists into southern and eastern Ontario, two of the three greater plains of fertility in Canada, and thus confirmed the growing view that Canada is essentially agricultural. Finally, with the consolidation of the scattered provinces of Canada into a confederation, a half century ago, a physical bond of union became a necessity, if the partnership was to become more than a name, and, for so young a nation, the herculean task of constructing a transcontinental railway was undertaken. This railway, the justly famous Canadian Pacific, opened up for settlement, at its widest part, Canada's largest northward extension of the great central continental plain—a wheat-growing territory second to none in the world. Now in London, of all places in the United Kingdom, the fact is ever before you that Britain is a small island, heavily over-populated as a result of the recent industrial revolution, and therefore a great importer of foodstuffs. What more natural than that the crowded population of Britain, seeing Canada's exportable surplus of wheat leap upward by the hundred million bushels, should fix attention on Canada's agricultural areas, and should form a view of their relative importance out of proportion to the actual geographic, physiographic, and geologic conditions?

Furs, timber, farm products—these in natural order of development, as well as in ascending order of importance, have come to be regarded as Canada's greatest natural resources. The visitor to Canada from abroad, making his stay at Montreal, Toronto, or Winnipeg, situated respectively in the three northward extensions into Canada of the great central continental plain—that vast expanse of fertile lowland stretching northward from the Gulf of Mexico—not realising that at or near the Canadian boundary this northward-expanding area suddenly shrinks, readily accepts the prevailing view that Canada is, and will remain, first of all a land of fertile farms. If, reflecting on the limitation of his own observations, he turns to the article on Agriculture in Canada in the *Encyclopædia Britannica*, he will find that the impressions created by the immigration literature he may have seen before sailing are confirmed by the opening statement: "Canada is pre-eminently an argicultural country." But, if he makes a real study of the country, it will come as a rude shock when he discovers that because of recent glaciation, mountainous surface, or climatic conditions, not more than about 15 per cent. of its entire area is suitable for profitable cultivation.

II. THE AGRICULTURAL PART OF CANADA.

But, lest your minds be carried too far in the opposite direction, I hasten to add that only about one-third of this area has up to the present been brought under cultivation. This 15 per cent., though a relatively small part of Canada, is yet more than ten times the area of England; it comprises about 350 million acres. It is about one-third of the area of land suitable for cultivation in the United States. Setting aside one-seventh of this area for roads, railways, towns, cities, villages, and other conveniences and necessities of civilisation, this cultivable area will easily support a farming population of 15 millions with profit and without discomfort, if we allow 100 acres as the average farm unit, and assume the average rural family to be five. This might easily be the rural basis of a national population of 50 or even of 75 millions.

III. THE NON-AGRICULTURAL PART OF CANADA.

What of the remaining 85 per cent. of Canada? It would be a matter of great interest, had we time to consider Canada's timber resources and great mineral possibilities as a whole, not forgetting her resources in coal and lignite, estimated by geologists to exceed the total fuel reserves of Europe by 60 per cent., and to be probably 75 per cent. of the solid fuel resources of the entire British Empire. But we shall do better to confine our attention for the time at our disposal to Canada's vast pre-Cambrian area, the greatest physiographical and geological feature of the country, to which is chiefly due its agricultural limitations, and which is the fundamental cause of many of Canada's most serious national problems. It is this vast feature which, eastward from Winnipeg, blocks the extension northward of the great central North American plain, confining it to two small, though important, farming areas:

southern Quebec and the southern tip of Ontario. It is this also which narrows the largest extension of this plain northward into Canada to a wedge-shaped area, having a base of less than 800 miles at the international boundary and tapering to a mere valley between the pre-Cambrian and the Cordilleran highland of the Yukon, along the lower reaches of Mackenzie River, well within the Arctic Circle. It is this pre-Cambrain area, popularly known as the Laurentian Highland, equal in total area, to 60 per cent. or more of Canada's mainland; so little known; so misunderstood; hitherto, generally regarded as a "barrier" or a "wilderness" to be crossed in order to reach Canada's western plains; so great a source of the nation's economic, social and political problems; to which I wish to invite your studious attention for the remainder of this discourse.

IV. OUTLINE, FORM, AND EXTENT OF THE PRE-CAMBRIAN.

If you have ever sailed to Montreal via the St. of Belle Isle, passing to the north of the island of Anticosti, as the steamships occasionally do, you obtained a first glimpse of the pre-Cambrian on entering the strait, and followed its bold and rather forbidding shore line for 800 miles, to a point a few miles east of Quebec City. From this point to Montreal, its southern rim is never more than 30 miles from the north shore. For about 1,000 miles, strait, gulf and river may be considered as marking the contact between rock formations of this most ancient geological era, and those of more recent eras. If from Montreal you follow the Ottawa tributary of the St. Lawrence westward for about 175 miles, you will observe from the window of the Canadian Pacific Railway train, the rim of the pre-Cambrian Shield following the opposite shore of the river, which, for this distance, marks the contact. Then turning abruptly southward you will follow the irregular contact across the narrow eastern extension of Ontario, of rather less than 5,000 square miles, lying between main river and affluent, and cut off geologically from the larger southern plain of the province by this south-eastward spur of the pre-Cambrian. This triangle of farming land in eastern Ontario and the fine fertile area in southern Quebec, passed to your left as you ascended the St. Lawrence from Quebec City to Montreal, constitute together the first of the northward extensions into Canada of the central continental plain, already alluded to, comprising between 15 and 20 thousand square miles. The pre-Cambrian spur crosses the St. Lawrence, forming part of the beautiful "Thousand Islands," at the outlet of Lake Ontario, and spreads out over an area of roughly 10,000 square miles, forming the Adirondack Mountains of New York State.

Continuing our circuit around the Canadian Shield, we follow the St. Lawrence across the neck of the Spur for 40 or 50 miles to a point near the city of Kingston, and from this city proceed nearly due westward to Georgian Bay, a distance of about 175 miles in a straight line. To the south and south-west of this line lies the second of the extensions into Canada of the continental plain—the arrow-head peninsula of southern Ontario; nearly surrounded by the three Great Lakes, Ontario, Erie, Huron, and their connecting waters; and comprising about 25,000 square miles of very fertile and highly developed farming land.

Small as these two northward extensions are, their combined area being about two per cent. of that of the Canadian Shield, or slightly over one per cent. of Canada, they yet contain probably half of the present total population of the country, with ownership or control of more than half of its developed wealth.

From the point at which we reached Georgian Bay, the outer rim of the Canadian part of the pre-Cambrian Shield follows the shore line of the bay and the two Great Lakes, Huron and Superior, to the intersection of the latter shore with the international boundary, thence this boundary to a point ten or fifteen miles west of the boundary between Ontario and Manitoba. Turning north-westerly the rim continues for about 425 miles in nearly a straight line, sixty per cent. of which coincides with the eastern shore of Lake Winnipeg. At a point about 50 miles north of this lake, the outer contact of the Shield turns sharply to the west, crosses the province of Saskatchewan, and again curving with a wide sweep more north westerly, clips a corner of about 2,000 square miles off the most westerly prairie province, Alberta, the province which contains about 70 per cent. of the Empire's estimated coal resources. Of the three so-called prairie provinces, the pre-Cambrian Shield occupies roughly two-thirds of Manitoba, one-third of Saskatchewan and this corner of Alberta.

From the intersection of the outer rim of the shield with the 60th parallel of north latitude, 600 miles west of Hudson Bay, the outer contact of the pre-Cambrian continues north westerly for 800 miles, nearly to the Arctic Ocean, including in the Shield roughly one-half of the great marginal glacial lakes, Great Slave and Great Bear, each of which is about 50 per cent. larger than Lake Ontario, on which Toronto is situated. This last 800 miles is in the mainland part of the unorganised North West Territories. of which the pre-Cambrian occupies roughly two-thirds, or about 500,000 square miles.

The pre-Cambrian also occupies the southern or south-eastern parts of some of the large islands in the Arctic Archipelago, north of Canada, to the extent perhaps of 200 or 250 thousand square miles, though naturally this area is not yet accurately known.

From the most north-westerly point of the Shield, near the Arctic Ocean, only about 400 miles from Alaska, and therefore almost in the extreme north-west corner of Canada, the distance to the entrance to Belle Isle Strait, measured in a straight line, is 2,500 miles, divided equally by the broad 350-mile opening into Hudson Bay, which, with its northern extension of 350 miles, Fox Channel, and its southern extension of the same measurement, James Bay, has a total length of 1,300 miles, a maximum width of 600 miles and a total area of more than twice that of the North Sea. This large mediterranean sea, penetrating to the heart of the Shield, imparts to its inner rim the appearance of a great horse-shoe; the outer rim, which we have traced, is somewhat similar to a wide V, each limb being more than 1,500 miles in length, and the roughly truncated angle pointing southward.

A broad and clear view of the greater facts connected with the geographical position and extent of this vast physical and geographical feature is so essential to a proper understanding of Canada that, even at the risk of wearying you, I am tempted to present these greater facts from a slightly different angle.

Approaching Canada from the west we come first to the very mountainous Cordilleran Plateau, or Pacific Highland, averaging 400 miles wide, stretching about 1,500 miles from the international boundary to the Arctic Ocean, and comprising British Columbia, Yukon territory and a narrow adjacent strip in Alberta and North West Territory. This highland we may consider as approximately 600,000 square miles in area.

Next eastward we come to the greatest of the three northward extensions of the central continental plain; roughly wedge-shaped, with the base somewhat less than 800 miles wide at the international boundary, measured from near Winnipeg to the Rocky Mountains; tapering northwestward and reaching the Arctic Ocean in about 1,650 miles; narrowing to 400 miles or less at 60° north latitude, the boundary between the four western provinces and the two northern territories; and finally contracting to little more than the valley of Mackenzie River. The southern part of this extension of the central plain comprises easily 70 per cent. of Canada's total area suitable for profitable cultivation. The area of the whole extension is about 650,000 square miles.

The eastern boundary of the plain is the vast pre-Cambrian Shield, occupying 85 per cent. of the entire surface of Canada east of the marginal lakes between plain and shield, Great Bear, Great Slave and Winnipeg. The remaining fifteen per cent. comprises: (1) a narrow area along the Arctic coast stretching westward from Coronation Gulf; (2) a belt of later formations (Ordovician, Silurian and Devonian) lying south and west of James Bay and south of Hudson Bay, covering roughly 100,000 square miles, of which three-fourths is in Ontario and one-fourth in Manitoba; (3) the two parts of southern Ontario, about 30,000 square miles; (4) southern Quebec, about 40,000 square miles; (5) the three maritime provinces, totalling a little over 50,000 square miles; and (6) a few small remnants of later formations within the Shield, of probably negligible area. Thus, while the Shield fills about 1¾ million square miles of all the mainland of Canada lying to the east of a line stretching north-westerly from near Winnipeg to a point within about 400 miles of Alaska near the Arctic Ocean; there remain in all this great eastern part of Canada, exclusive of the pre-Cambrian, only the relatively small areas mentioned; and even of these only southern Ontario, southern Quebec and the Maritime Provinces, totalling in all about 120,000 square miles, account for most of the history of the country from its discovery down to 50 years ago. Summing up, we see that this vast physical and geological feature fills two-thirds of the mainland of the North West Territories; a corner of Alberta; one-third of Saskatchewan; two-thirds of Manitoba; three-fourths of Ontario; and nearly ninety-five per cent. of Quebec. The only provinces untouched by it are British Columbia and the Maritime Group.

Now, the Pacific Highland and the three northward extensions of the continental plain, as well as the Appalachian extension into south-eastern Quebec and the Maritime Provinces, are all continuations into Canada of the three great physical features filling nearly the entire surface of the United States. In most places the dividing line is merely a survey line. The development of each of these in Canada has shown the the assimilating effect of this relationship, in some cases very strongly. The one distinctive physical feature of Canada, and that, too, of the vast area and in the important geographical position we have outlined, the feature which has in its development the possibilities of making the Canadian nation really different from, and therefore more valuable to, the American nation, but the feature which, until very recently, the Canadian people have almost ignored or regarded as an obstruction to their progress, and which is even yet inadequately known and appreciated; this unique feature is the pre-Cambrian Shield.

It would be a matter of much interest, if time permitted, to trace the effects of glaciation over this great area; to depict its low smoothed and rounded hills of bare rock, frequently bearing striations not yet weathered out, resulting from the slowly moving ice-sheet; to examine the demoralised drainage, left, on the final retreat of the ice northward, in the form of myriads of crystal lakes, numberless streams and rivers with countless rapids, cascades and waterfalls, and innumerable peat bogs and muskegs; to note how, here and there, temporary damming by the ice during its last retreat created equally short-lived or temporarily extended lakes, in some places of considerable extent, on the beds of which glacial silt prepared the future surface for farming; to observe the dribble of drift left as a mantle over much of the surface as the ice made its last retreat before the brief period in which we are living; to study the farming and forest resources of the area—the former extending over perhaps 10 per cent. of the southern fourth of the Shield and the latter over roughly the southern third; to estimate the economic value of the disorganised drainage in the developed and potential water-powers, in the facilities afforded for transporting logs to the numerous lumber, pulp, and paper mills, and in the scenic and sporting possibilities created in the area; to consider the climate and to outline the general geology of this great area. But we must confine our attention almost exclusively to the immense potential mineral wea'th of the pre-Cambrian, made possible of discovery by the removal through glaciation of the deep covering of decayed rocks and soil which must have accumulated through ages of weathering, noting any of these other interesting matters only in so far as such references will cast light on the mineral wealth of the Shield.

V. Some Fundamental Principles Necessary in Estimating Mineral Wealth.

When we study a vast territory such as this, much of it remaining practically unexplored, and of the remainder, only a few square miles here and there exhaustively searched for economic minerals, we shall miss our main object if we fix our minds on achievement, rather than on what past achievement signifies. The use of well-balanced judgment, in conjunction with inductive and deductive reasoning, is an absolute necessity, if the future possibilities of so great a territory are ever to be grasped. For most mineral resources differ in a very important respect from land and forest resources. They must be discovered; and discovery is generally an uncertain and costly undertaking, even after the assistance of the prospector is accepted in finding the first clues.

The search for minerals in a well mineralised area is a class of enterprise which generally can be converted from mere gambling into a serious business, by taking sufficient chances to eliminate the chance of total failure. On the average, hundreds of mineral claims must be examined, dozens trenched and sampled, and many tested by drilling or other costly work, for each discovery of an ore body that will develop into a flourishing mine. But the use of experienced judgment, based on accurate observation and clear reasoning, and backed by sufficient technical knowledge, energy, persistence, and financial resources, is the only sure means for converting into sound business what would otherwise amount merely to taking a gambling chance.

VI. THE PRE-CAMBRIAN IRON ORE AREAS IN THE UNITED STATES.

In making our imaginary trip around the outer rim of the Shield, we noted a spur from the main area into New York State. When we followed the shore of Lake Superior, and later the international boundary, to Manitoba, we crossed a second projection of the pre-Cambrian into Michigan, Wisconsin and Minnesota States. The former spur is said to contain very large reserves of iron ore, figures of more than 1,500 millions of tons being given for these. But the latter, to the south and west of Lake Superior, contains the deposits known as the Lake Superior Iron Ores, which have given the United States a lead so great that in several recent years that country alone has produced more than half of the world's total output of both pig iron and steel. For many years more than 80%, and in some years close to 90%, of the total output of iron and steel in the United States has been obtained from the reduction of Lake Superior ores. For the past 10 years this district has produced an annual average, in round numbers, of 50 million tons of iron ore. The total production for the district to date is above 1,100 million tons of ore, and it has been estimated that double this tonnage remains in reserve. In addition to these reserves of iron ore of suitable grade for direct smelting, there remain, practically untouched, enormous reserves, estimated by well-known iron ore geologists at an almost unbelievably large figure, about 70 thousand million tons, of lower grade ores, which will require beneficiating before smelting. This problem is being attacked on a large scale at the present time by a group of distinguished American mining engineers, some of whom have been highly successful in other very large low-grade mining enterprises.

We thus see that this small projection of the pre-Cambrian (not more than 2 or 3 per cent. of the area in Canada) has been, and will long remain, the very foundation of the enormous industrial expansion of that famous manufacturing region, comprising less than one-eighth of the area of the United States, containing not far from half the population, much of it crowded into a score of great cities, in a dozen of which dwell more than 20 million people—a quadrilateral whose western limit is the Mississippi River from the Twin Cities to St. Louis, and whose eastern boundary is the Atlantic seaboard from Boston to Baltimore—the greatest hive of prosperous industry, the home of the most intense energy and of the largest scale enterprise, and the seat of the greatest concentration of wealth the world has ever known. Great as this remarkable quadrilateral might otherwise have been, there is no denying that the very key to its present inestimable importance is to be found in the vast deposits of iron ore in that relatively small corner of the pre-Cambrian, south and west of Lake Superior.

VII. THE PRE-CAMBRIAN COPPER MINES IN MICHIGAN.

But the iron resources of this enormously productive mining area are only a part of its mineral wealth. The most northerly part of Michigan, the Keweenaw Peninsula, projecting like a finger to the centre of Lake Superior, contains the famous Lake Superior copper deposits, which have been systematically mined for 75 years. These deposits of native copper during the past quarter of a century have produced nearly 5,000 million pounds of the highest grade copper marketed. For the sixteen years prior to the post-war slump in 1920, their average annual production was 220 million pounds; and for the past 20 years, including the recent four years of severe curtailment, their annual production has averaged approximately 200 million pounds. The proven ore reserves remaining are very large, and the possibilities of discovery of additional reserves in the so-called copper range, both at greater depth and along the range, are said, as a result of recent geological researches, to be very great.

True, the Lake Superior iron and copper deposits are not in Canada. But, in seeking to interpret so vast an area as the pre-Cambrian in Canada, about the greater part of which very little is known in detail, there is every reason for accepting information regarding any part of the Shield, no matter what its source. The more intensive examination and development of the smaller areas in the United States, even though the two projections from the Shield into that country total only about 3 per cent. of the part in Canada, will broaden the basis of our later inference very materially.

VIII. THE PRE-CAMBRIAN MINERAL AREA NORTH OF LAKE HURON.

Having fixed in our minds a few of the outstanding facts regarding the iron and copper resources of these pre-Cambrian areas in the United States, let us next consider, as fully as time will permit, the mineral discoveries and mining developments in this area in Canada.

Boarding a train on the South Shore Line south of the Copper Range, we may profitably pause, after a 250-mile run eastward, at Sault Ste. Marie. The canals, Canadian and American, constructed at this point to take shipping past the drop from Lake Superior to Lake Huron, during the 7 or 8 months' season of navigation, pass three times the tonnage annually taken care of by the Suez Canal. The greater part of this freight is iron ore from Lake Superior ports en route chiefly to Lake Erie ports, to supply the blast furnaces from Detroit to Buffalo and those of the Ohio Valley, centering largely on Pittsburg.

Again boarding an east-bound train on the Soo Branch of the Canadian Pacific Railway, we pass through an area widely mineralised with both gold and copper. Many claims of each have been staked and a few have been worked in a comparatively small way with moderate success. The copper ore is generally chalcopyrite in quartz veins, entirely free of gold or silver, or with mere traces of these metals. The company with which I have been associated for 20 years, the Mond Nickel Company, has used many thousands of tons of these ores, partly purchased from various producers on a small scale, and partly taken from the old Bruce Mines, which it owns, as flux for the iron in the copper-nickel bessemerising process, the copper of the flux being recovered incidentally in the bessemer matte. It is quite possible that the ore from some of these quartz-copper properties may successfully be concentrated at some future time, the ore or the concentrate being sold to a custom smelter. But there is no immediate prospect of this. There are also many gold prospects, some well worthy of examination, but only a few have produced gold even in a small way, the most important being Shakespeare Mine near Webbwood, and Long Lake Mine, about 15 miles south-west of Sudbury, both now closed down.

IX. THE PRE-CAMBRIAN NICKEL-COPPER AREA AT SUDBURY.

At about 160 miles due east from the "Soo," we come to the thriving town of Sudbury, which, at first a railway town, provided a name for the famous copper-nickel area. The three smelters treating these ores are all located within a few miles of the town. The first discovery of ore in this area was made in 1883, during the construction of the main line of the Canadian Pacific Railway.

The more conspicuous outcrops of ore in the district were soon discovered, and later geological work showed that they are all closely associated with an intrusive rock known as norite. The great body of this intrusive was found to be a boat-shaped laccolith, about 40 miles in length and 15 miles in width, its longer axis lying at about 20 degrees north of east, the bow pointing south-westerly. The laccolith, which is considered by geologists to be a Keweenawan eruptive, was found to vary in thickness from about 1½ to 4 miles, the lower contact generally resting on igneous rocks, and being more basic than the upper. The upper, or acid edge of the eruptive surrounds a basin enclosing strata, totalling nearly two miles in thickness, of pre-Cambrian sediments, laid down during the Animikie epoch. From the outer or basic edge there branch off a number of dykes or offsets of norite, cutting through the surrounding formations for distances up to 8 or 10 miles. The numerous ore-bodies of the district are of two general types—those at or near the lower contact of the laccolith known as contact deposits, and those found in or along the norite dykes known as off-set deposits. The ore-bodies vary from a few few thousands to many millions of tons. The largest has not been exhaustively explored, but has close upon 50 million tons of ore indicated by diamond drilling.

In the 40 years since the first discovery was made approximately 17 million tons of ore has been mined, and 1,500 million pounds of nickel and copper has been recovered by the smelters in the form of Bessemer matte produced for refining. Reserves of about 100 million tons of ore have been indicated by development and diamond drilling. There are almost certainly bodies of ore not yet discovered, and some of the mines are sure to produce large tonnages of ore below the depth to which drilling has reached. Very few have been drilled to a greater depth than 1,200 feet, and none deeper than 2,500 feet. The above estimate of reserves is therefore very conservative, and will probably be greatly exceeded when it becomes necessary to examine the district more exhaustively, a generation or so in the future.

Besides the nickel and copper contents, the ores contain minute quantities of the precious metals (gold and silver) and of the rare metals of the platinum group (platinum, palladium, rhodium, ruthenium and iridium), all of which are recovered by two of the three refining processes in use.

These mines have for years supplied 80 to 90 per cent. of the world's nickel, and, unless consumption increases to an unexpected extent, are capable of doing so for a long future. The district as a whole stands well up in the first rank of the world's great metalliferous areas.

Other nickeliferous areas have been found in the better known part of pre-Cambrian. The associated metals and the related intrusive rock are generally similar to those at Sudbury, though none of the newer areas can compare with Sudbury area in extent of ore. From a mine in one of them the Mond Nickel Company purchased about 50,000 tons of ore of good grade, and a considerable reserve remains. There is a very good possibility of future discovery of one or more nickeliferous areas in the pre-Cambrian, rivalling in importance the Sudbury district.

X. THE COBALT SILVER AREA.

North-east of Sudbury, about 80 or 85 miles, is the town of Cobalt, the chief centre of the now famous silver area, which, since its first discovery nearly twenty years ago, has produced a daily average of two short tons of silver for every working day, and during its maximum year reached very nearly 3½ tons per working day.

Dr. Miller, Provincial Geologist, soon found that the silver here is associated with an intrusive sill of diabase generally about 1,200 feet in thickness. The native silver and other valuable minerals are found in a network of cracks extending upward or downward from the sill, and sometimes in the diabase itself; but they generally fade out within a few hundred feet of the intrusive. Valuable quantities of cobalt and arsenic are recovered with the lower grade ores. Much of the ore is extremely rich, yielding many thousands of ounces of silver per ton. Many specimens of nearly pure silver have been obtained, varying in weight from a few hundred pounds to more than a ton.

Cobalt camp is by no means exhausted. Some reserves remain above the sill, though most of the silver produced to date has come from areas whence the sill has been eroded away. Recently the venture is being taken of sinking shafts through the sill and exploring the lower contact, with promising results. There is also a near-lying territory of considerable area, penetrated by the sill, known as "The Gillies' Timber Limit," which will probably produce silver in the near future.

South-east of Cobalt, about 15 miles, there is a second very rich occurrence of silver, similarly associated with a diabase sill, possibly a continuation of the sill at Cobalt, some of the intervening part having been eroded away. The first discovery of silver in this camp, in the township of South Lorrain, was made only a few years later than that at Cobalt, and a few million ounces were soon recovered. Recently after a considerable interval of little or no production, the camp has become extremely active, as a result of the discovery of the famous Wood's Vein or Fault, and of richly mineralised parallel and cross veins near or connected with it, the Wood's Vein, in particular, rivalling or surpassing in richness the most remarkable discoveries at Cobalt. There are important differences between the silver occurrences in this area and those at Cobalt, and now that these differences are coming to be better understood, South Lorrain promises to be of great importance.

North-west of Cobalt, about 60 miles, is a third silver camp, Gowganda, which produced, up to the end of 1922, practically as much silver as South Lorrain, and which has been making quiet but steady progress. Here again, silver is associated with a diabase intrusion, and I may add that one of our most experienced geologists, familiar with the conditions at all three camps, thinks very highly of this camp.

There have been discovered numerous other minor occurrences of silver within this general area, one, the Casey Cobalt, being about 15 miles north-east of the town of Cobalt. Many outcrops of intrusive diabase have been mapped in the general area, roughly 70 miles square, stretching north-westerly from a line joining the south-east corner of the Sudbury norite laccolith and the southern edge of the South Lorrain diabase sill. The Sudbury norite is probably a differentiation product from the same magmatic source as the diabase, both having been intruded in the Keweenawan epoch. Near Wahnapitae Lake, and generally along the south-west part of the area mentioned, discoveries have been made in which the gold values are more important than the silver. This large area of roughly 5,000 square miles, which, for convenience, I shall refer to as the Cobalt Area, is of great interest for future prospecting. The three chief silver camps in it, Cobalt, Gowganda and South Lorrain, have already produced (to the end of 1923) nearly 350 million ounces (12,000 short tons) of silver. Production in this area is certain of a long future.

About 400 miles in a westerly direction from Cobalt, not far from Fort William and Port Arthur, near Thunder Cape in Lake Superior, is Silver Islet. It is truly an islet, being so small and storm-swept that the Silver Islet Mine, which, after producing a few million ounces of silver, was closed down in 1884, was operated only with considerable difficulty. It is noteworthy as well as suggestive that this silver occurrence was related to a diabase sill somewhat similar to that at Cobalt. The copper ore of Michigan, mined in the Keweenaw Peninsula on the opposite side of Lake Superior, is also argentiferous. The lavas and intrusives of the Keweenawan epoch apparently were the origin of silver mineralisation over a very extended area in this part of the pre-Cambrian. Whether argentiferous formations once covered the great interval between Silver Islet and Cobalt, and have been eroded away in whole or in great part, is at least an interesting speculation, and one on which the geologist and the prospector may cast light in future.

XI. The Porcupine Gold Area.

Lying north and north-east of this large Cobalt Area, and practically continuous with it, is a tract 50 miles wide and 200 miles long, stretching 100 miles into each province from the interprovincial boundary between Ontario and Quebec, which will almost certainly eclipse in total value of production, though not in spectacular discoveries, the famous Cobalt area. This for convenience we shall refer to as the Porcupine Area, since, because of the great gold mines of the Porcupine Camp, this name has come to be very widely known. In many townships in the Ontario part of this tract of country, claims have been staked, and in some instances whole townships have been staked practically solid. Now that attention is turned to the Quebec side of the boundary a similar rush is being made into that province. There are literally thousands of mining claims in the area, on many scores of which valid discoveries have been made, yielding in many cases substantial assays in gold. As a great part of the area is silt-or drift-covered, the difficulty and cost of testing and selecting a claim or group of claims containing a workable deposit of gold are greatly increased. But the areas in the Cobalt, Porcupine and other known promising parts of the pre-Cambrian are large enough, and are sufficiently widely mineralised, to reduce the element of chance to a low ratio, and to make success a reasonable certainty, provided that the work of intensive prospecting is placed under absolutely honest, highly energetic, and thoroughly skilled and experienced technical direction, and provided further that this work of intensive search is widely, courageously and persistently carried on. Future discoveries in areas such as this will result from courage, energy and intelligence, rather than from luck. Porcupine is not a poor man's area, but it is pre-eminently one for enterprising men or groups of men with large means, who can afford a few losses while awaiting success, and who will best be served if they arrange that those whose intelligence and energy win the success are allowed reasonably to share in it.

It was in 1908, four years after the discovery of silver at Cobalt, that the earliest gold find in this Porcupine Area was made, though the first important discovery in Porcupine Camp proper, the outcrop of what is now the Dome Mine, occurred in the following year. Production began in 1911. In spite of the devastating fire of that year and the difficulties of operation resulting from the great war, which have caused a heavy shrinkage in gold production in every other part of the world, the output of gold has steadily increased in this area. The value of the gold production in the Porcupine Area, in the 12 or 13 years of gold mining prior to 1924, exceeded 125 million dollars. One mine, the Hollinger produced a daily average of more than 1,600 ounces during 1922, and has stood third in the list of the world's greatest gold producers for two years. It is expected that its production will be practically doubled as soon as its new hydro-electric plant, now in course of construction, is completed. This mine has already produced gold worth more than 70 million dollars and has a rapidly increasing reserve of ore, containing at the end of 1923 about 80 per cent. as much more gold. It is said to produce gold at the rate of 150,000 dollars per vertical foot.

The mines so far developed in this area are showing every indication of persistent mineralisation with depth. Geologists have expressed the opinion that the limiting features as the mines deepen are likely to be due to mechanical difficulties, or possibly to increasing rock pressure, rather than to the failure of the ore-bodies. Rise in temperature with increasing depth in the pre-Cambrian is not a serious factor, as shown in the deepest Michigan copper mines, and in one mine of 3,000 feet depth in Sudbury district. The deepest of the mines in operation, now developing ore between 2,000 and 2,500 feet from surface, is the McIntyre, whose ore-bodies have steadily improved in number and size with increasing depth. None of the mines has shown any tendency to become impoverished in gold values as deeper levels are developed.

The principal mines at present in operation in the larger Porcupine area are in two groups located respectively at or near the town of Timmins, the original Porcupine area, and at Kirkland Lake. But the area of actual operation is extending, and there will probably be many more producing mines within the general tract of roughly 10,000 square miles already indicated. Already a dozen mines are producing gold, and it is almost certain that within three or four years this number will reach, and may exceed a score. No one at present can safely hazard a guess as to the ultimate future of the greater Porcupine area, but the probabilities of the area are very great, and its possibilities are literally enormous.

XII. Some Notes on Geology.

Dr. Miller, I believe, regards the auriferous veins as genetically related to the Algoman granite. Dr. Coleman and Dr. Parks, in their text-book on "Elementary Geology," refer to this opinion, apparently with approval. The recognition of the Algoman granite as the origin of the gold in this area seems to be of the greatest importance in the economic interpretation of the pre-Cambrian as a whole. For, to the prospector and the mining engineer, the large areas of granite and gneiss in the pre-Cambrian have, heretofore, been anathema. This discovery is indeed of profound significance, and may revolutionise economic views of large areas of the pre-Cambrian. Up to the present there are very few localities where the Laurentian and the Algoman granites have been separated. It must, indeed, be extremely difficult in most cases to separate them. Yet, if the gold in the Porcupine area is derived from the Algoman granite, and is associated with derivatives (residual quartz veins, dikes, etc.) from this granite, the importance of this discovery and of making the separation between the two granites as rapidly as possible, can hardly be overestimated.

We may at this point profitably digress long enough to catch a glimpse of this later geological view, which, as we have seen, is of much significance in our present discussion. To summarise, my understanding of this view in as few words as possible, the outstanding geological events of the pre-Cambrian may be sketched as follows: Just as an invasion of granites and gneisses on a vast scale, extending over a great period of time known as the Laurentian epoch, gradually lifted and distorted the sedimentaries and lavas of the preceding Grenville and Keewatin series, forming stupendous mountains; and just as the Laurentian epoch of mountain building was followed by another enormous period of time, during which these mountains were eroded to base level and gradually sank beneath the sea, so as to receive the offshore sedimentary deposits of the succeeding epoch; so were the sedimentaries of this succeeding Sudburian or Timiskamian series tilted, folded, and elevated in their turn by a new invasion of granites and gneisses, during a second great period of mountain building known as the Algoman epoch; and so also was this second or Algoman epoch of mountain building succeeded by another vast interval of time, the longest break in Canadian pre-Cambrian geological history, during which the Algoman mountains were also in their turn eroded away to a new base level or peneplain, which received, beginning at or near its southern edge, the sediments, including glacial materials, of the Huronian series. To complete the outline of the epochs of the pre-Cambrian, we may add that the Huronian epoch was followed by a great sinking of the Canadian Shield beneath the sea, during which the materials of the Animikie series were deposited on the sea-floor; and that this epoch, after a considerable break, was followed by an enormous outpouring of lava, accompanied by many related intrusives—dykes, laccoliths and sills—which furnished most of the materials of the Keweenawan series, during an epoch which in this respect was very similar to the Keewatin epoch at the beginning of pre-Cambrian times. Thus the opening and closing epochs of the pre-Cambrian in Canada were characterised by intense vulcanism with enormous outpourings of lava over large areas of the Shield. The vast amount of time that must have been required for all of these geological changes may easily have been many hundreds of millions of years—may, in fact, greatly exceed in total time the eons that have elapsed between the beginning of the succeeding Cambrian period and the present, comprising the whole of the Palaeozoic, Mesozoic and Cainozoic eras.

Though the geologists of our Dominion and Provincial Departments and of our universities have expressed some of these views, and have adopted some of this terminology, somewhat tentatively, it would scarcely be possible to speak too highly of the way in which they are gradually disentangling the geological history of this vast area, which for a long period appeared to be so hopeless that most of its formations were merely lumped together and cast on one side under the title "basement complex," a label almost of despair. In fact, the term pre-Cambrian itself, which we have used so freely, is a relic of this period of despair, and, I believe, must sooner or later be replaced by one or more terms having a more positive meaning.

To our Canadian geologists must also be given the credit for furnishing a scientific foundation for the work of the prospector, the examiner of mineral claims in detail, and the engineer engaged in the actual work of mining. No one now thinks for a moment of proceeding with these classes of work without the assistance of geological maps. Indeed, much of the work of both general and intensive prospecting is now carried on under the direction and supervision of men who were trained in geology in the universities, and in field-work in the Government geological surveys. As may easily be inferred from the previous discussion, these classes of geological work have a great future before them in the pre-Cambrian of Canada. But this work must not be allowed to interfere with the fundamental scientific work of the geological surveys of the national and provincial Governments, the importance of which can hardly be over-estimated. These departments are not less important as a training school in field geology than for the guidance they furnish to the mining industry.

XIII. Wide Occurrence of Gold in the Southern Pre-Cambrian.

To return from this brief digression on geology: Though gold was discovered in the pre-Cambrian and mined in a small way more than 50 years ago, no marked success in gold mining in this vast area was attained before the first Porcupine discovery. But it is very noteworthy that gold discoveries have been made in most of the series of rocks enumerated, in at least two score localities, widely distributed from the extreme south-eastern limit of the pre-Cambrian in Ontario to the western boundary of the province, and on into Manitoba—a distance of more than 1,000 miles—and at intervals over a wide belt. Since this is nearly all of the pre-Cambrian that has been even run over by prospectors (we can certainly not grant that, except in a few small areas, it has been really prospected), the prospector in any part of the pre-Cambrian would be acting wisely to be always on the look-out for gold. It is more than possible that, with the successful experience in the Porcupine Area back of us, a number of these old and new discoveries beyond the limits of this area may be brought into successful production.

XIV. A Prediction.

Considering all the facts briefly outlined, it would seem possible that the vast pre-Cambrian area may in time become the greatest and most permanent single source of supply of the world's needs in the precious metals. This is not said without due recognition of the great lead in gold production at present to the credit of South Africa. Whatever opinion may be held as to this possibility, it is now practically certain that the pre-Cambrian in Canada will produce vast wealth in gold and silver. The immense possibilities of the pre-

Cambrian in the production of mineral wealth have been, and probably will continue to be, revealed but slowly; partly because of the very great geological complexities referred to; partly because of the costly, though indispensable, work of intensive search for valuable deposits of ore, made necessary by the removal of conspicuous outcrops through glaciation, and by the partial concealment of the surface caused by the widespread mantle of drift left on the retreat of the ice-sheet; partly because of climate, which, though not unendurable, is severe in winter; and partly because, over a large percentage of the area, transportation will be a very difficult problem, the facilities adopted for transportation having few, if any, other supporting industries than mining, though much of the area is within moderate distance of navigable water. But mining men have ever shown remarkable enterprise in overcoming obstacles to transportation, such as would be regarded as insuperable in any other business: witness the transportation improvised to Klondike and to Keno Hill in Yukon Territory, and that now planned to Katanga. A railway in successful operation to Hudson Bay will give access to great areas of the pre-Cambrian.

XV. IRON ORE IN THE CANADIAN PRE-CAMBRIAN.

Let us next consider briefly the iron ore resources of the Canadian Shield. We have already glanced at the great iron ore reserves in the Lake Superior region of the United States, and have noted the enormous industrial development in the area lying north of the Ohio River and east of the Mississippi —an unparalleled economic expansion, the key to which is to be found in the deposits of iron ore in that relatively small corner of the pre-Cambrian. We have noted, too, that, though the reserves of ore of suitable grade for direct smelting are still very large, the rate of consumption is also very great—so great in fact that, assuming normal rate of increase, the blast furnaces dependent on them will probably begin to feel the pinch within 25 years; but that already the technical problem of improving the lower grade ores is being vigorously attacked on a large scale.

Now, these iron formations south and west of Lake Superior extend into Canada both at the west end of the lake and across it. Geologists of the United States Geological Survey, familiar with the deposits similar to these on their side of the boundary, on the basis of such evidence as was available, estimated the iron ore in Canada tributary to Lake Superior at 9,000 million tons, having an iron content of 35 per cent. or higher. This did not include the large reserves of ore known at Moose Mountain and in Michipicoten District. Further extensive discoveries of iron ore have been made since this rough estimate was given out, and iron ore of similar grade is known to exist at many other points in the pre-Cambrian, some of these being on islands and on the mainland along the eastern coast of Hudson Bay. The iron ore here is reported to occur in the same formations and under similar conditions to the deposits in the famous Lake Superior region in the United States, and it is believed that search with the diamond drill will reveal rich ores suitable for direct smelting, as proved to be true in the pre-Cambrian ores in United States.

It is more than possible, it is, I believe, probable, that extensive exploration of other large Canadian deposits with the diamond drill may yet prove bodies of ore of suitable grade for direct smelting. Iron ore of direct smelting grade was formerly produced for some years at Helen Mine in Michipicoten District, in Ontario. Failing this, at any rate until the richer ores in Minnesota and Michigan are more nearly exhausted, it can hardly be expected that these lower grade ores will compete successfully with those of higher grade in the United States. As a matter of public policy, the present provincial Government of Ontario has under consideration the provision of a bounty to meet the competitive handicap. In considering the mineral resources of the pre-Cambrian, we are, in any case, safe in assuming that of lower grade iron ores, requiring beneficiating, there are practically inexhaustible reserves; also, that there are good possibilities that supplies of better grade ores may yet be found as prospecting and further exploration of the bodies of ore already discovered are continued.

XVI. NON-METALLIC MINERALS IN THE PRE-CAMBRIAN.

It would be interesting, if we had the time, to discuss the occurrence of non-metallic economic minerals in the pre-Cambrian. There is a long list of these, some of which occur in great abundance, and seem likely to become of growing importance as our population increases. Among them are feldspar, graphite, mica, talc, ceramic and other clays, apatite, corundum, magnesite, and molybdenite, as well as building and ornamental stone. The deposits of these humbler minerals will prove to be a very large asset as the pre-Cambrian area becomes more fully developed.

XVII. DIRECT AND INFERENTIAL EVIDENCE REGARDING THE REMOTE PARTS OF THE PRE-CAMBRIAN.

We have now sketched in broad outline the more important actual achievements in mineral discovery and production in the pre-Cambrian Shield of North America, nearly the whole of which is in Canada. We have noted, as we proceeded, a number of very significant geological facts, having important bearings on various mineral occurrences. We are nearing the point at which reason must be applied to the facts presented, in order to estimate their wider significance.

Before doing so, however, there are two other lines of evidence, which, though not as complete as we could wish, must nevertheless be adduced and carefully weighed in our effort to interpret the pre-Cambrian as a whole. These lines of evidence may be elicited by seeking answers to the two inquiries: (1) What evidence, if any, have we that the remainder of the pre-Cambrian is composed of geological formations similar to those in the area with which we are most familar ? and (2) What evidence is there that these outlying parts are similarly mineralised ?

(1) THE GEOLOGICAL FORMATIONS.—The great northern, north-eastern and north-western parts of the pre-Cambrian are geologically but little known. They have been remote and difficult of access; and the seasons suitable for field work are comparatively short. The aeroplane will be of assistance in future study of some parts of these remote areas. A vast amount of geological work remains to be done even in the southern area, which is easily accessible from the Great Lakes, the St. Lawrence River, and the existing railways. The great complexity of the geological problems, which sometimes prove very baffling, has already been commented on. The few geological explorers who have penetrated to these remoter regions, because of these conditions have as a rule been compelled to stick closely to canoe routes. This has generally reduced their reports to accounts of observations along widely separated routes of exploration, under such limitations that only very tentative conclusions as to age relationships of observed rock formations could be reached.

Because of general preponderance of granites and gneisses, which until quite recently were wholly undifferentiated as to age, and are still lumped together as Laurentian (just as most of the pre-Cambrian was formerly labelled " basement complex ") vast areas between these routes of exploration are shown on the maps in the same colour as the Laurentian proper. Hence, other formations, shown distinctively on the maps, may generally be considered as having actually been observed; whereas much of the area shown in the conventional colour as Laurentian is, as indicated by the map legends, the significance of which is frequently not fully appreciated, " Laurentian and Undivided pre-Cambrian." The total of the larger areas lying between the travelled routes of explorers, some of them being great blocks of more than 50,000 square miles, which have never been observed even hurriedly by any geologist, amounts to a very large part, probably much more than half, of the entire pre-Cambrian. It is very noteworthy that, as the work of geological mapping proceeds, the apparent Laurentian formation shrinks in area, and the total of the other pre-Cambrian series, which, in general, have so far proved to be more richly mineralised, grows in relative area. Examination of the latest geological maps of Canada shows, in all three of these remoter regions, several large areas of Keweenawan, Animikie, and other series, already noted by the exploring geologists, frequently under local names, the correlation still being doubtful, with wide areas as stated, shown as " Laurentian and Undivided pre-Cambrian," beyond the routes travelled. Even in the Arctic Islands, with a surface exceeding 500,000 square miles, of which the exposed pre-Cambrian may occupy as much as half, though insufficient geological work has been done to determine the succession of the pre-Cambrian formations, geological exploration has yet been sufficient to reveal a great variety of formations similar to those found in Ontario and Southern Quebec. At the recent meeting of the Canadian Institute of Mining and Metallurgy, Dr. Miller, an eminent authority on pre-Cambrian geology, stated that undoubted Laurentian granite in place is hard to find.

It is, therefore, a natural—and, I think you will agree, warrantable—inference that, as exploring and geological mapping continue, the more highly mineralised pre-Cambrian series noted previously in this discussion will be found, if we compare wide areas and broad averages, in roughly similar proportions to those mapped in the better known parts of Quebec, Ontario and Manitoba. This better known area is the southern part of the pre-Cambrian, to which the St. Lawrence River, the Great Lakes, and the transcontinental railways afford reasonably easy access. It comprises rather less than one-eighth of the entire Canadian Shield, or, roughly, 225,000 square miles. But even of this small fraction of the pre-Cambrian very little has been geologically mapped in any detail, except at and near important discoveries.

(2) THE MINERALISATION.— The answer to the second inquiry is even more difficult to obtain, and to weigh properly, than the answer to the first; since, obviously, valuable minerals are not as easily discovered as large areas of differing rock formations, in fact are almost never discovered even in detailed geological examination, much less in rapid exploratory work; and since, equally obviously, no serious prospecting on any extended scale, and no serious development of mineral deposits, have been carried out in these at present remote regions, or are likely to be for many years to come. This delay in developing the remoter areas of the pre-Cambrian is all the more probable, because of the great mineral riches, both proven and indicated, which we have noted in the areas more easily accessible at present.

Nevertheless, from the standpoint of wider public policy, it becomes important to use our best judgment and reasoning powers in an effort to forecast the economic future of these great areas as accurately as is at present possible. Canada's present economic unbalance; her widely scattered and sectionalised population; her failure to develop the country beyond the limits of a narrow fringe contiguous to the United States, a fringe that is becoming more and more economically penetrated by the wealthy and enterprising citizens of her consanguineous neighbour; her strong tendency to follow easy lines of imitation in place of striking out boldly on lines of independent policy, based on her own peculiar resources; her consequent tendency to become imitative rather than robustly independent, in the development of her national life; in a word, her habit of looking southward rather than northward for economic opportunity; and the lessening of her independence which results from this habit; these are some of the undesirable results attributable in great part to the failure of Canadians to understand the economic significance of more than half their own country, and of their consequent failure to teach their children, both at home and at school, the economic possibilities of the greater part of their own country, rather than those of the United States.

Let us then further pursue the inquiry regarding the mineral resources of the remoter parts of the pre-Cambrian. This must admittedly be based chiefly on inference. There is, however, a certain amount of positive evidence of much inferential significance.

In the Arctic islands there has naturally been none of the close intensive work of the prospector, so necessary to discovery of valuable minerals in the pre-Cambrian, though geological formations occur similar to those which have been most productive in the United States and Southern Canada. The islands are remarkably free from permanent ice caps, considering their high latitude. The rocks are well exposed in summer. Mica is known to occur at several points in the Grenville formations at the south of Baffin Island, and has been actively mined at Lake Harbour. Graphite has also been mined. Specimens of other valuable minerals have been found. These facts, though comparatively unimportant in themselves, are highly significant as indicating the probability that formations in this northern region similar to those farther south will be similarly mineral-bearing. Sudbury, Cobalt and Porcupine fifty years ago had less prospective value than these formations now possess, since Canadians had before that time had but little reason for thinking that any part of the Canadian Shield would produce minerals of any serious value.

In the great Labrador peninsula, which was added to the Province of Quebec a few years ago, geological exploration has made but little progress in the interior. Iron ore has been reported by Dr. Low to occur on islands, as well as on the mainland along the east coast of Hudson Bay, under similar geological conditions to the occurrences south and west of Lake Superior. The occurrence of other economic minerals near the same coast is also known. Dr. Low also reports the occurrence of iron ore at the west of Ungava Bay. Dr. Coleman, who made a study of the geology of the north-east coast of Labrador in 1915 and 1916, after referring to the fact that no prospecting has been done, and pointing out that rocks resembling the productive series in Ontario and Quebec cover large areas, ends his memoir with these significant statements: "So far as can be seen the conditions are similar to those which have caused the economic deposits of the Grenville, Timiskaming, Huronian, Animikie, and Keweenawan series of Ontario and Quebec; deposits which have made Ontario one of the great mining regions of the world.

"It is evident that the almost unknown interior of Labrador includes not alone barren granite gneisses, as commonly supposed, but probably also equal areas of other pre-Cambrian rocks of much greater economic promise. It is a region that deserves closer study than it has yet received, and its very bareness and lack of vegetation facilitate such an examination, as compared with regions largely hidden under drift or covered with forest."

In the great north-western area of the pre-Cambrian a little more of the fringes is known. The railway which was begun, some years ago, to connect the Prairie Provinces with Hudson Bay made the so called "Pas Mineral District" on the southern fringe in Manitoba more accessible. This increased accessibility was quickly followed by the discovery and diamond drilling of the Flin Flon and Mandy ore-bodies. The former was proven by drilling to have at least 16 million tons of ore above 900 feet depth, and one or more holes proved the continuance of the ore to 1,800 feet depth. The recoverable copper in this ore probably exceeds 500 million pounds. Mandy Mine was found by drilling to contain a smaller body of very rich ore—25,000 tons averaging about 20% copper, and 180,000 tons running 5 to 8% copper and 20 to 30% zinc, both grades of ore averaging about $5 per ton in gold and silver. Discoveries of a considerable number of gold veins were also made in the same general area at Elbow Lake, Herb Lake, and some other points. Several of these, in spite of the severe handicap of lack of transportation, are being developed, and are reported to be of considerable promise.

Northward from this lies a vast area of pre-Cambrian formations, totalling more than 500,000 square miles, about the geology and minerals of which very little is known, if we except slight knowledge of areas near the large marginal glacial lakes, near the shore of Hudson Bay and along a few routes followed by explorers. Along the west coast of Hudson Bay Mr. J. B. Tyrell noted a large area of Huronian formation, in which he found extensive copper mineralisation. But in the extreme north, the region near Coronation Gulf has been more accessible than the interior, both by way of Behring St. and the Arctic Ocean, and by way of Mackenzie River and Great Bear Lake. Here, south-westerly from the Gulf' south-easterly along Bathurst Inlet, and easterly from it, as well as on many small islands in these waters, are large areas of Keweenawan lava, similar to the copper-bearing eruptives of Keweenaw Point in Michigan, which, as we have noted, have made that peninsula one of the most productive copper regions known. The Eskimos have for many years satisfied their small requirements for metal by visiting annually Copper Mountain on the Coppermine River, a mountain near Prince Albert Sound on Victoria Island, and some other points, where they picked up small supplies of native copper. Several exploring parties have proven the existence of copper over extensive areas, under similar geological conditions to those in Michigan. It is not possible in this paper, and it would in any case be a digression from our main theme, to review the discussions that have been printed regarding the possible economic value of these deposits within any near future. It is worth noting that coal is known to occur in some of the Arctic Islands, notably on Banks, Melville and Bathurst Islands. Toward the close of the Great War the Federal Government, on the advice of its technical experts, considered the mineral area near Coronation Gulf of sufficient importance to withdraw from staking this area and the territory to the northward.

Now, is it not remarkable as well as highly significant, that, again, where reasonable access has made examination possible, the formations have been observed to be similar, and similarly mineralised, to those found near the extreme southern rim of the pre-Cambrian? Those who know the pre-Cambrian best, from long first-hand experience in it, may feel that this question would have more point if reversed, thus: Would it not be even more remarkable had examination shown that this region differs from the better known parts of similar formation in the pre-Cambrian, in not being similarly mineralised? In any case this occurrence, at a distance of 1,500 miles from that in Keweenaw Peninsula, Michigan, must add greatly to the sense of uniformity in the pre-Cambrian for those not thus experienced. A clear conception of the immense scale on which the major events occurred in pre-Cambrian geological history will add greatly to the attentive student's growing sense of broad uniformity over the whole of this immense area. But the caution, of regarding only broad averages in interpretation, must be repeated.

XVII. General Conclusion regarding Mineral Wealth of the Pre-Cambrian.

Now, let us stand off far enough to view broadly, and to see in proper mental perspective, the great facts and principles we have considered, so as to grasp clearly their wider significance. To summarise: We have made an effort to comprehend the vastness of the pre-Cambrian Shield in Canada, with its area of 2,000,000 square miles, occupying well over one-half the surface of the country. We have noted briefly the enormously long geological history revealed by its rock formations, probably extending to greater length than all subsequent geological time. We have glanced at its vast epochs of mountain-building, each followed by a great period of geological degradation and later sedimentation. We have seen that these immense geological cycles were on so great a scale that the Shield, though of such extended area, was practically a unit in relation to the profound effects of the long continued action of these geological agencies and forces. We have observed, finally, that nearly all traces of geological history throughout Palaeozoic, Mesozoic, and Cainozoic time over this great area have been swept away; that only a few tens of thousands of years have elapsed since there retreated from almost the entire area an enormous glacial ice-sheet, which had covered nearly the whole northern half of the continent for a very long stretch of time, with some inter-glacial periods, each of which is thought by Dr. Coleman to be of greater length than the entire period since the final retreat; and that during this glacial period the accumulated residual débris of ages of ordinary erosion was swept away, the present topography of the area was completed, and the pre-Cambrian formations were left exposed, except for a relatively slight mantle of drift over parts of the area, making possible a study in detail of geological history and structure, and discovery of mineral resources, over an area equalled nowhere else.

We also briefly reviewed the achievements in mining and in proving reserves of mineral wealth in the southern fringe of the pre-Cambrian, in the Lake Superior Iron Mines, the Michigan Copper Mines, the Sudbury Nickel-Copper Mines, the Cobalt Area Silver Mines, and the Porcupine Area Gold Mines, and noted the great future probabilities in each instance. We might further summarise the achievements in mining by saying that these five great areas have already produced mineral wealth which, in its crude forms of iron or steel, copper, nickel, gold and silver, as these metals left the hands of the metallurgists, had a gross value of not far from 15 billions of dollars. But even more important is the fact that these mineral products became generally the raw materials of a great number of manufacturing plants from which they issued with a value of some scores of billions of dollars. They thus became the material foundation of a large part of the capital wealth, and of the civilised life of much of the continent of North America, illustrating incidentally the truth of the generalisation that mining is the basic industry of civilised progress on its material side, as agriculture is of subsistence. We might add that the known mineral wealth remaining in these five important areas is certainly several, and probably many, times the mineral wealth already produced.

We next noted that, in addition to the probability of broad uniformity of general geological formations, as would be suspected by inference, this broad uniformity over the Shield is reasonably confirmed by observation, as far as geological exploration has extended. We noted, too, that the inferential suspicion that similar mineralisation would broadly follow similar geological conditions because of the wide geological uniformity proven to exist, is confirmed to as great an extent as could at present be expected, in view of the entire lack of intensive prospecting in the remoter regions —a method of search that has been found indispensable in the regions best known.

Are we not, then, justified in taking the next inferential step? Canadians have centuries of geological work and detailed prospecting ahead in the pre-Cambrian. Are these arduous and costly classes of work of sufficient promise to warrant their being energetically, persistently and widely carried on? Over an area so vast, and broadly so uniform, in rock formations and mineralisation, is it not a reasonable certainty that the achievements of the past, both in discovery and in recovery of minerals in but a few per cent. of the total area will be repeated over and over again in the great pre-Cambrian area as a whole? It would naturally be folly to predict how many times the value of the mineral wealth already discovered and recovered will be repeated. But that it will be repeated again and again no man who grasps the facts and who trusts his reason will deny.

During the first few years of my engagement in mining in the pre-Cambrian area I had serious doubts as to its mineral possibilities. Gradually the greatness of its mineral wealth became a probability. I have now had twenty years' experience in the area, during which period I have tried, by as wide observation and study as possible, to comprehend the economic significance of the pre-Cambrian, and have become fully convinced of the truth of the inference stated regarding its vast mineral wealth.

DISCUSSION.

The Chairman (Sir Richard Redmayne) said they owed a debt of gratitude to Dr. Corless for the very admirable address which he had delivered. He (the Chairman) would have liked a week or two in which to study the paper thoroughly before commenting on it. It was bristling with matter of interest. It appealed not only to the practical man, the prospector, the geologist, the man of business, but to the pure scientific geologist also. As to the lecturer's explanation of the outstanding geological events of the pre-Cambrian, he had marked half a column of that portion of the paper, which was most fascinating and most interesting reading; but when the lecturer came to the conclusion of the explanation of the pre-Cambrian formation, he was left gasping, like a fish that had recently been pulled out of water, for Dr. Corless required, not a million or a few millions of years, but millions and millions of years for the carrying out of the geological processes which had left the pre-Cambrian in the state it now was. He had not the slightest doubt that Dr. Corless was right, but he (Sir Richard Redmayne) would like, some time, to debate that question. What appealed to practical people was this point: what evidence was there that these outlying parts were similarly mineralised? That was a matter of the very highest importance, and the reasons that Dr. Corless had given for his belief that they were, were of very far-reaching interest. The pre-Cambrian (which in his youth he was taught to call the Laurentian, named after the St. Lawrence River) in other parts of the world had certainly been very fruitful of great mineral wealth —platinum, silver, gold, cobalt, nickel and plumbago. As to the plumbago of Ceylon and the great banket deposits of South Africa, it was agreed among the most eminent geologists that these as well as the goldfields of Western Australia were of pre-Cambrian origin. The greatest source of gold at the present time was formed by the banket deposits of the Rand. Looking to the future, he thought there was little doubt from the indications which were forthcoming, and from what Dr. Corless had said, that the centre of gravity, so far as the gold production of the world was concerned, would shift, not slowly but rapidly, to Canada. Anybody who had given time to the study of the Porcupine deposits must come to the conclusion that their possibilities were immense. Before he sat down he would like to try and point the moral. In Canada they had all this enormous mineral wealth; but what were they, in Great Britain, doing to assist in its development? The United States of America was doing a very great deal, but surely Britain ought to have a hand in it. He believed it was a fact that only some 2.8 per cent. of the capital invested in gold mining in Canada was purely British. That did not seem right. He hoped and believed that Dr. Corless's paper would be read broadcast. He was glad Dr. Corless had chosen the Royal Society of Arts for his starting-off ground, because in that way the paper would receive very wide circulation and very wide consideration by the best possible type of mind. There was one thing he would ask. Towards the end of the paper, Dr. Corless had said: "It is worth noting that coal is known to occur in some of the Arctic Islands, notably on Banks, Melville and Bathurst Islands." He did not suppose Dr. Corless meant by that that it occurred in the pre-Cambrian.

Dr. Corless: No.

The Chairman said he thought not, but he wanted to be sure of that, because otherwise it would upset the whole of his ideas as to the formation of coal.

Sir Thomas Holland, K.C.S.I., K.C.I.E., LL.D., F.R.S., said he would make his remarks as brief as possible for two excellent reasons. One was that there were so many distinguished Canadians present that one wondered how the business of the Dominion was being carried on during that month!

The other, and more important one for him, was that he was shortly going to visit Canada, and the remarks he would make that afternoon were bound to be tinged with the out-of-date impression left upon him after his last visit, in 1913. The less he said that day the less he would have to answer for when he got across to Toronto next month. There was one feature of Dr. Corless's paper which struck him as being of extreme interest, and that was where he referred to the discrimination between the Algoman series of granites and the old Laurentian granites. In the old days they used to look upon all the great granitic or gneissose series in the Archaean part of the pre-Cambrian as being roughly of about the same type. They varied locally, and they gave a certain amount of amusement to the microscopic petrologist, but generally they were treated as of the same great family. So long as that idea existed prospecting through these Archaean areas was a matter of chance, and a very small chance, too. A needle was a very prominent article in a haystack compared with gold deposits on the enormous stretches of Archaean which existed on the world's surface. The Canadian geologists had gone a very big step forward in showing them that there was a fundamental difference between the old Laurentian granites and those which they had distinguished as Algomans. He would not say the Algoman granite brought the gold in, but the intrusion of the Algoman granite gave rise to that form of rejuvenation of the old Archaean lines which resulted in the concentration of gold deposits like that of the Porcupine and similar areas. In the same way they had connected the diabase intrusions of Keweenawan age with the silver deposits of Cobalt and the nickel-copper ores of Sudbury. These particular forms of discrimination had enabled prospectors to confine their operations to certain areas, and, secondly, to look hopefully and intelligently at those areas where there were geological features of the kind indicated as promising. Still, there was room for further discrimination in a narrower circle. It was all very fine to say that the great areas of pre-Cambrian Canada gave such brilliant results as Porcupine, Cobalt, and Sudbury. But there were still enormous areas that were pre-Cambrian, and even areas that contained Algoman granites which were not Porcupines, not Sudburys and not Cobalts. It was just there that the precise discrimination by the geologist became necessary. A great deal of harm was done in the old days by the assumption that the great Archaean areas must necessarily be barren because most of the ground covered and accessible was found to be barren. A good deal of harm was done after the discovery of some promising places in jumping to the conclusion that they were going to have any number of South Africas and any number of Porcupines in other parts of the pre-Cambrian shield in Canada. That harm would not be permanent so long as the facts dealt with were sifted by men who, like Dr. Mackintosh Bell, Dr. Corless, Dr. Miller, Dr. Brock, and others he might mention, had superseded the old rule of thumb of prospecting work in Canada, and turned it into real science, showing that the discrimination they made was not a crude discrimination, but one which enabled them to say definitely they did not assume that because they had Algoman granites they were going to have Porcupines. One had only to take the case of the Keeley mine as an instance of remarkable discrimination. The old Keeley mine, which broke one of the big banks of Toronto, and was the cause of getting the manager into trouble because of his confidence in it, was taken over for a small sum of £20,000. After the work of Dr. Mackintosh Bell, who merely set the operations going a short distance away from the place where they had been worked before, the Keeley mine had since produced enormous quantities of silver. The great value of the work which had been done by Canadian geologists was in discriminating between pre-Cambrian that was of no use and pre-Cambrian that was hopeful, and between pre-Cambrian that was hopeful and pre-Cambrian that was valuable. Nothing was more admirable than the discrimination and care which the Canadian geologists had shown in examining the residue which was hopeful. He was perfectly sure that the impression that had been left in England, alternately too hopeful and too depressing, would be removed in a very healthy way by papers of the kind that Dr. Corless had read. Possibly, after the members of the Society, numbering 3,500, had read the paper they would begin to forget what they did with the money which they put into Grand Trunk debentures.

Dr. W. G. Miller, F.R.S.C., F.G.S. (Canada), said that Dr. Corless had been doing considerable missionary work in Canada in connexion with the pre-Cambrian. The ordinary man in the street had not heard much about it until Dr. Corless began to give some addresses on the subject a few years ago. The population was getting greatly stirred up. A short time before he left Toronto a representative of a Board of Trade came to see him, stating that he had been importuned to get out a pamphlet on the pre-Cambrian, and he wanted to find out what it was. Apparently, he did not know whether it was an animal or a vegetable! They had had very many discussions on the pre-Cambrian in Canada, but it had never been discussed under the conditions under which they were discussing it then. One never had a Gainsborough or a Reynolds looking down on him during the discussion of the subject. There were two or three points in Dr. Corless's paper which he would like to refer to briefly. Dr. Corless made an interesting reference to certain historical occurrences, and he had often thought what would have happened in connexion with the political status of North America if the Cobalt silver area had been discovered during the French period. That area had produced roughly 350,000,000 ounces of silver, which would have been worth in those days nominally £100,000,000; £100,000,000 in those days would be worth about one billion pounds in these times. Those fields could have been worked just as easily in the French period as they were worked to-day, because they were near the great Ottawa River. The French could have taken out much of that silver. If that area had been discovered in those days what would have happened? The French probably would have come over in such great numbers that they would have held Canada. If they had not succeeded in holding it the colonists would have taken it over, and then, when the Revolution of 1776 came along, it would have become part of the United States of America. Discoveries were made along the Ottawa River long before, in the 17th century. One of the oldest known ore deposits in North America was in the Lake Timiskaming extension of the Ottawa River, nine miles from Cobalt. The early explorers went up in birch bark canoes. That was, no doubt, the earliest thing the explorers found. The Cobalt area escaped till a more opportune time, and the whole of the pre-Cambrian had been held up. However, they had so many debts to pay that it was just as well that development had been delayed, and in that sense, perhaps, there was the hand of Providence in it.

Dr. D. B. Dowling (Canada) thought he might give his conception of the history of the pre-Cambrian in this way. Since he had been in London he had seen objects of art, architecture, and other things which carried the mind back in time to very remote ages. Part of those things were dated definitely. There were pictures painted in a certain year; there were houses built in a certain year. One went to the British Museum and saw certain things which were older, and then one lost the scheme of dates. Such a thing was "about the 3rd century," or "about the 10th century," or "between the 11th and 12th century," etc.; so in modern history they had a different set of scales. For recent times the scale was definite, but, as they went back, the scale became a little more indefinite, and one had then to adopt a new method of adjustment to see how old the thing was. Exactly the same thing happened in geological history. One could say almost definitely the age of certain rocks by the history of the neoliths found in those rocks; but then they came to a series of rocks in which the method of estimating time was by a different scale. Could they not compare these two things? Modern history was very definite—back to the Christian era, to the first century. Beyond that one could go back till one ended with Adam, but it was not definite. It was the same thing in the pre-Cambrian. They came to the time when they could historically estimate the lapse of time in regard to the rocks. When they went back to the time of the first crust of the earth, listening to Dr. Corless and the other geologists who were working on that area, they found there was probably not any one original crust of the earth; in other words, the earth in that very remote period passed through several stages. There were crusts at different times, and it was in those crusts that these metalliferous deposits had been deposited. The next important subject of study in their old history was to trace the different ages and to find in the rocks the different minerals which belonged to each, because he had some idea that the older ones had different metals from the newer ones.

Dr. J. W. Evans, C.B.E., F.R.S., said that the one thing which had struck him with regard to the valuable mineral deposits in the pre-Cambrian of Canada was the accidental way in which they were originally discovered. The copper deposits of Sudbury, which afterwards became very valuable for their nickel, were discovered in the course of making the Canadian Pacific Railway. The silver, cobalt, and nickel deposits at Cobalt were found in the same way. The glacier ice sheet had done a great deal in clearing away the decomposition products from the surface of the earth, but it had not entirely done it. As a general rule, one must not expect to find valuable minerals in the whalebacks or whale-shaped masses of rocks which were so characteristic of that country. As one travelled through the country one saw these great surfaces of rocks and one might think that prospecting for minerals would therefore be very easy; but one must remember the glaciers, as they passed across the country, had carried away the soft material, and these whalebacks represented the hard barren material where one could not expect to find anything. But when they came to make a railway, which followed the low ground where there had been erosion, they found mineral deposits which could never have been discovered by examining whalebacks. The possibilities arising from this great mass of pre-Cambrian rocks were far vaster than had been supposed. They were covered and hidden, if not by decomposition products, by vegetation. The problem was how to come upon the ancient sulphide deposits under the surface of vegetation. It seemed possible that the newly developed method of electrical prospecting might solve the problem. By a system of drawing equi-potential lines across the country they were able to find any rocks down to a depth of several hundred feet the conductivity of which was greater than that elsewhere. By this means the Swedes had been able to locate pyritic deposits in Sweden, and the same method was being applied in Spain. The question was whether that method might not be applied, with certain modifications suggested by experience of the country, to the great pre-Cambrian of Canada. In many cases these pre-Cambrian rocks were covered over by early Palæozoic sedimentaries. It was probable that under these sediments, which might not be of extreme depth, there were riches quite as great as those exposed near the surface. Was not it possible that by this system of electrical prospecting, or by other means, that science might develop in the future, one might find that hidden mineral wealth? He had been very interested in listening to Dr. Corless's lecture, and he thought, if it were widely read, it would make people realise the extraordinary possibilities of the great Dominion of Canada.

Dr. R. W. **Brock**, F.G.S. (Canada), said he was quite as enthusiastic and as optimistic as Dr. Corless regarding the mineral possibilities of the great pre-Cambrian area, but he thought that possibly the estimates of the agricultural land were a little conservative. Some of the area which was not included in agricultural land would prove to be of agricultural value. That was particularly the case with British Columbia, which was regarded as so mountainous as to be almost totally excluded from the area of agricultural possibilities. With regard to the copper at Coronation Gulf, he could scarcely agree that it was found on account of its accessibility. It so happened that several of the earlier explorers got into difficulties up there, where they became acquainted with the fact that the Eskimos had native copper. It was owing to that fact that definite steps were taken to get information regarding this occurrence of native copper in the Coronation Gulf. Mr. Stefansson was going up there to study the Eskimos and the fauna. He gave Mr. Stefansson some specimens to show the Eskimos so as to get them to tell him where they got them from. Dr. Douglas, who was one of the leading copper men of the United States, though a Canadian by birth, wanted to give a trip to a nephew of his, who desired to do something worth while, into some very difficult country. So he suggested to Dr. Douglas that he should send his nephew up into this Coronation Gulf district. Both Mr. Stefansson and Dr. Douglas's nephew got many specimens showing native copper. They brought back about 75 specimens of the typical copper-bearing formation of the pre-Cambrian, and native copper occurred in 72. That was obtained from various points in the neighbourhood of the Coronation Gulf. Dr. Douglas was so impressed with its possibilities that he was quite prepared himself to undertake the prospecting and development of that country, if he could have made suitable arrangements.

Mr. William L. Griffith said that all those associated with Canada must have been greatly cheered by what had taken place that afternoon. They had had a distinguished scientist from Canada, a man of great integrity of character, whose words carried weight wherever he was known, reading a paper which had borne out so much of what Canadians hoped for, and the statements in that paper had been supported by such a great authority as Sir Richard Redmayne. Then his friend and colleague, Dr. Miller, departing from the safe ground of geology, had gone into higher altitudes and had told them that all this great wealth had been reserved by a wise providence on behalf of British subjects. He did not know that they could desire anything more than that. The Royal Society of Arts was greatly to be felicitated upon the success of the meeting. If he made a few observations somewhat personal to the Chairman, he hoped Sir Richard Redmayne would forgive him; but some years ago Dr. Miller came over to this country on behalf of the Dominion Government to conduct certain negotiations, and he called upon him asking: "Do you know Sir Richard Redmayne?" He said: "No, I do not, but I hear he is clever and energetic, and you will have to watch him, because these English officials have a way, when they want to build up an organisation, of putting the English in the middle and the Dominion representatives as satellites revolving round. I think, therefore, you had better watch him." He saw Dr. Miller some time after that and said: "Well, what about Sir Richard Redmayne?" and Dr. Miller said: "He is a splendid fellow. He seems very reasonable, and I think we shall get along with him." Ultimately, he (the speaker) came to know Sir Richard Redmayne, and to know him was to trust him. However dense the domestic official fogs were in his office, when Sir Richard Redmayne called his genial presence dispelled them, and he had found that his own connexion with him justified Dr. Miller's description fully. They heard a good deal about constitutional difficulties within the Empire which were going to create all sorts of troubles, and which were going to break the Empire to pieces; but his view was that, if they had administrators of the capacity and geniality of Sir Richard Redmayne, all these difficulties would pass away. Tact in administration was the great thing. It did not matter what the law was or even what the Constitution was so long as they had men like Sir Richard Redmayne to carry on negotiations between the Englishman and the, perhaps, somewhat susceptible Dominion representative. He had great pleasure in expressing their thanks and appreciation for the thoroughly useful and cheerful prospect presented by Dr. Corless in his paper. They were living at a time of impending financial doom; but perhaps Lord Durham was right when he said he called upon the young land of Canada to redress the balance of the old world.

Dr. Henry M. Ami, F.G.S. (Canada), said he had great pleasure in seconding the vote of thanks to Dr. Corless for his magnificent presentation of the mineral wealth of the pre-Cambrian, and to Sir Richard Redmayne for his kindness in presiding. When 2,000,000 square miles were in the balance it it meant a great deal. There was one mineral, however, which had not been referred to, namely, the diamonds; eight of them had been found in the gravel south of the present international boundary line. When would the diamond field of Canada or of the pre-Cambrian be discovered?

Sir Richard, as Chairman-Governor of the Imperial Mineral Resources Bureau, had done good work for the Empire. He was doing it well, and it was hoped that he would long continue to take the active part he had taken in advancing the welfare of the great Empire, to which we belong.

Dr. Corless briefly acknowledged the vote of thanks.

Sir Richard Redmayne expressed his thanks and gratitude to Mr. Griffith, who had always helped him with his advice and sympathy. He would like to take this opportunity of publicly expressing his thanks to Mr. Griffith for his kindness during the time he was occupying a very important position in the Canadian Office in London, as representing the great Dominion.

LA VIE INDUSTRIELLE EN FRANCE.

L'Autodrome de Miramas, près de Marseille.

Jusqu'ici la France ne possédait pas d'autodrome, et les courses et concours d'automobiles, qui ont un succès de plus en plus grand, devaient être organisés sur des circuits improvisés empruntant les routes. Cette solution présente des difficultés et des dangers, aussi a-t-on décidé la construction de deux autodromes : l'un à Montlhéry, à une vingtaine de kilomètres de Paris, est en construction, et l'autre, à Miramas, près de Marseille, a été inauguré le 13 Juillet.

L'autodrome de Miramas est un des plus grands existant jusqu'ici. Sa piste a, en effet, une longueur totale de 5,000 mètres (5,470 yards), tandis que celui de Brooklands n'a que 4,630 yards et celui d'Indianapolis (U.S.) 4,410 yards. La piste de Miramas se compose de deux lignes droites réunies par des arcs de cercle de 150° ; entre les droites et les arcs se trouvent des raccordements paraboliques. L'ensemble occupe une longueur de près de 2,000 mètres (2,187 yards) et une largeur de 960 mètres (1,050 yards).

La piste a une largeur de 16 mètres (52ft. ½), avec une pente transversale de 2.75% dans les parties en alignement droit et de 5% environ dans les parties circulaires. La piste est prolongée vers l'intérieur par une contrepiste en terre de 5 mètres, et vers l'extérieur par une contrepiste en remblai de 4 mètres.

Une petite piste triangulaire a été établie à l'intérieur, à une extrémité, pour permettre d'imposer à volonté aux véhicules, des virages très courts, pour certaines épreuves.

Le terrain se prêtait très bien à l'établissement d'une piste ; il est plat, et à très faible profondeur se trouve un poudingue incompressible. La superstructure est constituée par un revêtement en béton de ciment de 15 centimètres (6 in.) d'épaisseur. Les matériaux pour constituer ce béton ont été excavés a proximité de l'autodrome, sous la couche de poudingue. Le béton a été mis en place suivant la méthode américaine, au moyen d'une machine Lakewood. Cette machine est constituée par un pont roulant automoteur, se déplaçant sur deux rails spéciaux, qui servent en même temps de coffrages latéraux pour le béton. A l'avant se trouve un gabarit de tôle qui répartit le béton ; à la suite est placé un madrier pilonneur ; à l'arrière, enfin, agit une courroie de finissage.

Les tribunes, placées sur un des grands côtés, ont une longueur de 300 mètres, et comportant 12 rangs de gradins en béton armé. La couverture, également en béton armé, présente un porte-à faux de 10 mètres, sans aucun point d'appui intermédiaire.

A l'intérieur de la piste, en face des tribunes, se trouve un pavillon contenant les services des postes et télégraphes pour la presse, avec poste de T.S.F., une salle pour les journalistes, une autre pour les chronométreurs, et sur la toiture les tableaux d'affichage. Un mur de cloture de 7,500 mètres de longueur totale entoure la piste, en réservant des espáces où pourront se garer les automobiles.

La première course, le 13 Juillet, a montré le bon fonction de l'autodrome et de ses services annexes.

La Société de Recherche et de Perfectionnements Industriels.

L'application des recherches scientifiques à des buts industriels est réalisée en France dans plusieurs établissements nationaux, et principalement au Conservatoire des Arts et Métiers, à Paris, et à l'Office National des Recherches scientifiques et industrielles, à Bellevue, près Paris.

Plusieurs savants et industriels ont jugé cependant utile la création d'une organisation privée, indépendante de ces établissements officiels, et ils ont constitué la Société de Recherches et de Perfectionnements Industriels.

Cette société offre aux industriels d'exécuter pour eux les recherches scientifiques dont ils ont besoin pour améliorer leurs fabrications, ou pour trouver des procédés noveaux répondant à des besoins spéciaux. Des conditions établies dans chaque cas fixent la rémunération demandée à l'industriel, et les droits éventuels de la Société aux bénéfices des inventions qu'elle pourra faire breveter.

La Société a déjà réalisé des recherches importantes, et elle en poursuit d'autres. Elle étudie notamment la combustion du charbon pulvérisé, en vue d'améliorer les appareils employés jusqu'ici à cet usage. Elle a mis au point un procédé de purification des charbons cendreux, en partant des méthodes de l'inventeur américain William Trent. Elle a trouvé divers perfectionnements aux procédés de goudronnage des chaussées, d'imprégnation des pavés de bois, de briquetage, etc. Elle a aussi monté une usine d'imprégnation, qui fournit des pavés de bois à la Ville de Paris.

D'autres études sur la putrescibilité des farines, sur les laques, sur le traitement des eaux d'égout, etc., ont été réalisées. Enfin, le service mécanique de la société a imaginé et construit des balances destinées à être suspendues à des grues, ponts-roulants, etc., et dans lesquelles les couteaux sont remplacés par des roulements à billes.

Bien que fondée depuis peu, la Société a déjà résolu d'importantes questions industrielles, et en étudie actuellement un assez grand nombre.

Chacune de ces études est faite à la demande d'un industriel, et les résultats en sont tenus complètement secrets.

Les Installations Mécaniques et la Protection contre l'Incendie aux Nouveaux Magasins du Printemps, à Paris.

Les Magasins du Printemps occupent, au centre de Paris, deux vastes immeubles entre la Boulevard Haussmann et la rue de Provence, sans compter deux magasins annexes, donnant également sur la rue de Provence. En Septembre, 1921, au moment où l'on s'apprêtait à finir la construction du second de ces immeubles, entrepris dès avant la guerre, un incendie considérable la dévasta en quelques heures. La charpente métallique fut fortement éprouvée et il fallut la démonter entièrement, pour remettre les fers en bon état ou les remplacer, avant de les assembler de nouveau.

Ces travaux de reconstruction, tout importants qu'ils soient ne mériteraient pas une mention particulière, si l'on n'en avait pas profité pour mettre les nouveaux magasins au premier rang des progrès accomplis dans la protection des édifices publics contre l'incendie, et dans l'aménagement des magasins suivant les méthodes les plus modernes.

Les nouveaux Magasins du Printemps couvrent 5,000 mètres carrés (53,820 sq. ft.) et comprennent deux grands halls de 6 étages, couverts par des dômes dont le sommet atteint 40 mètres (131 ft.) de hauteur au-dessus du boulevard. Ces deux halls sont séparés par une cage centrale fire proof, comprenant 12 ascenseurs et 2 escaliers, dont un mécanique, ainsi que par des doubles rideaux (coupe-feu). De même, les cages d'escaliers sont fire proof, et les vitrages sont constitués par de petits carreaux enchâssés dans une monture métallique.

Plus de 6,000 sprinklers sont disséminés dans les plafonds, à tous les étages, et un réseau d'avertisseurs d'incendie, du système "Thermosonus," est également réparti à tous les étages; il permet, de même qu'un réseau téléphonique spécial de sécurité de signaler à un poste central de surveillance toute température anormale dans un endroit quelconque.

Les canalisations d'eau sont multiples, et agencées de façon à faciliter la défense contre le feu. Une centaine de postes d'incendie sont également répartis un peu partout.

Bien entendu, les magasins sont reliés directement au poste des pompiers de la Ville de Paris.

L'éclairage est très important: on n'a pas hésité à porter à 60 bougies par mètre carré l'intensité de l'éclairement des surfaces de vente, au moyen de lampes de 400 bougies, enfermées dans des globes diffuseurs. Avec les lampes décoratives disposées en cordon le long des balcons, etc., on arrive à un total de 18,000 points lumineux, sans parler des illuminations extérieures, pendant les fêtes par exemple.

L'éclairage complet n'exige pas moins de 1,200 kilowatts, et le courant de force (ascenseurs, escalier mécanique, ventilateurs, réseau pneumatique, etc.), exige 600 kilowatts.

La partie la plus nouvelle de l'agencement des magasins, au point de vue de la vente, est la centralisation des opérations de caisse dans deux caisses centrales, reliées aux rayons de vente par un réseau de tubes pneumatiques: on envoie ainsi du rayon à la caisse les papiers concernant les achats, et aussi, en cas de paiement immédiat, l'argent remis par les clients; la caisse renvoie la monnaie au rayon, par le même système.

DEVELOPMENT OF NORTHERN MANCHURIA.

The population of northern Manchuria has increased from 2,000,000 to 12,000,000—equal to the estimated population of Siberia—since the inception of the Chinese Eastern Railway, which operates over 1,100 miles in this district, according to a report by the United States Commercial Attaché at Peking. The greater part of this increase, moreover, has occurred in the past decade. There are about 200,000 Russians.

Agriculture yields 83 per cent. of the total production value of northern Manchuria and constitutes more than 90 per cent. of its exports. The principal agricultural products are timber, soya beans and wheat. Field crops in 1922 aggregated 9,500,000 short tons, 22 per cent. of which consisted of beans and 17 per cent. of wheat. The balance, 61 per cent., was in kaoliang (kaffir corn), millet, maize, and other grains. The 35 modern flour mills in the railway zone consume 10,000,000 bushels of wheat annually. The value of the output of the bean-oil mills in this area is equal to one-half that of the production of the flour mills.

Of the 600,000,000 head of sheep produced in the world, China may claim 45,000,000 head, one-half of which come from Mongolia and Manchuria, with 11,000,000 head in the region contiguous to the Chinese Eastern Railway. This territory produces 3,500,000 head of horses, 5,000,000 head of large-horn cattle, and 3,200,000 pigs.

GENERAL NOTE.

Madagascar Ant Wax.—Considerable activity has taken place recently, writes the United States Consul at Antananarivo, in the gathering and exportation of a product called "lokombitsika," a kind of gum or wax produced principally in the Province of Fort Dauphin, in the southern part of Madagascar. This material is said to be formed on the branches of trees in the forests by a kind of ant insect known as the "Gascardia Madagascariensis." Its exportation has been confined recently to France, where it is employed in connexion with the manufacture of varnish and possibly for other purposes. It is sometimes sold as gum lac. Previous to the war sample lots of this wax were sent to Germany by the German firms then doing business in Madagascar. The gathering season would appear to be from June to September, and the average quantity now being produced or taken is reported as about 50 to 75 tons per year.

Journal of the Royal Society of Arts.

NOTICE.

COMPETITION OF INDUSTRIAL DESIGNS.

On Tuesday, August 12th, the Queen, attended by Lady Bertha Dawkins, honoured the Royal Society of Arts by visiting, the Exhibition of selected works submitted at the Society's Annual Competition of Industrial Designs, which is now being held, by the courtesy of the Director, in the North Court of the Victoria and Albert Museum, and remains open until Saturday, 30th inst. Her Majesty was received by Lord Askwith, K.C.B., K.C., D.C.L., Sir Frank Warner, K.B.E., and Mr. Carmichael Thomas, members of Council. Sir Cecil Harcourt Smith, C.V.O., LL.D., Director of the Victoria and Albert Museum, and Mr. Eric Robert Dalrymple Maclagan, C.B.E., were also present. The Queen evinced great interest in the Exhibition, and graciously expressed her desire to purchase one of the designs.

The following Report on the competiton of Industrial Designs has been issued :—

INTRODUCTION.

One of the chief objects of the Royal Society of Arts was declared by its founder to be "the training of young people for the pursuit of the Industrial Arts." In the very first list of premiums, published in 1754, a set of prizes was offered for boys and girls between fourteen and seventeen for "the most ingenious and best fancied designs, composed of Flowers, Fruit, Foliage and Birds, proper for Weavers, Embroiderers, or Callico Printers"; and a similar set of prizes was offered to children below the age of fourteen, in the hope, it has been said, that their fresh young minds might produce something less hackneyed than the designs then available. For many years similar prizes were offered by the Society; a large number of awards was made; and in 1778 it was claimed that "the elegance of pattern adopted by weavers and callico-printers may with justice be attributed in a great degree to the rewards and attention bestowed upon them by the Society."

In the earlier part of the nineteenth century the Society for various reasons discontinued these awards and turned its attention elsewhere; but in 1876 a small trust fund was handed over to it, to establish a memorial to the well-known architect and ornamental designer, Owen Jones, and since then a number of prizes have been awarded annually to students in Schools of Art. These competitions met with a reasonable amount of success, but it was felt by the Council that a great deal more might well be done to encourage not only the student but also the young practising designer. As a beginning they appointed five strong committees, consisting mainly of manufacturers, to deal with Architectural Decoration, Textiles, Furniture, Book Production, and Pottery and Glass, with a Central Committee under the chairmanship of Sir Frank Warner, K.B.E. These committees were unanimously of opinion that the best means of bringing to light young designers of promise was to hold an annual competition open to two classes of competitors—(*a*) students in British Schools of Art, and (*b*) all British subjects. In order to add to the attractiveness of the competition it was decided to offer money prizes, medals, and, if possible, travelling scholarships, while in cases of very exceptional merit, it was proposed that the Society should confer its Diploma which, it is hoped, will soon come to be recognised as the hall-mark of a first class designer. The Committees further decided to hold exhibitions of the selected designs in London and possibly in other suitable centres, in order that the competitors might have their work brought prominently to the notice of manufacturers most likely to be interested in it.

About a year ago the various committees issued appeals for funds, with the gratifying result that over £1,000 was subscribed, almost entirely by manufacturers, to provide scholarships and prizes at the 1924 competition. Unfortunately, it was not found possible to hold a competition in architectural decoration this year, although it is hoped that this defect may be remedied in 1925; but a Miscellaneous Section was added in which substantial prizes were offered by two well-known firms.

Particulars of the First Competition were issued and widely circulated at the end of 1923. The subjects of competition and prizes offered were as follows:—

CONDITIONS OF THE COMPETITION.

TEXTILES.

Designs for the following:—

(1) Carpets and Rugs.
  Moquettes.
  Floor Coverings: Linoleum and Floor Cloths.
(2) Tapestries.
  Damasks, Brocades and Figured Velvets for Furniture and Decoration.
(3) Printed Fabrics for Hangings and Furniture.
  Printed Fabrics for Dress.
(4) Vestments.
  Church Fabrics, including Altar Frontals, etc.
(5) Dress Brocades and Fancy Dress Fabrics.
(6) Lace; Lace Curtains.
  Embroidery.
  Open Work.
(7) Handkerchiefs.
  Tie Silks and Mufflers.
  Ribbons and other narrow goods.
(8) Bedspreads.
  Table Damasks.
  Cushion Squares.
  Tea Cosies, etc.

Candidates may submit designs for any or all of the items in any or all of the foregoing groups.

Prizes offered: The contributions to the Prize Fund are sufficient to allow of the award of one, or possibly more, Travelling Scholarships to candidates of outstanding ability. The course of study to be followed by the successful candidates will be decided after consultation between them and the Judges.

Money Prizes of not less than £10 10s. each will be awarded in each of the groups (1)—(8) at the discretion of the Judges.

FURNITURE.

The subjects of competition are as follows:—

(1) Designs for the complete Furniture of a Modern Dining Room decorated in Adam Style.

(2) Designs for the complete Furniture of a Modern Bedroom, without reference to traditional style.

(3) Designs for the complete Furniture of a Modern Sitting Room, without reference to traditional style.

(4) Designs for a Dresser, Table and Chair suitable for a Working-man's Living Room.

(5) Design for a Toilet Table in a simple style.

(6) Design for a Bookcase 6 feet long.

(7) Design for a Broadcasting Cabinet or a Gramophone Cabinet.

(8) Designs for a Garden Table, Seat and Chair.

Prizes offered: A Travelling Scholarship of £125 is offered for the best set of designs submitted in groups (1)—(3).

A Prize of £10 is also offered for the best set of designs in each of the groups (1)—(3), and a prize of £5 for the best design in each of the groups (4)—(8).

BOOK PRODUCTION.

The subjects of competition are as follows:

(1) Design for a new Type Face (12-point Pica, Roman, not Italic), including Alphabets in Capitals and Lower Case, Figures and Punctuation Marks. The size of the drawings to be not less than 4, and not more than 5, diameters.

(2) Designs for either or both of the following:—(*a*) A Title Page entirely set from type, with or without Printers' ornaments; (*b*) a Title Page partly decorated. The Title Pages to be taken from any or all of the following:—
  (*a*) "The History of Tom Jones, Foundling," by Henry Fielding. (Size, Demy Octavo.)
  (*b*) "On the Morning of Christ's Nativity," by John Milton. (Size, Crown Quarto.)
  (*c*) A Scientific Paper. (Size Demy Octavo.)

The copy in each case will be supplied by the Royal Society of Arts.

(3) Designs for Three Pages of Text, with Chapter Heading, from any or all of the books enumerated in Section 2 above, and in the sizes respectively indicated there.

The copy for (c) will be supplied by the Royal Society of Arts.

(4) Designs for any or all of the following:
  (a) A Line Illustration.
  (b) A Colour Illustration.
  (The subject of the design must be taken from a well-known book, *e.g.*, one included in the *World's Classics* or *Everyman's Library.*)
  The size of the design must not exceed 12 in. by 10 in.

(5) Design for an End or Cover Paper.

(6) Design for a Binding for "The Water Babies," by Charles Kingsley, in (a) Cloth (blocked), and/or (b) Leather (tooled).

Prizes offered: A Prize of not less than £10 10s. is offered for each of the subjects set forth above.

POTTERY AND GLASS.

The subjects for competition are as follows:—

China.

(1) Designs for a Tea Cup and Saucer, with decoration suitable for either engraving enamelling or lithographing; with or without gilding, and with or without grounds.

Earthenware.

(2) Designs for a Dinner Plate and Vegetable Dish, with decoration suitable for either engraving, enamelling or lithography; with or without gilding.

Glass.

(3) Designs for a Service of Glass (*i.e.*, a Wine Glass, a Tumbler and a Decanter) in plain form or with decoration suitable for etching, engraving or cutting.

(4) A design for either a Flower Vase or a Flower Bowl for table decoration, either in plain form or with decoration suitable for cutting.

(5) A design for a Dish or Bowl in pressed glass.

Prizes offered: First Prizes of not less than £10 10s. each will be offered in connexion with each of the groups (1)—(5). The copyright of the designs will remain the property of the successful candidates, who will also be afforded special facilities for selling their designs to the Manufacturers' Associations interested.

MISCELLANEOUS.

CADBURY BOURNVILLE TRAVELLING SCHOLARSHIP.

Messrs. Cadbury Brothers, Ltd., offer a Cadbury Bournville Travelling Scholarship of £50 in each of the four years 1924-7. The winner will be required to travel on the Continent of Europe for the development of his or her art.

The subjects for competition are any or all of the following:—

(1) A Poster.
(2) An Illustration for the Press.
(3) A Pictorial Design for a Box Lid.

SPECIAL PRIZES FOR CHOCOLATE BOX DESIGNS.

Messrs. J. S. Fry & Sons, Ltd., of Bristol, offer the undermentioned prizes for designs for Chocolate Boxes:—

(1) A design in four or five colours suitable for the Lid of a Display Box, including lettering. The subject of the design of label to be appropriate to the proposed title. Size not to exceed 11 ins. by 7 ins.

First Prize	£25
Second Prize	£10

(2) A colour design adapted for the Cover of a 1-lb. Box with Side Panels. Size not to exceed—Top panel, 8 ins. by 6 ins.; Side panel 1½ ins. deep.

First Prize	£25
Second Prize	£10

(3) A design in colours appropriate to the name "Somerdale." Size not to exceed 11 ins. by 7 ins. Special attention to be given to the style of lettering.

First Prize	£25
Second Prize	£10

The awards will be subject to the undermentioned conditions:—

(a) The Judges to be appointed shall be three in number, of whom two shall be appointed by the Royal Society of Arts and one by Messrs. J. S. Fry & Sons, Ltd.

(b) The prize-winning designs shall be the property of Messrs. J. S. Fry & Sons, Ltd.

(c) The designs submitted should be of a character that would be understood and appreciated by the general public.

(*d*) Messrs. J. S. Fry & Sons, Ltd., will supply dummy boxes required.

"OWEN JONES" PRIZES.

In addition to the prizes mentioned above, the Council offer six Bronze Medals under the "Owen Jones" Trust to candidates in Class (*a*) Students in British Schools of Art.

Thanks to the kind assistance of the Director, Sir Cecil Harcourt Smith, C.V.O., the Society received permission to judge the designs and afterwards to exhibit selected specimens at the Victoria and Albert Museum.

RESULTS OF THE COMPETITION.

The number of candidates who entered in all sections of the competition was 553. Of these 344 were students of Schools of Art and 209 non-students. The number of designs submitted was 1,408, divided as follows:—

Textile Section		538
Furniture Section		108
Book Production Section		214
Pottery and Glass Section		104
Miscellaneous Section—		
Prizes offered by Messrs. J. S. Fry and Sons, Ltd.	342	
Travelling Scholarship, offered by Messrs. Cadbury Bros., Ltd. ..	102	
		444
		1408

The Schools of Art from which candidates entered were :—

[The numbers in brackets show the number of candidates from each school.]

Batley (1); Bath (2); Battersea (7); Belfast (4); Birkenhead (2); Birmingham (Birchfields Branch School) (4); Blackburn (6); Bournemouth (22); Bradford (3); Camberwell (1); Carlisle (8); Colchester (2); Coventry (3); Croydon (6); Darlington (9); Derby (10); Dewsbury (3); Doncaster (2); Dublin(2); Edinburgh (1); Farnham (1); Glasgow (1) Glossop (4); Godalming (1); Goldsmiths' College, London (4); Great Yarmouth (1); Guildford (2); Hammersmith (9); High Wycombe (2); Hornsey (28); Ipswich (1); Keighley (3); Kendal (2); Kingston-on-Thames (2); Lancaster (7); Leeds (9); Lewes (2); Leyton (16); Liverpool (21); L.C.C. Central School of Arts and Crafts (3); Macclesfield (19); Manchester College of Technology (2); Manchester School of Art (15); Nottingham (5); Paignton (1); Penzance (1); Putney (1); Rochester (1); Royal College of Art (1); Sheffield (16); Southend (3); Southport (10); Sutton, Surrey (1); Todmorden (1); Torquay (4); Watford (24); West Bromwich (13); Worcester (2); Wordsley (7).

The Judges were appointed by the Council of the Society on the recommendation of the various Sectional Committees. Their names are as follows :—

TEXTILES.

Sir Frank Warner, K.B.E., Chairman of the Textile Section Committee,—Peter Adam, Esq., G. P. Baker, Esq., T. C. Dugdale, Esq., Lady Horner, O.B.E., A. F. Kendrick, Esq., Thorold D. Lee, Esq., C. E. C. Tattersall, Esq., and A. Herbert Woolley, Esq.

(Professor R. Anning Bell, R.A., and Sir Banister Fletcher, F.R.I.B.A., were also appointed judges, but were unable to attend.)

FURNITURE.

W. Nelson Bridges, Esq., C. A. Richter, Esq., H. D. Searles-Wood, Esq., F.R.I.B.A., L. A. Shuffrey, Esq., and W. Stewart Greene, Esq.

(Sir Banister Fletcher, F.R.I.B.A., Ambrose Heal, Esq., and J. Murray Reid, Esq., were also appointed judges, but were unable to attend.)

BOOK PRODUCTION.

J. A. Milne, Esq., C.B.E., Chairman of the Book Production Section Committee, Laurence Binyon, Esq., LL.D., F. V. Burridge, Esq., R.E., A.R.C.A., F. J. Hall, Esq., George W. Jones, Esq., Major R. Leighton, C.J. L'Estrange, Esq., James Maclehose, Esq., LL.D., F.S.A., G. H. Palmer, Esq., A. W. Pollard, Esq., C.B., D.Litt., F.B.A., and Emery Walker, Esq.

POTTERY AND GLASS.

E. R. Edis, Esq., Chairman of the Pottery and Glass Section Committee, Percy Brooks, Esq., Harold Plant, Esq., E. J. Purser, Esq., Bernard Rackham, Esq., W. Savill, Esq., and Herbert Webb, Esq.

CADBURY-BOURNVILLE TRAVELLING SCHOLARSHIP.

F. V. Burridge, Esq., R.E., A.R.C.A., and J. A. Milne, Esq., C.B.E.

PRIZES OFFERED BY MESSRS. J. S. FRY AND SONS, LTD.

F. V. Burridge, Esq., R.E., A.R.C.A., R. L. Hanover, Esq., and J. A. Milne, Esq., C.B.E.

The judges met at the Victoria and Albert Museum on July 1st, when they examined the work submitted, and drew up the following Reports :—

TEXTILES.*

SUB-SECTION 1, including carpets and rugs; moquettes; floor coverings; linoleums and floor cloths.

---

* In the conditions of the Competition set forth above, the Textile Section was divided into eight Sub-Sections. For the purposes of judging it was divided into five Sub-Sections.

The designs in this section are comparatively few in number, and of no special merit.

The carpet design No. 192 (the work of James Aitchison, Glasgow School of Art) contains some original features. The border is a little weak and out of tune with the centre. The colour is good.

Two designs for floor coverings, No. 90 (the work of Thomas Forret), are fair examples of students' work.

No prize is awarded in this section.

SUB-SECTION 2, including tapestries; damasks; brocades and figured velvets for furniture and decoration; vestments; church fabrics, including altar frontals, etc., and table damasks.

A prize of £10 10s. is awarded to Eric Edward Taylor (School of Arts and Crafts, Battersea Polytechnic) (No. 551) for a design for a tapestry panel.

Prizes of £5 5s. each are awarded to :—

Miss Doris Duckworth (City School of Art, Liverpool) (No. 327) damask table cloth.

Miss Rebecca Viney (School of Art, Farnham) (No. 114), for the promise of her work, but not the execution, and for general merit in the Textile Section.

The following are commended :—

Herbert Woodman (No. 432).

Miss Marjorie E. Brown (School of Art, Torquay) (No. 63).

SUB-SECTION 3, including printed fabrics for hangings and furniture; bedspreads; cushion squares; tea cosies, etc.

A prize of £10 10s. is awarded to Miss Eleanor Joan Palmer (Municipal School of Art, Manchester) (No. 162), cretonne hanging.

A prize of £5 5s. is awarded to James Hanson (School of Art, Technical College, Blackburn) (No. 147), cushion square.

The following are commended :—

Miss Ethel M. Bennett (No. 224).

Miss T. M. Bowyer (No. 441).

William James Grout (Correspondence College for Applied Design, Nottingham) (No. 396).

Miss Gertrude Mary Harris (No. 29).

Miss Winifred Mee (Municipal School of Art, Manchester) (No. 159).

Miss Phyllis Ramage (Municipal School of Art, Manchester) (No. 161).

Miss Mary Stansfield (Municipal School of Art, Manchester) (No. 160).

SUB-SECTION 4, including printed fabrics for dress; dress brocades and fancy dress fabrics; handkerchiefs; tie silks and mufflers; ribbons and other narrow goods.

Printed Dress Fabrics.—A prize of £10 10s. and an Owen Jones bronze medal are awarded to Miss Elizabeth Wilson-Haffenden, Croydon School of Art, for design 3 on the sheet No. 301. This design is good technically and excellent both in *motif* and colour. The other two designs on the same sheet are poor in colour.

The following designs are commended :—

No. 442. Print for voile. Miss Elsie McNaught.

The *motif* and colour are good, but the design is not very accomplished technically, and the work should be more careful so that the engraver may understand clearly what is intended and what is merely accidental.

No. 371, by Miss Joyce Gregory, Hornsey School of Art.

The design is pleasant and gay in colour.

The rest of these designs show a moderate average of technical knowledge and of facility in execution. Instead of using bright schemes the competitors' sense of colour seems to be dulled. A study of old colour prints and old colour brocades, especially of the specimens in the Victoria and Albert Museum, is strongly recommended. Much more attention should be given to good drawing of *motifs*. In many cases this is too mechanical and uninteresting. The purpose for which the material is to be used should be kept constantly in mind when the design is being made. In one case only (No. 283) is direct evidence given that the idea of dress is conceived before the pattern is made, and a prize of £5 5s. is awarded to the designer, Miss Kate Muriel Gee.

Woven Dress Fabrics.—In this section, although some of the designs are satisfactory from a weaving point of view, the *motifs* are very uninteresting, and the colour generally is muddy and dull.

Fancy Dress Fabrics.—Amongst these works there seems to be no sense of gaiety of colour or suitable design. Some idea of the fancy dress in the mind of the designer might be submitted with the design.

Handkerchiefs, Tie Silks, etc.—This part of the competition is distinctly bad. The technical qualities are poor and the artistic qualities very poor.

There seems to be but little indication in the work submitted that students are made familiar with the trend of fashion. This is a most important factor in designing any dress fabric, as, after all, tradition is the outcome of a series of fashions, and fashion has at the present time a great influence on the type of design necessary.

The judges feel strongly that this first competition instituted by the Royal Society of Arts should be dealt with very seriously, for the regrettable gulf which has opened between art and manufacture must be bridged without delay if this country is to regain her pre-eminence in commerce.

SUB-SECTION 5, including lace; lace curtains; embroidery and openwork.

Prizes of £10 10s. each are awarded to:

Mrs. Ella Hodgett (School of Art, Glossop), No. 346, Lace bedspread.
Miss Gladys Ruth Adams, No. 217, Embroidered blouse.

Prizes of £5 5s. each are awarded to:

Miss Daisy Rogers Stedman (Correspondence College for Applied Designs, Nottingham), No. 401.

Miss Jane Kirkbride (School of Art, Storey Institute, Lancaster), No. 257.

Commended:

Miss Doris Cook (Hornsey School of Art) No. 370.

The designs submitted in this sub-section were few, and none except those mentioned above call for special mention.

FURNITURE.

The following awards are recommended:

(1) Design for the complete furniture of a modern dining room decorated in Adam style.

Prize of £10 and an Owen Jones bronze medal: Herbert Stanley Froude (School of Art, Goldsmiths' College) (No. 429).

Commended: Duncan M. Grassie (No. 227).

(2) Design for the complete furniture of a modern bedroom, without reference to traditional style.

Prize of £10: Edward Herbert Hill (No. 292).

Commended: Harry Norris, jun. (No. 447).

(3) Complete furniture of a modern sitting-room, without reference to traditional style.

Prize of £10: Edward Herbert Hill (No. 292).

Commended: Sidney Leonard Neale (No. 298).

(4) Dresser, table and chair suitable for a working man's living room.

Prize of £5: Edward Herbert Hill (No. 292).
Commended: James Edward Crane (No. 237).

(5) Toilet table in a simple style.

Prize of £5: Edward Herbert Hill (No. 292).

(6) Bookcase.

Prize of £5: Patrick Casey (School of Art, Barnstaple) (No. 17).

Commended: Frederick Sidney Maude (School of Art, Ipswich) (No. 234).

(7) Broadcasting cabinet or gramophone cabinet.

Prize of £5: James Edward Crane (No. 237).

Commended: Edward Herbert Hill. (No. 292).

(8) Garden table, seat and chair.

Prize of £5: Patrick Casey (No. 17).

The Travelling Scholarship of £125 is awarded to Edward Herbert Hill.

BOOK PRODUCTION.

1. NEW TYPE FACE.

There is some evidence that the few competitors for this prize have looked at modern Roman alphabets but little to show that they have profited by the study. The designs sent in are wholly unsuited as copy for the engraving of type punches for the production of type for the printing of books, and no jobbing printer who respected his work would use them if they were. The truth is, type design is rather too difficult a job for an amateur and only these apparently have competed.

The competitors have not understood that only the most trifling variations from the established forms are possible. The standard set by the Venetian printers of the fifteenth century, the French printers of the sixteenth, and our own Caslon of the eighteenth century, are, if not the last word in Roman letter, hardly to be departed from with impunity. All types based on these forms or even those of Didot and Bodoni, the progenitors of our "Modern" face, are eminently *readable*. Readability and not eccentricity should be the aim of the type designer in addition to as much beauty as he can compass.

It is with regret that the judges can make no award.

2. TITLE PAGES.

Prize of £10 10s.: Peter Carruthers (No. 100).

Highly commended: T. F. Garside (Manchester School of Technology) (No. 541).

3. SETTING OF THREE PAGES OF TEXT.

No awards are recommended in this subsection.

4. LINE AND COLOUR ILLUSTRATIONS.

The judges do not consider that any of the work in this sub-section shows the least attempt to respond to the call for that advance in the standard of work which it was hoped would result from this competition, and they recommend that the prize of £10 10s. be not awarded. They desire, however, to commend generally the work of the Hornsey School of Art, and they recommend that an Owen Jones bronze medal be awarded to Miss Lorna Steel.

In the sub-section of colour illustration, they commend the work of George Whitfield Dix (No. 449).

5. END OR COVER PAPER.

Prize of £10 10s.: Miss Evelyn Gwendoline Maw (L.C.C. Central School of Arts and Crafts), No. 77.

6 (*a*) CLOTH BINDING.

Commended: Miss Ellen M. Woodward-Reid (No. 424).

6. (*b*) LEATHER BINDING.

The judges recommend that the prize of £10 10s. be equally divided as follows:—

Prize of £5 5s.: Miss Mary G. Gibson (No. 225).

Prize of £5 5s.: Francis Glanville Garrett (No. 212).

Commended: Miss Hazel M. Montgomery (City School of Art, Liverpool), No. 340.

POTTERY AND GLASS.

POTTERY.

The judges call attention to the almost complete lack of originality in the designs submitted. There is too strong a tendency to cling to present and past practice, and no suggestion of fresh ideas.

Many of the shapes are not practicable from the standpoint of utility or of potting. Handles on cups and tureens are either too large or too small. Saucers are too flat to fire safely, and tureens too shallow for use. In many cases handles are so placed and drawn as to invite breakage. In one case the tureen is without handle at all.

Beauty of outline is not sufficiently in evidence.

The designs for dinner services are particularly disappointing. They are mostly overdone, and differ but little from what has been on the market for the last twenty years.

China: designs for a tea cup and saucer.

Miss Kathleen Waine (No. 86A) is commended and recommended for an Owen Jones bronze medal.

Earthenware.

No awards are recommended in this sub-section.

William Frederick Godfrey (No. 427) shows distinct merit, but his entry is not complete, and does not fulfil all the conditions of the competition. He has a good idea of constructing a pattern, but the tendency towards over elaboration should be controlled, especially in pottery.

GLASS.

The judges consider that in this sub-section the designs in general are encouraging, and that the competitors have given careful thought to the requirements of the material and its manufacture.

They recommend that a prize of £10 10s. be awarded to Reginald Edward Edgecombe (No. 230) whose work shows great merit and mastery of the technique of the processes of manufacture. In some of his designs he has not given sufficient attention to the cost of production, and in one case, a bowl, the fragility of the top is unsuited for practical use in present-day conditions.

Of the students, the work of Leonard Green (Wordsley School of Art) (No. 153) is very meritorious, and he is recommended for an Owen Jones Bronze Medal. The design for a cut table service is effective, and the pressed bowl is also good, the scalloping of the edge being satisfactory, without the fault of fragility.

MISCELLANEOUS.

CADBURY BOURNVILLE TRAVELLING SCHOLARSHIP.

Mr. Rowland Frederick Hilder (No. 312) (School of Art, Goldsmiths' College), exhibited work in all three parts of this section, viz., a poster, an illustration for the press, and a pictorial design for a box lid, and his work was the best in all three. The judges consider him to be a very promising young artist, and recommend that he be awarded the Cadbury Bournville Travelling Scholarship of £50 for 1924, and also an Owen Jones Bronze Medal.

Miss Kathleen Ardern, poster (Sheffield School of Art), (No. 117) is commended.

PRIZES FOR CHOCOLATE BOX DESIGNS OFFERED BY MESSRS. J. S. FRY & SONS, LTD.

The competition did not produce work of sufficiently high standard to justify the award of the full prizes of £25, which were offered by Messrs. J. S. Fry & Sons, Ltd. Several designs, however, showed considerable merit, and the following awards are made :—

(1) For a design in four or five colours suitable for the lid of a display box :—

Prize of £10 : Maurice Campbell Taylor, (Bradford School of Art) (No. 489).

Prizes of £5 each : Mrs. Dorothy Mary Stanford (No. 20).

F. W. Sheppard (Leeds School of Art) (No. 319).

Leo Hardy (Sheffield School of Art) (No. 480).

(2) Colour design for cover of a 1 lb. box :—

Prizes of £5 each: Frederick Angus Horn (Bradford School of Art). (No. 543).

William Richard Pearson (No. 423).

Miss Antonia Young Hall (School of Art, Bournemouth) (No. 133).

(3) Design in colours appropriate to the name "Somerdale" :—Prizes of £5 each :

Ernest Male (City School of Art, Liverpool) (No. 333).

Walter McDade (No. 405).

Mrs. Dorothy Dix (No. 448).

William Knight (No. 37).

On the whole, the judges consider that the results are satisfactory, especially when it is borne in mind that this year the competition is being held for the first time. The number of designs submitted in all the sections was 1,408, and this would no doubt have been very considerably increased if it had been found possible to include the subject of architectural decoration. With regard to the quality of the work, in no case did it reach the diploma standard, and the judges were able to award only one of the three travelling scholarships which were offered ; but although in some sections the results were disappointing, in others, especially in certain sub-sections of Textiles, Furniture and Glass, several of the designs showed considerable promise. The committees hope that those candidates who have received prizes or commendation will be encouraged to devote themselves more eagerly to their work, and to produce still better designs at future competitions. They trust, also, that as the competitions become more widely known the number of candidates will increase and the quality of the designs will improve. If the best of our young designers can be induced to send in their work to these competitions, there is little doubt that manufacturers will soon begin to look to the exhibitions when they require the services of a first-class designer.

In announcing the awards, the Council desire to express their thanks to the Judges for the care which they have devoted to the work, and for the promptitude with which the awards have been made.

They wish also to state their warm appreciation of the assistance rendered to the Society by the Director of the Victoria and Albert Museum and his staff.

An Exhibition of the Designs submitted in the Competition was opened in the North Court of the Victoria and Albert Museum, South Kensington, on July 26th, and will remain on view until August 30th next, daily from 10 a.m, to 5 p.m., and on Thursdays and Saturdays from 10 a.m. to 9 p.m.

The full conditions and arrangements for the Competition in 1925 will be announced later.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

MONDAY, JUNE 30TH, 1924.

THE RT. HON. THE EARL OF RONALDSHAY, G.C.S.I., G.C.I.E., in the chair.

THE CHAIRMAN said the Society was fortunate in having secured Mr. J. C. French to read a paper on the art of the Pal dynasty. Mr. French had spent the greater part of his working life amongst the people of India, and had acquired a very genuine interest in and love for their civilisation and culture. During his (Lord Ronaldshay's) period of office as Governor of Bengal Mr. French occupied many important official positions, and was in charge of the largest and most populous district in Eastern Bengal, the district of Mymensingh, at a time when political agitation certainly did not make the lives of district officers specially happy. But, in spite of all Mr. French's troubles and difficulties, he never permitted them to alienate his sympathies from the people amongst whom he lived, or in any way to affect his admiration for their culture; and he had made a close personal study of the subject about which he was going to speak that afternoon. No one, therefore, could be better qualified to deal with what was admittedly a little-known subject—namely, that of the art of the great Pal Empire of Bengal, which covered a period of some three centuries or so, from the 8th century A. D. onwards.

The paper read was :—

THE ART OF THE PAL EMPIRE IN BENGAL.

By J. C. FRENCH, I.C.S.

I should like to mention that this lecture is concerned with art, and not with history. But a certain historical setting is necessary, as it is difficult to treat of an art coming completely out of the void. For the history of the Pal Empire I am principally indebted to the work of the late Mr. F. J. Monahan, of the Indian Civil Service, that distinguished scholar and historian under whom I had the honour to serve as a District officer in the Presidency Division of Bengal.

The Pal dynasty reigned in Bengal during the Dark Ages in Europe, from the 8th to the 11th centuries. The flood of the Mohammedan invasion lies between us. Their only relics are the vast mounds which mark their buried cities, and the art which is our present subject.

The rise of the Pal dynasty in Bengal was preceded by a period of anarchy. From the obscure chronicle of the Rama Charitam we learn that to end this anarchy "the people forced the Goddess of Fortune on Gopala." This Gopala was the first King of the Pal line. He came to the throne by election, and we are told that he was chosen King to put an end to a condition of things described by the Sanskrit word "matsyanyayam." The literal translation of this word is "fishy." It is not an anticipation of modern slang, but is a favourite simile of ancient Sanskrit writers on political science. Anarchy is said to be fishlike because the large fish prey at will on the smaller ones. Efforts to end this anarchy in Bengal were for a time futile. The Tibetan lama Taranath in his History of Buddhism gives the reason as follows: "The widowed queen of a former King of Bengal murdered with poison everyone who was chosen to be King, but after a certain number of years Gopala was elected. He eluded her efforts to poison him, and became King for life." This story would seem fantastic to European ears, but it is exactly paralleled in our own times in Tibet. The present Dalai Lama, the ruler of Tibet, is the first for some hundreds of years to reign for any considerable length of time. All his predecessors were poisoned. Like Gopala, the present Dalai Lama has eluded his poisoners. The throne to which Gopala was elected was that of Gauda. This name is now applied to the ruins of a a great city in the Malda District, but in ancient times it included the whole of Northern Bengal. Gopala extended his sway over the neighbouring Kingdom of Magadha, now known as South Bihar. Gopala was by religion a Buddhist, but, like his successors, he tolerated and even endowed Brahminism, and the two religions existed in peace side by side. A line in the chronicle of the Rama Charitam describes Gopala as "sea born." What is the exact meaning of this picturesque phrase, whether it suggests the claim of a divine descent from the gods of the sea, or is merely a poetical expression of a foreign origin of the dynasty, who crossed the sea to Bengal, it is impossible to say.

This is an example of the art of the beginning of the Pal dynasty. It is an image of the goddess Chandi, and bears an inscription which gives its date as the end of the 8th century. This image was found in the district of Tippera in Eastern Bengal, and was seen by the writer in a temple of Chandi, in the south-west extremity of the Lalmai Hills, a peculiar low range rising abruptly from the alluvial plain.

Now this image has disappeared, stolen by thieves. It was a metal image, in an amalgam known in India as *ostradathu*, the sacred mixture of the eight metals, including gold and silver. Doubtless it has been melted down for the fragments of precious metals which might be found in it. The photograph hardly does justice to the image, and the profile view was even finer, but such as it is we must make the best of it, as the only surviving record of this most interesting work. The simplicity, dignity, and a certain immanent sense of life and significant vitality need no emphasis. For this photograph and for many succeeding ones, I am indebted to Mr. Nalini Kanta Bhattashali, the able and zealous curator of the Dacca Museum. I am also indebted to his indefatigable researches into the ancient history and archaeology of Bengal.

This small figure of Avalokitesvara is an example of the art of Bengal in the 8th century. It was also found in the Lalmai Hills, near Comilla, some years ago. It is now on exhibition in the Indian Pavilion at Wembley.

This magnificent image of Vishnu comes from Barisal. The force and power and sense of profound depth and mystery are apparent. The style in some ways recalls the Gupta period, but the mysterious and significant vitality, and the tense and nervous energy pervading the figure mark it as a fine example of the splendid period of Indian art which lies between the Hun and Mohammedan invasions. Judging from the style, this image cannot be assigned a later date than the 8th century.

This is an image of Vishnu. It is now on exhibition in the Indian Pavilion at Wembley. The elegance and strength of this figure, combined with the same mysterious sense of vitality which marks the first figure of the goddess Chandi, are characteristic of the early stages of Pal art. The perfect simplicity and restraint of the setting and scheme of decoration strike the eye, especially when contrasted with the florid over-elaboration so often associated with later images of this character. The style of the art resembles that of the first figure of the goddess Chandi. This image was found on the site of the ancient city of Mahasthan. All that remains of Mahasthan nowadays is a plateau a mile square, surrounded by a vast moat. The plateau supports an ordinary Indian village with its rice and brilliant yellow mustard fields, and only a vast pillar or massive block of stone protruding from the earth recalls the memories of its vanished glories. This plateau, which rises straight up from the plain, and is the work of man and not of nature, is an enduring evidence of the power and greatness of the Pal Empire. All the region round Mahasthan for some miles is full of traces of ancient remains. It resembles Delhi, Patna, and Malda in that it contains ruins and remains not merely of a particular period, but of several distinct epochs. For instance, the Chinese traveller Hieun Tsiang visited Paundravardhana in the 7th century, and later on Ramapala established his capital of Ramavati here. If but one hundredth part of the time and energy expended every year on excavations in Egypt were applied to this region, what interesting results might not be obtained!

In one corner of the plateau of Mahasthan stands a Mohammedan mosque. The ancient Hindu carvings and figures on the walls, and even in the stones of the steep flight of steps which lead up from the plain, bear witness to the iconoclastic zeal of its architects, and recall the days, evil to Hindu art and sculpture, of Kala Pahar and his image breakers. Kala Pahar, according to local tradition in Central Bengal, was a Brahmin, who joined the Mohammedans when they invaded Bengal, and in the destruction of images and temples showed the zeal of a convert.

Gopala was succeeded on the throne by Dharmapala, whose reign falls in the first half of the 9th century. This sovereign extended his empire far over Northern India. He conquered the Kingdom of Kanauj, deposed the King, and set up a vassal in his place. He was a reformer of the Buddhist religion. Dharmapala married a Rashtrakuta princess. The Rashtrakutas occupied the Deccan and Dharmapala sometimes allied with them in his wars against the Gurjaras, who occupied Rajputana and the Punjab. A poet described him as follows: "King Dharmapala is like to the Kalpataru (the Kalpataru is the wishing-tree of Hindu legend, that gives whatever is asked of it). What shall I say of him who is devoted to his faith, rules the earth, and is descended from the Ocean, who has the Moon for his friend?" Dharmapala was famous for his modesty. He turned away his head in confusion when he heard his praises sung by the village cowherds, by the children at play, and even by the parrots in their cages.

Dharmapala was succeeded by Devapala, a warlike King, whose war elephants penetrated the Vindhya Mountains, and his war horses visited their native home in the country of the Kambojas. The lord of Utkala, hearing Devapala's name from afar fled, while the lord of Pragjyotisha, accepting Devapala's commands, remained in peace and friendship. Devapala humbled the pride of the Huna, the Dravida, and the Gujara Kings. (The phrase of the war horses visiting their native homes in the country of the Kambojas appears obscure, but the explanation is simple. The country of the Kambojas is Tibet. Even nowadays there is a trade in horse-flesh from Tibet and the Himalayas into Bengal. The expression indicates that Devapala mounted his cavalry with horses imported from Tibet. So when he invaded Tibet the horses of his cavalry visited their native home). An inscription on a pillar tells us: "The illustrious prince Devapala made tributary the earth as far as Reva's parent, whose rocks are moist with the blood of wild elephants, as far as Gauri's father, the mountain whitened by the rays of Isvara's moon, as far as the two oceans whose waters are red with the rising and the setting sun."

It was in Devapala's reign that there flourished the only two artists whose names have come down to us, Dhiman and his son Bitpalo. Taranath in his history of Buddhism tells us:—

"In the time of King Devapala there lived in Varendra (Northern Bengal) an exceedingly skilful artist named Dhiman, whose son was Bitpalo; both of these produced many works in cast-metal, as well as sculptures and paintings which resembled the works of the Nagas. The father and son gave rise to distinct schools. In painting the followers of the father were called the Eastern school; those of the son as they were most numerous in Magadha, were called followers of the Madhyadesha school of painting. So in Nepal the earlier schools of art resembled the old Western school; but in the course of time a peculiar Nepalese school was formed, which in painting and casting resembled rather the Eastern types."

The mention of the influence of this Pal art on the art of Nepal, which continues to the present day, is interesting.

The reigns of these two Kings occupied the greater part of the 9th century. The following images are examples of the art of this period.

This is an image of the Buddhist goddess Tara. It is from a village in the district of Dacca. This image from the style of the art can be assigned to the 9th century. It conveys a distinct reminiscence of the period of Indian art sometimes known as Early Buddhistic, which includes the sculptures of the Asokan age, of Bharut, and of Sanchi. The essential continuity of Indian art is well exemplified in this figure.

This image of the Buddhist Bhairaba is also assignable to the 9th century. Like the preceding image, it comes from Eastern Bengal (Tippera district). It represents Heruka, the Buddhist Bhairaba, a terrific manifestation invoked to ward off calamities. The image wears a garland of skulls and is engaged in a ritual dance.

This is an image of a Buddhist goddess. The image was found at Mahasthan, and is at present in the museum of the Varendra Research Society. I am indebted to the distinguished and learned Secretary of that society, Mr. Akhoy Kumar Maitra, for this photograph, and also for much information concerning the history and art of this period. In this image, the art appears in a gentler and more gracious form. The whimsical and fantastic grace of the supporters form a fitting foil to the dignity and beauty of the central figure.

This small metal seated figure of the Buddhistic Lokesvara comes from the district of Dacca. Lokesvara is identical with Lokanatha the Bodhisatva of Amitabha. It is assignable to the same period as the preceding figure.

The next six kings of the Pal dynasty after Devapala are mere names, and it is not until we come to Mahipala, famous in Bengal song and story, that the mists of a thousand years clear for a moment. His accession is placed late in the 10th century. Mahipala recovered the kingdom of his ancestors, which had been encroached upon by a Tibetan invasion. Tradition ascribes to him great public works, but all that remain of them nowadays are tanks so vast as to resemble lakes and mounds and ruins. A saying is still current in Bengal which preserves his name: "Dhan bhante Mahipaler gita."—"Songs of Mahipal while husking rice." Mahipala repulsed Rajendra Chola, an invader from Southern India. Mahipala in 1026 A.D. did extensive repairs to the temples and shrines in Benares. The beginning of the vernacular literature of Bengal is ascribed to this reign. Buddhist songs in Bengali gave rise to the Kirtana songs. Mahipala was the greatest power in Northern India. It was a period of religious development, in which popular Buddhism came to be influenced by the doctrines of Tantras. "Nathas" flourished about this time. These "Nathas" were ascetics who, by the exercise of Yoga, attained to superhuman powers. They were both Buddhists and Saivas.

This figure of Shiva bears the date of the third year of Mahipal's reign, about the beginning of the last quarter of the 10th century, and is a fine example of the art of the Pal period. Carved in bas-relief on extremely hard and polished black rock, it must have taken about two years to complete. Such statues are practically indestructible from natural causes, and will yield only to the hammer of the fanatical image breaker. Below the statues on either side are the shaktis or personifications of the female energies of the deity. On either side of the deity's arms are lions, the emblems of knowledge. They are usually shown mastering elephants, as signifying the triumph of knowledge over ignorance, a somewhat singular inversion of the general idea of the intelligence of elephants. In this statue, of course, the elephants are omitted, but they are shown in a later example. At the top of the statue are the flying apsaras, while at the foot are the figures of the donor of the statue and his family.

This magnificent image of Tripura comes from the Dacca District. Tripura is the female creative principle of the universe. It is impossible to conceive a finer expression in art of profound and unfathomable meditation. This is a Brahminical image.

This is an image of Jambhala, the Buddhist god of riches. Jambhala is derived directly from the Brahminical deity Kuvera, the head of the Yakshas, and the god of ghosts and the under-world, including buried treasure. But Jambhala with his conversion to Buddhism changed his character, and we find him resembling another god of the Hindu pantheon, the elephant-headed Ganesh. Ganesh is the god of successful endeavour, of righteous increase, the apotheosis of the profiteer. The favour of Kuvera, resulting in accession to sudden and sinister wealth, was by no means so sought after by the wise as were the benefits of Jambhala and Ganesh.

This charming image of a form of Buddha comes from Western Bengal. The delicacy and grace of the art need no emphasis.

This fine image also comes from Western Bengal. It represents Pindola, a contemporary of the great Buddha, and subsequently deified as the god of medicine.

Mahipala's reign appears to have continued for the first thirty years of the eleventh century. The principal event in the reign of his successor Nayapala is the mission of Atisa to Tibet. Atisa was a principal lama in the Buddhist monastery of Vikramasila on the Ganges. Envoys came from Tibet and persuaded him to go to that country to reform the Buddhism there. It was about the year 1040 A.D. that Atisa said farewell to Sthavira Ratnakara, the head of the Vikramasila monastery. The latter was much dejected, and said that the signs promised evil for India, as numerous Mohammedans were invading the country. When Atisa, on his way to Tibet, got beyond the Nepal frontier, some Saivaites sent robbers to kill him. As soon as the robbers saw his face, they were struck dumb and motionless as statues. Atisa said, "I pity the robbers," and uttered some mantras and drew figures on the sand. The robbers were then restored to life. Further on, Atisa found some puppies dying on the roadside. He saved them, and their descendants are still to be seen at Rodeng in Nepal, a special breed. The following story is told of Atisa and one of his disciples. The disciple was starting on a journey, and with his alms-bag in his hand was bidding farewell to his master Atisa. Suddenly the disciple changed himself into a wolf, and devoured a corpse lying on the roadside. Then in a flash he turned himself into human shape again. Atisa said: "Now you can practise what form of worship you please." Atisa condemned the Tantric system for Buddhists, and once said "It is not good for a Buddhist priest to have learnt a Tantric charm from a heretic."

In Nayapala's reign an ominous event took place. The bazaars of Benares were looted in a raid by Nyaltogin, Mohammedan governor of Lahore.

Later on in the eleventh century there was a formidable revolt against the Pal dynasty by the Kaibarttas, or fishermen, led by Divvoka, who established himself as king in Central Bengal. This revolt is surmised to have indicated an interesting tendency which undoubtedly developed during the eleventh century, a reaction towards Hinduism away from Buddhism. Buddhists forbade the taking of life, and the revolting fishermen could easily have come into violent conflict with the religious tenets of their rulers. Divvoka was succeeded by his son Bhima. The latter's name is still preserved in Central Bengal by a vast embankment, which traverses the district of Bogra from north to south, passing close to Mahasthan in the centre. From long exposure to sun, wind and rain this embankment has weathered to a hardness resembling stone, and forms a striking contrast to the soft alluvial plain on either side.

Bhima was defeated and killed by Rama pala, the grandson of Nayapala. Ramapala is the hero of the Sanskrit poem Rama Charitam.

A couplet in the Rama Charitam tells us that the art of Varendra has put into the shade the art of Southern India. Another interesting reference is to be found in a royal stone inscription of the first Sen king (the immediate successor of the Pal dynasty), disclosing the existence of a guild of artists in Varendra.

Ramapala raised a great statue, of Shiva, and statues of Skanda or Kantikeya, the god of war, and Ganesh, and a lofty temple to the eleven Rudras. All this may represent a concession to the rising tide of orthodox Brahminism, of which the Kaibartta revolt may have been a sign. But the fact that he remained a Buddhist is shown by the building of the great Vihara of Jaggaddala.

Ramapala attacked Utkala, and ruled the country up to Kalinga, and his armies conquered Kamrup.

Ramapala's principal minister was descended from the ministers of earlier Pal kings. The office seems to have been hereditary, as it is in Nepal to-day.

About the beginning of the twelfth century the Pal dynasty was finally overthrown, and was succeeded by the Senas.

This image of the Buddhist goddess Maha-Prati-sara, a protecting deity of Buddhism, comes from Dacca District. Its date may be assigned to the 11th century. The style of the art is riper and more florid than in the earlier examples, and signs are not wanting that the art has reached its full zenith and is about to enter on the downward path. But these figures of the late Pal age still preserve no little of the combined strength and grace which mark this great period of Indian art.

This is an image of the boar incarnation of Vishnu. There is a certain suggestion of Javanese sculpture in the lines of this figure.

This is a figure of Vishnu of the 11th century. The lions mastering the elephants will be noted at the sides of the deity. Though this work occurs late in the course of Pal art, it is a magnificent example of the art. The suggestion of Javanese sculpture already noted in the previous image occurs here with added force. There is, however, in this work still a tense and nervous vitality, a sense of mysterious significance, absent from the softer art of the south. Figures of Vishnu of earlier periods have already been shown. A glance at these figures will indicate more clearly than many words the course of Pal art.

Here we have the art in its primitive vigour.

This is the art in a more sophisticated and developed state, in the 10th century.

This figure of Vishnu of the 11th century represents the art in the stage of full development and approaching decline.

The overthrow of the Pal dynasty by the Sena dynasty in Bengal, at the end of the eleventh or beginning of the 12th century, implies very much more than a mere change of rulers. It marks the decline of Buddhism, and the establishment of a new caste system. We have seen that Ramapala, a Buddhist King, succeeded in crushing the Kaibartta revolt, which was probably anti-Buddhist, but he only did so with the help of allied feudatory chiefs, some of whom, and among them the Senas, were favourable to religious reform. That reform, like other so-called reforms in religion, was really a return to older gods. It was a reaction against the democratic and equalising tendencies of Buddhism, and a determination to uphold and multiply social and racial distinctions. The milder religion of Buddhism was left, and a return was made to the divinities of earlier ages. The religion of Buddha, which was born in India some sixteen centuries before, and which had endured longest in Bengal, had at last come to an end, and the age-long Hinduism, of which Buddhism itself was a branch and an aspect, revived in its ancient form, and Buddhism was no longer known in the land of its birth. The exact means by which Brahminism supplanted Buddhism appear to have been the spread of Tantric doctrines. Common at first to both religions, they ultimately led to the extinction of Buddhism. At the present day the Buddhism of Darjeeling and other Himalayan countries adjoining Bengal is largely influenced by the Tantric system, and it is curious to note that nowadays in Nepal the Brahminical form of Hinduism is forcing the Buddhist religion northwards. It is also interesting to note that at the present day in India there are movements of reform and of revolt against the caste restrictions of orthodox Hinduism. In this respect these movements resemble Buddhism. One has only to mention the Brahmo Samaj in Bengal, the Arya Samaj in Northern India, and the agitation connected with the name of Gandhi (as regards the latter, in theory if not in practice) to realise the trend of modern tendencies in Hinduism.

The writer has no intention of criticising the revival of orthodox Brahminism, under the Sena dynasty, or of lamenting the decline of Buddhism. The narrower and harder form of religion was better suited to withstand the troublous times coming with the Mohammedan invasions. It is as though Hinduism instinctively collected its forces and braced itself to withstand the coming assault, a wonderful sign of the tremendous inherent vitality of this age-long system. So we find the Brahmins of the Sena age condemning the use of the vernacular language in religion, which the Buddhists had encouraged. "Who hears the eighteen Puranas or the Ramayana recited in Bengali will be thrown into the hell called Rourava." The Brahmin opposition was not mere jealous exclusion. There was a genuine fear that religious truths might be perverted or degraded and the ceremonies lose dignity by feeble or incorrect translations. In Sanskrit the ancient tradition was preserved inviolable.

The effect on art was adverse. As at this period in China and Japan, the Buddhistic system seemed to possess some affinity with the fine arts. The art of the orthodox Brahminical period succeeding the Buddhism of the Pal kings, shows distinct signs of degeneration. The art is harder, stiffer, more conventional, and with over-elaborated decoration. It is true that much of the art of the earlier period deals with deities of the orthodox Hindu pantheon. But the Buddhism which flourished side by side with it appears to have inspired its art. It is impossible to distinguish by the style of the art a Buddhistic from a Brahminical figure in Bengal, and the same is true of other parts of India. The transition in art from the Pal to the Sena period in Bengal in some ways resembles that from the Sung to the Ming period in China, Buddhism to Brahminism in the first instance, Buddhism to Confucianism in the second. The writer has no intention of suggesting that it was only under Buddhism that great art was produced in India, or that there is anything inimical in Brahminism to art. To take but one example, the great art of Rajput painting in Northern India from the sixteenth to the nineteenth centuries, is a complete contradiction to such an assertion. And indeed it could be disproved without difficulty in Bengal itself from works of art subsequent to the Mohammedan invasions. Buddhism has no monopoly of art in India, and when we consider that Buddhism is only an aspect of Hinduism, and originated from it, and, as far as India was concerned, was reabsorbed into it, this fact is not surprising. But it remains true, however, that in Bengal during the period with which we treat, with the decline of Buddhism art also declined.

Much might be said of the æsthetic theory of this art, how it is based on the Hindu doctrine of *Yoga*, the attempt to penetrate past Maya, the superficial illusion of the details of the outward form, to the essential reality of things. Bhava, the third of the ancient Hindu laws of the art of painting, and the characteristic principle of Indian æsthetic theory, which may be rendered as the influence of spirit on form, is concerned with this idea. It is interesting to note that the contemporary movement in art, sometimes known as Post-Impressionism, from Cézanne to such living artists as Matisse, and Picasso, frequently appears instinctively to incline in a similar direction—that is to say, that the artist devotes all his energy to an attempt to portray the essential character of his subject, to the neglect of its details and environment. The independence of design and its freedom from the trammels of mere representation and illusion, is another point of contact between these arts so widely separated in space and time. The large and increasing influence of the art of the East on contemporary art is an interesting question, but one which belongs rather to a consideration of Oriental art in general than of the particular branch which we are considering to-day.

The art of the Pal empire has a certain transcendental character. The artists faithfully carried out the injunctions of the Shilpa Sastras, that it was their duty to portray gods, not men. Better the image of a *god*, however rudely and unskilfully wrought, than the most brilliant statue of a *man* that a human hand could execute.

The art of the Far East is still far better known in Europe than is the art of India. It is hoped that the few examples shown to-day of one school of Indian art may serve to explain and justify an expression used in the art and philosophy of the Far East itself—San Goku, "The Three Countries," China, Japan and India.

DISCUSSION.

THE CHAIRMAN (Lord Ronaldshay) said Mr. French had given a most interesting account of the art of what must undoubtedly be described as one of the most important eras in the history of Bengal, for recent research had certainly made it clear that under the Pal kings Buddhism enjoyed a period of cultural splendour prior to its decay and its eventual disappearance from the land of its birth. Incidentally the lecturer had touched upon the ancient Hindu theory of the origin of kingship—a theory which bore a most striking resemblance to the theory known as the "social contract," which one was accustomed to think of in connexion with the names of men like Hobbes and other European thinkers of the 17th century A.D. He had told, for example, how the founder of the Pal dynasty was made king by the people, in order to bring to an end a period of anarchy, a state of affairs which, as Mr. French had said, was described by the people of those days as Mâtsya-nyâya, a word which he had translated as "fishy." A most interesting reference to the practice of electing a king to purge society of the crimes which overtook it appeared in a very ancient work on political science, the manuscript of which was found by an Indian scholar in the South of India in the early years of the present century. That work, by Kantilya, the Prime Minister of Chandragupta, the famous founder of the Mauryan Empire, which must have been founded, he supposed, about 300 years B.C. contained the following passage:—

> "People afflicted with anarchy consequent on the Mâtsya-nyâya,—the practice of the bigger fish swallowing the smaller—first elected Manu, son of Vivasvat, to be their king."

And then followed the terms of the contract which was made between the people and the person whom they selected to rule over them. "They allotted one-sixth of their grains and one-tenth of their merchandise as his share. Subsisting on this wage, kings became capable of giving safety and security to their subjects and removing their sins." Here, then, they had a perfectly plain statement as to the origin of kingship made some centuries before Christ; and Mr. French had quoted from a manuscript some thousand or more years later a passage showing that not only was that theory recognised in those days as an adequate explanation of the origin of kingship, but was actually put into practice in the times of which Mr. French had been speaking.

Turning to the art of the period, it would be agreed, he thought, that with the aid of his illustrations Mr. French had been able to give some idea of its quality, and they might well agree with him as to the interesting and valuable results which would be likely to accrue if systematic excavation on a generous scale was undertaken in Northern Bengal; for it was unquestionably the case that under the Pal dynasty, whose sway extended over the greater part of Northern Bengal, amongst other parts, there was a great flowering of Buddhist art, so much so that it had been claimed that "from the 9th to the 12th century the whole of the Buddhist world drew its inspiration in literature and art from the Kingdom of Gauda." For some years past exploration on a modest scale had been carried out, as Mr. French had said, by a body of men known as the Varendra Research Society. That society was founded by an Indian gentleman, Kumar Sarat Kumar-Roy, of Dighapatiya, and consisted of a number of Indian scholars and others interested in the work of research, who had already done valuable antiquarian work, and by their labours had thrown much light upon the history of the Pal Empire. Nearly five years ago he (the Chairman) had been privileged to open a museum at the little town of Rajshahi, in Northern Bengal, which formed the centre of the activities of the society—a museum which now housed some hundreds of pieces of stone sculpture, together with a collection of metal images, ancient copperplates and coins, as well as a fine assortment of Sanscrit manuscripts. Amongst the sculpture he recalled some beautiful images of Chandi and Vishnu similar to those shown in Mr. French's photographs. He was particularly glad of that opportunity of bearing witness to the high spirit of scholarship and research by which the members of the Varendra Society were actuated, all the more so because it was impossible not to notice in India at the present day a certain tendency to draw somewhat fanciful pictures of a resplendent past rather than to reconstruct a picture of actualities based upon critical investigation. Solid work such as that which was now being done by the Varendra Research Society certainly redounded to the credit of Indian scholarship, and called forth the gratitude of scholars, and particularly of historians, all the world over.

Mr. French's paper was so suggestive and so full of interest from such various points of view that it would certainly be easy to comment upon it at great length, but there were present that afternoon persons who were much better qualified than he to speak upon the art of the Pal period; and since the meeting was fortunate enough to have present an admirable representative from the British Museum, Mr. Laurence Binyon, he would ask him whether he would say a few words.

Mr. Laurence Binyon, LL.D., said it was very kind of Lord Ronaldshay to refer to him as if he were an authority, but he had rarely felt more ignorant than he had that afternoon in listening to Mr. French's paper. He was, however, very glad to have the opportunity of expressing gratitude to Mr. French not merely speaking for himself, but as one of a number of English students of Indian art who had not the opportunity to visit India themselves, and who were enormously indebted to sympathetic students like Mr. French for all the pains and research they were at to bring before them such beautiful objects as he had shown. He thought the qualities emphasised in the paper were just those they really had, majesty and grace, and in particular a mysterious power as of aboriginal, interior life. It was very interesting to remember that the Pal dynasty was in great part contemporary with the splendid T'ang dynasty in China, the greatest period of Chinese creative art. It was known that during that time there was living intercourse between the two countries; there were hundreds of Indian Buddhist monks in Lo Yang, the capital of China, and some of these very images might have had a direct influence on the grand Buddhist art of T'ang.

There were two points in the paper which particularly struck him. One was Mr. French's reference to Egypt and to the large sums and elaborate research devoted to Egyptian exploration, compared with the little that was done for the exploration of Indian art. However, it must be realised that it took a long time for a new art to get the necessary prestige for it to be adequately studied. What was a mere curiosity to one generation was accepted by the next as something worthy of universal study. He might mention that in the British Museum during part of the 19th century there existed what was called a Department of Oriental Antiquities. That Department no longer existed. One would have thought that oriental antiquities would have included something of the art of India, Persia, China and Japan: but there was not a single object from beyond the Euphrates. Oriental antiquities in the middle of the 19th century meant Assyria and Egypt, and that might suggest how far progress had been made in the last half century in the widening of our knowledge of and sympathies with the art of the world, and especially of the great art of Asia. While speaking of excavation and exploration he would like to express the hope that not only would money be found for increasing that work in India, but that also before very long we might have in London some representative series of good casts from the chief masterpieces of Indian sculpture. At present the Indian section at South Kensington was most inadequately housed, and very crowded, and a new building really was required. He did not think one wanted to have a great mass, but a choice selection of the most impressive, really "world-masterpieces" of Indian sculpture would be a very great boon to students, and make a great impression on the general public.

The other point that struck him was Mr. French's reference to what was called the advanced movement in art of to-day. A great many people, most people probably, found the works of those painters and sculptors antipathetic altogether; but whatever was thought about them—and he thought their efforts had not been particularly successful hitherto —it was not a question of a mere change of fashion in art. The movement of the last generation in painting was impressionism, and the chief apostle of impressionism, R. A. M. Stevenson, said the first business of the painter was to forget the fact that things existed; he was simply to regard the impression on his eye of the colours and tones, quite regardless of what they were in themselves and their essential character. The new movement was an absolute recoil from that attitude, and it was not only a question of art; he thought it had its roots in an instinctive dissatisfaction with our civilisation,—not only with our art,—which had been too much absorbed in the surface of life, and too little concerned with essentials.

Mr. A. Yusuf Ali, C.B.E., I.C.S., retired, said that in common with the rest of the audience he would like to say how much he enjoyed the very clear exposition of Pal art given by Mr. French. It was not a subject which had been often treated. In old-fashioned works like, say, Stewart's "History of Bengal," the cultural side of Bengal had been altogether neglected; in fact Stewart dealt almost exclusively with the political history from the invasion of the Muslims to the British conquest. The new fashion of bringing back history to its bearings, trying to make all the information we get from sculpture, from architecture, from paintings, mural or otherwise, bear on the life of the people and the interpretation of the political history, was one of the most welcome features of historical work at the present time. And it was of peculiar value in the case of India. When he was a child at school the history of India presented to him was a lifeless and chaotic jumble. He could not string it together, and he remembered once making a very crude remark, which he thought was justified by later experience. He was asked by a distinguished visitor to his college which history he liked best. He was expected to answer, "The history of India." He answered, instead, "The history of England." He was not unpatriotic; what he meant was that the history of England, as taught to him, presented a continuous growth, a movement amongst the people. He could see how the people began from their root beginnings; how they sculptured, as it were, their political history; how the religious reformation came and joined on with the various social and intellectual movements; how Puritanism itself led to the Stuart reaction, and how a number of such facts grouped themselves in vital relations until he could form an intelligent picture. In the history of India in those days there was practically a complete gap between the Vedas and Buddhism to the Mohammedan invasion; and although he was naturally proud of the achievements of his own people in India, he felt that it was a gap that ought to be filled. There was probably very little material in those days. Now it was accumulating, and the period of the Guptas, for instance, stood out clearly before them if they utilised the vast material that was at their disposal. For that reason he thought it would be an excellent thing if the suggestion thrown out by so great an authority as Mr. Laurence Binyon were followed up, and if they had in India—he would prefer it in Delhi, but the precise locus was of little importance—in Calcutta or Delhi or even in London, a good résumé, not of the old sort, but of the kind which brings together the cultural forces and shows the continuous development of Indian art and culture from Buddhistic and Mauryan times through the Gupta ages down to the present day. He felt that the history of India could only be understood in that way; and Mr. French's paper was an illustration in point.

The Pal period was considered a local period, but Mr. French had shown how a local period could be studied so that it could be made to fit into the general history of India; and it was only by the study of local periods that one could obtain that grasp over general history which made things clear. He was not at present quite sure whether Mr. French realised the relation between the art which he had so admirably described and Gupta art. He (the speaker) had been a very close student of Gupta art, which had a very wide geographical range. But its range in chronology seemed equally wide. The art of the age of Harsha Vardhana, whose capital was at Kanauj, in the middle of the United Provinces, was practically Gupta art. For centuries after Harsha the same traditions continued. Many examples were to be found in the United Provinces. He could not help feeling that the first beautiful example of the goddess Chandi which Mr. French threw on the screen, and which he had referred to as in some way connected with Gupta art, clearly showed the affinities of Pal art to Gupta art. He thought the perfect naturalness, the directness, the vigour of execution, were signs of an imperial spirit that knew its own mind. The attempt on the part of the sculptor to portray the benevolent features of a goddess who, at an early stage in the hitsory of India, was a very bloodthirsty goddess—witness the references to her in a play like "The Little Clay Cart" (Mrichchha Katika),—was evidence of a refinement characteristic of the Gupta tradition; and as that tradition became remote one found also that there was a debasement, a deterioration, a progress downward (if he might use an Irishism). Nothing illustrated that better than the florid examples that were thrown on the screen later. Possibly they were better in technique; certainly, to his mind, they were very much inferior in the sincerity, vigour and directness connected with all the best art.

He had no time to elaborate the theme, but he would like to end with a very brief examination of a fascinating question. In Indian art, the art inspired by Buddhism held a pre-eminent place. What was it that gave this art such a great hold over our minds compared with some of the later debased art? He did not mean to exclude Brahmanical art; he considered that the best examples of Gupta or Pala art pre-supposed Buddhist art; where Shiva or Vishnu was introduced his personality was regarded as a Buddhist would regard the personality of Buddha. It seemed to him that the Buddhist religion was specially characterised and distinguished in India from the numerous cults in the comprehensive system of Hinduism by three acts, first, that it was simple; secondly, that it appealed to the people and not to a coterie; and thirdly, that it went directly to the very deepest feelings of humanity instead of standing on a transcendent metaphysical tradition. Those characteristics in all ages were sure to give to art a pre-eminence which a merely æsthetic art could not attain. That was found in the Græco-Buddhist or Gandhava art of the best period. It was found in the Gupta art of the best period; and he was extremely glad to note the same characteristic in the early Pal art, which was Buddhist. If one took some examples of statuary which had been recently discovered in the United Provinces, they also illustrated his point. He did not know whether there was anyone in the audience who had seen that beautiful statue of Vishnu which was recently discovered in Gorakhpur, and for which a special temple was going to be built, in order that it might be fitly housed. It was of black polished marble, like the one which Mr. French had shown, and possibly it dated from either the same period or a little earlier, nearer the Gupta period. But there again, one found that although it was a statue of a Brahmanical god, it was treated with all the affection of a Mahayana Buddhist for a personal deity; it was treated with something of the familiarity with which popular religion clothed its gods and goddesses; and until one got to that sincerity, that directness, that familiarity, that desire to bring art into relation with our own lives,—until then, art must necessarily be the art of a coterie, and not a popular art. For this reason, if he were addressing an audience of his own countrymen, he would specially insist, particularly in the new art which they are building up now, and which he hoped would be a sign and symbol of that great and vigorous nationality to which India was looking forward, that in that art they must try and study the facts of present life, and apply all the technical knowledge and skill they could attain in order to interpret it, and not merely be lost in the mazes of a more or less vague or elusive tradition.

He had much pleasure in bearing his testimony to the value of Mr. French's paper, and perhaps it would also be permissible to hope that a similar attempt would be made to interpret Gupta art, for which, perhaps, the material was even more abundant than for Pal art.

Mr. A. L. Saunders, C.S.I., formerly Commissioner of Lucknow, said the only qualification he could possibly have for taking part in the discussion was his somewhat long service in an adjoining province, where artistic problems presented themselves from a somewhat different angle, which had been far better explained than he could hope to do by his colleague, Mr. Yusuf Ali. He would also like to express his agreement with Mr. Yusuf Ali when he referred to the great interest which the artistic history either of the Pal dynasty or any other period had in its bearings on the general and religious history of the same period. One so often got histories on one line alone, and the connexion between the two was not always brought out. That was particularly so with regard to the rise and fall of the Buddhist civilisation in India. One knew about the rise of that wonderful civilisation, and how it not only introduced new ideas but actually spread over the whole of Asia, even to the extent of exerting an influence over the Roman civilisation in Asia. What was involved in a haze of doubt and difficulty was why the civilisation having attained that point should have fallen and disappeared. Whether it was due to the Mohammedan invasion, or whether the Mohammedan invasion in turn was invited by the weakness of India it was not for him to say. There was, of course, the comparison with the decline of the Roman civilisation; but there it was more easily explained because of the altering of the balance of the population. The invaders of the Roman Empire were enormously superior in numbers to those of its inhabitants, but in the case of the Hindu civilisation it was different. It was perhaps a natural phenomenon; the rise, the decline, and the fall of a great civilisation. Mr. French had shown by reference to actual statues how the mentality of that civilisation might have varied in accordance with its art, and that was one of the most interesting of his explanations.

Sir Charles S. Bayley, G.C.I.E., K.C.S.I., said that after the remarks of Lord Ronaldshay, and the other exceedingly interesting speeches to which they had listened it would be almost wicked to interpose any remarks of his own; but he wished to express, on behalf of the Royal Society of Arts—he happened to be the Chairman of the Indian Section for the moment—and on behalf of the audience generally, their gratitude to Mr. French. It was obvious how greatly the paper had been appreciated by what might be called the more instructed part of the audience; but he (Sir Charles Bayley) wanted to speak on behalf of another section of the audience, namely, those who, although they had been in India for some time, were discreditably ignorant of Indian art, and had not the knowledge of Indian history which they would like to have. He was one of those, and if there were any others in his position he was sure they would feel as grateful to Mr. French as he did himself for what Mr. French had taught them. His address had been most valuable, and the value of it had already received the highest testimony that afternoon. He was sure that he was expressing the wish of the whole audience when he proposed a hearty vote of thanks to the author and to Lord Ronaldshay for taking the chair. No one could help realising what attention Lord Ronaldshay must have given during his Governorship, and probably at other times, to Indian affairs and to Indian art and Indian feeling. It was only necessary to have been present at the lecture which he gave the Society on "A Clash of Ideals as a Source of Indian Unrest" at the beginning of the previous year, to understand that very fully.

OBITUARY.

Sir George T. Beilby.

Sir George T. Beilby, F.R.S., LL.D., died on 31st July. By his death the Royal Society of Arts lost a member whose scientific work and industrial activities formed eminent contributions to the objects for which the Society exists, and whose devoted public service has been most fruitful in the local and national machinery for research and education in science and technology.

Sir George became a member of the Society in 1884 and as long ago as that year he read before its old "Applied Chemistry and Physics Section" a notable paper on "The Production of Ammonia from the Nitrogen of Minerals." On that occasion the late Sir William H. Perkin was in the chair—truly a notable conjunction of chemists who have broken new ground in the advance of chemical industries. In 1881 Sir George Beilby and his colleague Dr. James Young patented a retort which so greatly improved the appliances at the disposal of the Mineral Oil industry that its output of useful products steadily increased and it became one of the most flourishing of the industries of Central Scotland. Ten years later—to refer only to one of his major contributions to chemical industry—he introduced a method of producing cyanide, which in the hands of the Cassel Cyanide Company at Maryhill, Glasgow, increased immensely the production of the material essential for the recovery of gold by the cyanide process first practiced in New Zealand in 1889. His services in the promotion of Chemical Industries were no less productive in other departments for which he worked as Scientific Director of Chemical Works in this country and overseas.

He devoted much attention to problems bearing on fuel economy and smoke prevention in connexion with the coal consumption of Great Britain. He reported on this to the Royal Commission on Coal Supplies in 1903. In 1917 he was appointed Director of Fuel Research under the Department of Scientific and Industrial Research which had been established in 1916, Sir George Beilby being a member of the Advisory Council of the new department. From 1917 onwards, he made service in this outstanding public interest the first charge on his energies. Under his personal guidance and control a central Fuel Research station was erected at Greenwich by the Government. The series of important researches which have since been conducted there and in related laboratories, now constitute a body of ascertained facts and of proved methods of investigation which forms for further research a solid foundation and a system of well blazed tracks in the main directions of enquiry. Sir George Beilby's services to the country and to science in this matter extended over six years and they were entirely voluntary. In this respect they were on the same basis as those he gave to the Naval and Military Authorities during the war. He accepted no payment for services and he presented to the Government the rights in every patent he took out. A member of the Central Committee of the Admiralty Board of Inventions and Research and of the Trench and Chemical Warfare Research Committees he had been rendering continuous service to the prosecution of the war; the great value of his knowledge, skill and assiduity in these connexions is known only to those who had the good fortune to be associated with him in the team work of that period. Beilby's experience, judgment and resource were at the disposal of every colleague and his personality counted for a great deal in the grapple with difficulties, whether in matters of pure science or in the special field of developing from the results of scientific investigation practicable methods of production on the great scale required.

The last nine years of his life were indeed devoted gratuitously to national work in London, although for part of that time he was nominally resident in Glasgow. Before the War work which kept him so continuously in London, he had been an active citizen of the city which was the centre of his industrial activities. In particular he laboured for the great institution which is now the Royal Technical College. He was elected Chairman of the Governors of the College in 1907, and he spared no pains to secure for the College the co-operation of public authorities and institutions in Glasgow and the West of Scotland. His familiar acquaintance with the links between science, industry and commerce, and his fine personality were cogent aids in the steady advancement of the College as a centre of teaching and research.

Sir George Beilby received a knighthood in 1916. He was elected a fellow of the Royal Society in 1906. He was for several years a member of the Council of the Royal Society of Arts and he contributed £500 to the Society's Building Fund.

F.G.O.

CONFERENCE AT WEMBLEY ON ILLUMINATING ENGINEERING.

On August 12th, the Illuminating Engineering Society held a Conference at Wembley to discuss "The Best Means of Promoting Public Appreciation of the Benefits of Good Lighting." The subject was introduced by Mr. Leon Gaster, who has recently returned from Geneva, where he attended the International Conference on Industrial Hygiene, which took place under the auspices of the University of Geneva, and the International Illumination Commission Conference. A brief account was given of the work done at the above named Conferences and by the Illuminating Engineering Society. since its inception in this country, and by other illuminating engineering societies, In view of the large experience and information obtained during the last 18 years, it was felt that the time is now ripe to bring to the notice of the general public the advantages to be derived from good lighting, and the drawbacks of badly lighted factories, schools, etc. The conference was very well attended and fully representative. After an interesting discussion the following two resolutions were passed:

(1) "That, as a result of 18 years of experience of Illuminating Engineering in this country and the United States, this Conference considers that the time is ripe for a comprehensive effort to promote public appreciation of the benefits of good lighting, and views with approval the desire of the Illuminating Engineering Society to prepare a suitable scheme for this purpose, with the co-operation of other bodies interested in various aspects of illumination."

(2) "The Conference recommends that every support should be given by institutions for the encouragement of research, members of the public and by all sections of the lighting industry to the Illuminating Engineering Society in carrying out such a scheme."

The following papers were read and discussed at the Conference:—"The Illumination of Highways from the Motorists' point of view," by Mr. Edward H. Fryer (Head of the Road Dept., Automobile Association); "Some Notes on the Electric Lighting of the British Empire Exhibition," by Mr. Haydn T. Harrison; and "Some Notes on the Gas Lighting at the British Empire Exhibition," by Mr. G. L. Jennings (Brentford Gas Company).

LIVESTOCK INDUSTRY OF NORTHERN MANCHURIA.

A very small portion of the total resources of the livestock industry of northern Manchuria is being utilised at the present time. This is partly due to the fact that the important markets of Siberia are practically closed to trade. More than 50 per cent. of the meat trade of northern Manchuria is in the hands of a British firm, which maintains a modern packing plant at Harbin.

From a report by the United States Consul at Harbin it appears that the Kinghan Mountains form the border line between the barn-fed cattle industry and nomadic steppe herding. The entire territory from Tsitsikar to Harbin and Kwangchentze, on both sides of the Chinese Eastern Railway line, represents regions of farms with well-developed cereal culture and important trading centres. However, colonisation has not penetrated east of the Kinghan Mountains into what is known as the steppe country, with its enormous width and sparse population of nomadic tribes.

The principal centres for the trade in cattle are Hailar and Manchuria, although the place of the latter point is more and more being taken by Chalainor, which is only 19 miles distant and escapes the almost prohibitive taxes imposed in China. At these two points all of the more important cattle dealers maintain agents or branch offices. In the early spring these agents are supplied with silver cash, and they proceed into the plains country, where they close bargains directly with the owners of herds. By the middle of summer these cattle are driven to stations of the Chinese Eastern Railway and left to graze until the winter killing at local slaughterhouses. The carcasses are then shipped to the different markets or resold to merchants from the Maritime Province, Pri-Amur district, or Harbin. A total of 45,863 head was slaughtered during 1922 in northern Manchuria. However, this is small in comparison with the former times, during the imperial régime, when in Hailar alone 25,000 head were slaughtered annually, as against 4,000 at the present time. The best meat cattle come from the district south of Hailar, on the plains watered by the Kurlyn River. This region could easily supply 30,000 head of horned cattle and 500,000 sheep. During 1922 104,897 sheep were slaughtered in northern Manchuria, distributed as follows: 50,149 at Hailar, 24,324 at Manchuria, 1,247 at Tsitsikar, and 3,962 in other districts. During 1923 at Hailar alone 150,000 sheep were bought.

Hog raising takes first place among the industries of the densely populated districts of northern Manchuria. With the low price of cereals, hog raising has been found by the local Chinese and Russian farmers to be a profitable enterprise, and its development has kept step with the colonisation of the country. Therefore, the districts along the southern line of the Chinese Eastern Railway and the districts surrounding the city of Harbin are the centres of the industry. According to the economic bureau of the Chinese Eastern Railway, there are approximately 3,200,000 hogs in the Anda, Harbin, and southern districts.

The breeding of domestic pigs was begun very early in China (more than 3,000 years B.C.), but in spite of this and the fact that the industry has grown enormously, but little attention is paid to the improvement of breeds. However, the Chinese hog is remarkable for its fertility and early maturity. The methods of caring for and of fattening the hogs are very primitive, as is the mode of slaughtering, a large part of which is done on the farms.

The organisation of the hog buying is almost entirely in the hands of the Chinese merchants, who through their agents close bargains with the farmers and bring the animals to market. No reliable data are obtainable as to the number of hogs slaughtered, inasmuch as the majority of them are home killed, and are prepared on the farms. Public slaughter-houses kill on an average 900,000 animals yearly.

ELECTRIC POWER SCHEME IN MOROCCO.

In his annual report on the economic and commercial conditions in the French zone of Morocco, H.M. Consul at Casablanca states that during the past year a big "centrale thermique" has been and still is in course of construction just outside Casablanca. The owners, the Compagnie des Chemins de Fer du Maroc, are furnishing this power station with three turbo-alternators of 6,000 k.w. each or 18,000 kilowatts in all, with a 60,000-volts tension.

A general concession for the organisation of the production, transport and distribution of electrical energy in Morocco, granted under a law dated July 18th, 1923, is of "national" importance for Morocco and incidentally it embraces the Central Thermique of Casablanca mentioned above. A few details must suffice to indicate its great scope:

The concession is granted to the Banque de Paris et des Pays-Bas (acting in its own name and in the name of some twenty-four great French banking, electrical, railway and other enterprises) until the end of this century.

Its main objective as defined above is to be attained through:—

(*a*) The Casablanca Central Thermique.
(*b*) A first hydro-electric power station on the Oum-er-Rebia river, provision being made for a minimum of 5,000 kilowatts.
(*c*) A second hydraulic station, or a group of stations, to be constructed at some point or points to be determined in the upper basin of the Oum-er-Rebia
(*d*) Electric current for the electrification of (i) the Sidi-el-Aidi-Kouriga (Oued-Zem) to Casablanca phosphate railway; (ii) electrification of the broad gauge Rabat-Casablanca railway (now under construction) and the electricity needs of Rabat and Kenitra.
(*e*) (i) A transport line of electrical energy, in form of the letter Y, to join the Sidi Machou and Casablanca stations with a branch through Azemmour to Mazagan; (ii) the same between Sidi Machou and Sidi-el-Aidi.
(*f*) A line of current to electrify the railway between Sidi-el-Aidi and Marrakesh, and supply electricity to Settat and Marrakesh.
(*g*) Lines between the power station on the upper and lower Oum-er-Rebia river
(*h*) Any further secondary lines found to be necessary.

Part of this programme has no date fixed for completion, but the Casablanca power station was to be completed by July 1st, 1924, and the Sidi Machou station by the end of 1927.

The concession is criticised as providing for needs not likely to become pressing for the inhabitants for many years; on the other hand it is argued that, in the absence of coal and petrol, Morocco must be provided with a local source of power always to hand and procurable at a price fixed by herself. The subsequent development of the country will prove which of these two schools of thought is correct.

Small electric stations are being erected in certain of the towns, and Mazagan and Saffi already and Marrakesh this year will be provided with power sufficient for all lighting and moderate industrial needs.

MINERAL WEALTH OF THE FRENCH ZONE OF MOROCCO.

So far as is known at present, writes H.M. Consul at Casablanca, the great subsoil wealth of Morocco lies in its limitless phosphate beds. The only group of beds at present exploited stretch over an area of 80 by 50 kilometres around El Bouroudj, and the product is now averaging 74.80 per cent. phosphate of lime. The output from nil, in 1920, rose to 190,000 tons in 1923, and the estimate for 1924 is 350,000 tons, with an annual growth of 150,000 tons for some years to come. A broad gauge railway now joins the chief extraction centre to the quays of Casablanca, where the phosphates can be loaded by special machinery at the rate of 300 tons per hour.

As regards secondary minerals, the principal deposits so far located are :—

(i) Manganese—South of Oudjda.
(ii) Manganese and lead—North-west of Figuig.
(iii) Tin—Oulmes district.
(iv) Iron—Camp Boulhaut and Sokhrat-el-Djaja.
(v) Gold and silver—Moulay-bou-Azza.
(vi) Lead—The Rehamna.
(vii) Lead and copper—the Zaer region.

Further small quantities of iron have been traced in the Djebel Haddid and of copper to the south of Marrakesh, where incidentally a gold mine is being exploited. As regards fuel, only insignificant traces of coal have been found hitherto, while borings for petroleum, which have been carried out fairly extensively, have given unsatisfactory results, though hope of remunerative discoveries is not yet abandoned.

THE CITRIC ACID INDUSTRY OF ITALY.

The Italian citric acid industry during recent years has developed to considerable proportions. Italy, more especially Sicily, has always had practically a world monopoly in connexion with the production of calcium citrate. From 1908 to 1910 the annual Italian output amounted to about 6,000 metric tons. From 1918 to 1920 it rose approximately to 8,500 tons. It is estimated that during the last few years production has approximated 8,000 tons yearly. Although other countries, namely the Dominican Republic, Spain, and the British West Indies, as well as California, are producing fair quantities of calcium citrate, the Sicilian industry continues to account for nine tenths of the world output.

From a report by the United States Trade Commissioner at Rome, it appears that the first plant which made a real success in producing citric acid in Sicily was the Fabbrica Chimica Arenella, a subsidiary of the Societé Anonima Chimica Italiana Godemberg, in turn an affiliation of the Chemische Fabrik Godemberg of Wiesbaden (Germany). The German company sent 15 of its best workers to the plant at Palermo and gradually obtained good results. In the year 1913-14 a production of about 1,000 tons of citric acid was reached. In 1916 the Fabbrica Chimica Arenella was freed from its foreign connexions and is to-day the largest citric acid producer in the world. The number of workers employed is about 450, and it has a capacity of from 2,500 to 3,000 tons per annum of calcium citrate—about one-third of the entire production of Sicily—from which 1,500 to 2,000 tons of citric acid are obtained. Besides this company two others have been organised in recent years and another is at present under construction. All three are located in the Province of Messina and are able to transform 5,500 tons of calcium citrate per annum.

If to these 5,500 tons be added the 2,500 tons output of the Arenella Co., a total of 8,000 metric tons, approximating Sicily's total annual production of calcium citrate, is obtained. This industry has come to the front in the course of a very few years and has had a growth which might, perhaps, even be considered too rapid.

Besides the Sicilian industry there is also the Societé Anonima L'Appula, which has plants in Italy proper, at Vercelli and Linate, whose combined output of citric acid for the year 1922 reached 447 metric tons. These two plants, however, are capable of producing as much as 1,200 tons per annum.

RESOURCES OF THE SPANISH ZONE OF MOROCCO.

In reporting on the trade and commerce of the Spanish Zone of Morocco, Mr. C. A. Were, late H.M. Vice-Consul at Tetuan, writes that the trade and commerce of the country are still in a very undeveloped and unsatisfactory state. It is true that its possibilities are at best restricted, but little or nothing has been done to develop available resources, while in some instances existing industries have fallen off in production or even ceased to exist. There are, indeed, no organised industries in existence at present, and when it is added that the agricultural produce of the country is for the moment insufficient for its own needs, and that its potential mineral wealth has been exploited only on a small scale, it will be readily understood that its exports are insignificant.

Agriculture.—The zone is never likely to become more than self-supporting in this respect, owing to the unsuitable nature of the greater part of its soil and the abundance of palmetto, the extirpation of which is an exceedingly tedious and costly business. Exceptions are the plain of Rio Martin and, in particular, the territory of the Khlot, near Alcazar, where exceedingly fine crops of cereals are produced.

Stock-breeding.—The breeding of stock should, if systematically organised and directed, be of great value to the zone. Most of the land, unsuitable for various reasons for agricultural purposes, provides excellent grazing. Even at the present time the cattle, sheep, pigs, etc., to be seen in the zone are remarkably healthy, though on the small side. The state of insecurity still prevailing in many districts, however, is a serious obstacle, and it is only in the vicinity of the towns that cattle can be pastured without fear of robbery.

Minerals.—Great hopes of the presence in the Riff and elsewhere of large and commercially workable mineral deposits have for long been entertained, and the Department of Overseas Trade is in possession of a list, compiled by the late Mr. Vice-Consul Atkinson from native sources of information, of such deposits, with their approximate situation as described to him. There is every reason to suppose that the information contained therein is ampler and more correct than that gathered by the various mining engineers and prospectors who have ventured into the Riff. Owing to the permanent unrest prevailing in that country it is only by favour of the Riffian leader that the supposed mineral deposits can be visited, and he is chary of granting permission, being distrustful of Europeans in general, and anxious to obtain substantial pecuniary remuneration before permitting even investigation. It appears, therefore, that the investigation (leaving out of account the exploitation) of the mineral resources of the Riff must be postponed either until the Riffian chieftain has acquired a greater insight into European methods of business, or until the protecting power has entirely subjugated the district. Either process will absorb much time. Apart from the Riff deposits, two iron-ore mines are being worked, with fair success, in the Melilla district, by Spanish companies, and a Spanish company has made various attempts to extract tin and other minerals in the vicinty of Tetuan, with meagre results.

HARBOUR WORKS IN MOROCCO.

The port of Casablanca has been the greatest public work carried out by the French in Morocco. The port commenced in 1913, by the firm of Schneider et Cie, is now approaching completion in its most arduous part. The massive grand jetty, which is to extend for 2,050 metres, is nearly finished, while the Transversal jetty has advanced over 860 metres out of the 1,600 metres of its projected length. Already the 150 acres of water space are fully protected in all weathers. Two to three steamers can now lie alongside the grand jetty simultaneously and passengers be landed direct on to the quay.

According to the survey of economic and commercial conditions in the French zone of Morocco by H.M. Consul at Casablanca, supplementary docks and wharves are to be built later, and the equipment will be sufficient to handle 1,500,000 tons of merchandise per annum, exclusive of phosphates. The 1923 figures, including phosphates (190,000 tons), gave a total of 680,000 tons handled in the port.

The port of Saffi—for lighters—was commenced in 1923, and work is proceeding actively on the port at the mouth of the Bou Regreg—the port of Rabat-Sallee.

At Fedhala, where a small lighter port has been constructed, there is a scheme to continue construction and equip the harbour as the oil fuel port of Morocco, and it is believed the necessary steps will be taken shortly.

Work is also proceeding in the small Mazagan port. Finally Agadir, the southernmost port of Morocco, is being equipped with a lighterage harbour.

The opening of Agadir to commerce will, it is feared, affect the prosperity of Mogador, as the Sous or district south of the Atlas is at present supplied through Mogador.

The policy of spending so much money (including Mehedia-Kenitra in the north) on a row of seven small Atlantic ports, in addition to the immense work undertaken at Casablanca, is declared in many quarters to be unnecessary and extravagant, in view of the modest maximum yield that Morocco can render for many years to come.

GENERAL NOTE.

Institute of Metals.—The Autumn Meeting of the Institute of Metals will be held in London from September 8th to 11th. The third annual Autumn Lecture will be delivered on the former day by Mr. W. M. Corse, S.B., of the National Research Council, Washington, U.S.A., the subject being "Recent Developments in Non-Ferrous Metallurgy in the United States, with Special Reference to Nickel and Aluminium-Bronze." Amongst the communications expected to be submitted are the following:—"A Method for Measuring Internal Stress in Brass Tubes," by Robert J. Anderson, B.S. (Boston, Mass., U.S.A.) and Everett G. Fahlman, B.S. (Cleveland, O., U.S.A.); "Seventh Report to the Corrosion Research Committee of the Institute of Metals," by Guy D. Bengough, M.A., D.Sc. and R. May, A.R.S.M. (London); "Investigation of the Effects of Impurities on Copper. Part II.—The Effect of Iron on Copper," by D. Hanson, D.Sc. and Grace W. Ford, B.Sc. (Teddington); "Experiments on the Working of Nickel for Coinage," by Sir Thomas K. Rose, D.Sc., A.R.S.M., and J. H. Watson, M.C., B.Sc., A.R.S.M. (London); "Studies in the Aluminium-Zinc System," by Tomojiro Tanabe (Osaka, Japan); and "Metal Spraying and Sprayed Metal," by T. Henry Turner, M.Sc., and W. E. Ballard (Birmingham).

Journal of the Royal Society of Arts.

No. 3,745. VOL. LXXII.

FRIDAY, AUGUST 29, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.2.

SEP 1924

PROCEEDINGS OF THE SOCIETY.

◆

DOMINIONS AND COLONIES SECTION.

THURSDAY, JULY 24TH, 1924.

THE HON. W. G. A. ORMSBY-GORE, M.P., late Under-Secretary of State for the Colonies, in the chair.

THE CHAIRMAN said the Royal Society of Arts and the audience were deeply indebted to M. Franck for attending that afternoon to deliver a lecture on "Recent Developments in the Belgian Congo," and his ideas of the future of that territory. It was a matter of great interest to a British audience. M. Franck was Belgian Minister of the Colonies from 1918 to 1924. Before 1918, he had languished for a certain time in a German prison for patriotically maintaining the rights of his fellow-countrymen, for which he had our double regard as an Ally. Not only had M. Franck been Minister of the Colonies in his own country, but he had twice visited the Congo, on one occasion going through to the East Coast of Africa.

He (the Chairman) was personally interested in the subject of the lecture, as the British Government was sending him out shortly as Chairman of a Commission to the Tanganyika Territory, Uganda, and the other British Dependencies in East Africa. The great problems of transportation, public health and increased production which M. Franck and his country had before them were in a way peculiarly their own, and included the development of what was probably the largest and most valuable copper-field in the world, Katanga, which, now in its infancy, was destined to play a big part in the future of Tropical Africa as a whole.

The paper read was:—

RECENT DEVELOPMENTS IN THE BELGIAN CONGO.

By LOUIS FRANCK, G.C.V.O.

(Late Colonial Minister of Belgium.)

What are the problems of the Congo? They may be summarised in two words: transportation and population.

By its very nature, Central Africa, which is a sort of enormous flat cup rising high above the sea-level, has a splendid system of waterways. But this system has a great drawback; it is cut off from the seas and barred in various places by falls and rapids.

Only the modern mechanical means of carriage can supplement this deficiency of nature.

After travelling all over the country, Stanley put the matter in a nutshell:—"Without railways, the Congo is not worth a shilling." But even an adequate system of conveyance and carriage will not develop the enormous country without a numerous, healthy and efficient population.

PROBLEMS OF TRANSPORT.

Transport is the chief instrument of colonisation. What had we done, in this direction, before the war?

1. *Railways.*—The first railway which the Belgians built has been a pioneer work. As early as May 1898 they completed a railway of 400 kilometres, connecting the deep water port of Matadi, on the Lower Congo, with Stanley Pool, where the Middle Congo becomes navigable for more than 1,800 kilometres up to the Stanley Falls.

It was a most difficult and arduous task, but the barrier of the mountains, which had so long isolated Central Africa, was broken, and broken for the first time.

Then a concession was granted for railways which, in the centre of the Colony, above the Stanley Falls, would double the river in those places where, owing to cataracts, it was not navigable. The railway was successively laid from Stanleyville to Ponthierville, and from Kindu to Kongolo, thus connecting the Upper Congo or Lualaba with the Middle Congo, just as the latter had been connected with the lower river by the Matadi-Leopoldville railway.

The newly discovered importance of the Katanga as a great mineral centre made it necessary to connect the Katanga with the railway system of South Africa, which was done at that time, up to Kambove. During the war, this line was continued to Bukama, another line being completed between the higher Congo River and Lake

Tanganyika, from Kabalo to Albertville. These lines were absolutely necessary for the supply of our brave native troops who defeated the Germans, conquered Ruanda, Urundi and the whole country up to Kigoma and Tabora, and whose victorious and rapid blows had a decisive influence on the issue of the contest in that part of the world.

After the war it became clear that the system of railways as existing then was incomplete and inadequate.

It was first necessary to considerably develop the Katanga railways, as far as plant, organisation and rolling-stock were concerned. No less than 150 million francs were spent after 1918 with that object. Thanks to these improvements the Katanga railways are able to-day to face a traffic of more than 3,000,000 tons.

The pioneer line of Matadi-Leopoldville had become obsolete: its very small gauge (72 centimetre) chiefly attracted attention, but its real drawbacks were the stiff gradients and the short curves. A new line, new for two thirds of the distance, was mapped out, the building of which has begun. It has further been decided that the railway shall be electrified and the gauge widened to 1.067 metre, the usual African gauge. This transformation will considerably increase the carrying capacity of the railway and meet any extension of traffic which can be foreseen. The amount involved is at least 200 million francs.

But I had to take a much more important resolution. A glance at the map will show that it is an absolute necessity to link up the mining district of Katanga with the Atlantic. There was an old scheme involving the building of a railway over the whole distance from Katanga to Stanley Pool. At post-war prices, this scheme meant such a large outlay, owing to the long mileage and the very difficult country after crossing the Kasai River at Djoko-Purida, that its cost would have been prohibitive, and the railway would not have been able to compete with other lines, existing, planned, or under construction. I, therefore, took the decision to link 750 kilometres good waterway to the railway system. Water transport means a reduction from 3 to 1 in cost as compared with railway carriage; the drawback of transhipment is immaterial in the case of copper and the other raw material to be considered in that part of the colony. The length of railway to be built was consequently reduced, and the cost of exploitation also. Furthermore, the country chosen for the new scheme is much richer and it is very likely that the line will be a paying concern on the whole distance.

This railway—the Bukama-Ilebo—is in full construction. The first survey was ordered in August, 1921, the distance being more than a thousand kilometres. The actual construction was begun in March, 1923. Before the end of this year, more than one third of the line will be built, and it is expected that 1925 and 1926 will see the building of most of the remaining part; so that in 1927, if all goes well, the first trains will bring the copper from the Katanga and the cotton from the Sankuru district direct to the Kasai river, whence they will proceed by river craft to Stanley Pool and by the Congo railway to the seaport of Matadi. The cost will be from 350 to 400 million francs.

In the north-east corner of the colony, near to Lake Albert and the Sudan, we have an interesting gold mining territory known as the Kilo and Moto mines. We have resolved to link it by rail with the Middle Congo, thereby opening up extensive and valuable country for over 1,000 kilometres, and connecting the south of the colony with the north, just as the Bukama-Ilebo railway connects the south with the west. This railway scheme is at present under survey and will be extended later on to Lake Albert, by that means joining the Congo with the Nile!

At the same time several small gauge railways of about 200 to 250 kilometres are being built in the Uele district, and will bring the navigable parts of the Itimbiri and Uele rivers in communication. This extension will also open up a very rich country, hitherto hampered by lack of transport.

The total length of these new Congo railways, undertaken since the armistice—they are not merely schemes, but actually in process of construction—is between 2,700 and 2,800 kilometres. As the Belgian railway system is only 3,200 kilometres in length, and as there are already about 2,000 kilometres of railways in the Colony, you will agree that Belgium is not lacking in active help towards the development of its African possessions, especially when you consider how heavily our finances have been handicapped by the war and the non-payment of our claims on Germany.

I have only spoken of those railways which we are building at present. I purposely abstain from mentioning other interesting schemes, the importance of which I do not however underrate.

The reason is, that even without considering finance, there is a factor of paramount importance which in a country like the Congo you must on no account ignore, namely, native labour and the native labourer. All this huge railway building finally rests on the number of natives you can spare from the kraals, the fields, the fishing, and the hunting grounds. As a rule, the native, if you respect his free-will—as we absolutely and unconditionally want to do—will only engage his services for a limited term, say six months or a year. This means that for every man on the works, there is one returning home or just returned, and one on his way to engage in his turn. Now the Congo native has been made to understand that the railways are going to deliver him from the portage, which is a plague to Central Africa. He does not grumble at the work, if decently fed, paid and treated, but it is easy to understand that there is a limit which you may not transgress if you are not going to bring untold hardships on the population and excite their anger against the railway-work and the white man's enterprise.

2. *Ports and Rivers.*—Next to the railways, and in connexion with them, we are building new river ports or extending old ones: Kinshasa, on Stanley Pool, Ilebo on the Kasai, Matadi on the Lower Congo. The equipment of the rivers is a big affair. Within three years a considerable number of barges will have to be built in Europe, carried in pieces to Matadi and up the railway to Stanley Pool, and put together there in order to meet the traffic which will at the end of that term begin to roll down from the Katanga.

Naturally, a good deal of it will still go south, but the part which will come north will mean a great effort to equip the waterways with suitable craft.

3. *Roads and Motor Transport.*—In our plans of development, roads and motor transport are not lost sight of. Our last achievement has been to build the missing link in the Cairo to Cape route. The main road connecting Nyangara with Redjaf in the Sudan was completed a few months ago and equipped with motor cars.

Do tourists realise what all this development means to them? Travellers may now start from Cape Town, and, by modern mechanical means of transport, railways, steamers, and motor cars, reach Cairo without any undue exertion or risk. You may by similar means cross Africa from Dar-es-Salaam on the Indian Ocean and within six weeks reach Matadi on the Atlantic.

A four months' holiday will take you comfortably, with reasonable time for sight-seeing, from London to the Cape, thence through South Africa and along the whole Congo rivers to Matadi and thence back to Europe. No longer time would be required for the Cape-Cairo trip. But when this is said, I am bound to add that our experience is that however useful roads and motors may be for administration and travelling and also for tapping the country to feed railways and steamers, they cannot and will not develop a country like Central Africa. The reason is simple: the cost of a kilometric ton per motor lorry varies from 4 to 10 and 12 francs, which is prohibitive.

I may have dwelt a little too long on the problem of communications in Congo. There is nothing in it that you have not done on a much bigger scale in your splendid colonial Empire. My only object has been to show that to the best of our ability we are doing what is necessary to further open up the country, and I may perhaps add that we give all honest trade a fair and equal chance. The best proof is that on a total import into the colony in 1921 and 1922 of between 231,482,870 and 276,027,218 francs in value, the Belgian produce amounted to scarcely 50%. We hope to do better in future, but the figures are certainly a proof of fair play and free trade,

I now turn to the other problem which is dominating all colonisation in Central Africa. This is population.

PROBLEMS OF POPULATION.

The Congo has an area of about 910,000 square miles.

But what is the population? In a space corresponding to that where at least a hundred and fifty million people are living in Europe, and perhaps two hundred and fifty millions in parts of India and China, there are no more than twelve millions of human beings in Central Africa. And yet, with the exception of Nigeria, the Congo is more thickly populated than any of the other colonies of Tropical Africa. What are the reasons for this thin population?

General Conditions of Life.—There is a certain picture of the life of primitive mankind. Poets and novelists and some social reformers have seen it as that of simple folk, with modest tastes and no ambition, living quietly and happily on the natural products which the glorious sun and the fertile land supply with lavish generosity, and practically without pain or labour. It is a paradisiacal country and a paradisiacal life; the only trouble comes from the white man and his restless ambition and greed. That is the picture. But the truth is quite different. Insufficiently supplied with food, with scarcely any clothes, badly housed, the African native is living in very poor conditions and he is an easy prey to terrible diseases, which are rampant everywhere in the Tropics. These bad physical conditions keep the population down in Africa, as similar conditions have done for centuries in most parts of the world. Now, without a much more numerous population, living in healthy conditions and with a better economical standard, there is no future for Central Africa. As we want it to have a great future and believe in it, we were bound to tackle the problem, and just as we provide railways and ports and ships, we must build the race up anew and procure better hygienic, moral and economical conditions of life, for our black subjects: that is the mandate and the trust we are under. It is a great battle but one well deserving to be waged and won. We do not underrate the difficulties. "To raise the native from the low state of civilisation in which he at present exists," says the Admiralty Manual on Belgian Congo, p. 10, "to educate him, and to improve his moral and social outlook will be a task of the greatest difficulty." It is a problem of hygiene and morality.

Sleeping Sickness.—From a sanitary point of view, the chief enemy of our natives is trypanosomiasis or sleeping sickness. As every one knows, sleeping sickness is a disease caused by microbes which are conveyed by a fly; *Glossina palpalis* or *morsitans* is the scientific name, *tsetse* is the vulgar one. The fly sucks the parasites from the blood of infected people and goes on infecting others. So the three actors in the drama are the parasite, the fly, the infected person. The disease, if treated early, is now considered to be curable. But how to discover it rapidly and efficiently or how to prevent it from spreading? Amongst the natives, it has wrought terrible havoc.

The infection is not general in the country. Many areas are not touched by it; in others it has lately abated; generally speaking, it appears rather stationary than increasing. Nevertheless, it remains a terrible plague.

For the European, wearing clothes and using care, there is no serious risk; the number of such cases is very small, and as the patients are regularly treated in time, they are very generally cured.

But with the natives the position is quite different.

The fly seeks for water and shade; so it keeps to the lakes and rivers, just where the population likes to dwell.

In order to fight the plague, various systems have been tried—segregation and medical treatment of the infected people; transfer of the villages away from the side of the water; cutting down vegetation; controlling the native travellers; there is much good in any one of these measures but none has proved really efficient.

We are, and have been for four or five years, resorting to a system of powerfully-equipped medical missions, operating in the more infected regions, and trying to "clean" the whole of the population, so that the fly can no longer infect itself by biting infected persons.

In individual cases, microscopic observation of the blood is the natural way of detecting the disease. But for mass treatment, in parts of the country where the disease is found to be strongly prevalent, the diagnosis is generally limited to such exterior symptoms as enlargement of the glands of the neck. This-rough-and-ready method alone permits the work to be carried out on a huge scale and with the necessary diligence.

These medical missions proceed methodically from village to village and territory to territory, examine all natives, treat all who are infected or suspect, keep a census of the people examined and treated, and as they advance they leave behind them trained native injectors, who continue the treatment. Second and third examinations are made at intervals. It is an enormous undertaking. In four years, in the Kwango and Kasai districts, 3,272 villages have been treated, 534,323 natives examined, and 850,000 injections given. Consider what this means in a difficult, wooded and mountainous country, with a population, ignorant and, at least at the beginning, objecting to the treatment. But consider also the results.

At the first examination, in one of the areas, for instance, the number of sick persons was 16.3 per hundred of the population; at the second examination, it had fallen 6·2%, at the third to 2.2%. Another territory gives the following percentages: 9.5% at the start, 6.5 % at the second visit, 2.2% at the third. On the average, one may say, there has been a gain of from 3 to 1 and that by continuing the system, the disease can be successfully fought.

As to the therapeutic means which are available, you all know that no absolute remedy has been discovered up to date. The usual products injected are atoxyl and emetic. A new Bayer product, No. 205, has been tried by us with success. Its action is more permanent than that of other remedies and it seems to require a less number of injections, an important advantage. An American remedy prepared by the Rockefeller Institute, has been experimented upon at Kinshasa by a distinguished American lady scientist, Dr. Pearce, and is still on trial in our Congo laboratories.

Other Tropical Diseases.—Sleeping sickness is by no means the only important disease which threatens the black man; malaria is a terrible visitation, as also are pneumonia, syphilis, framboesia, etc.

But the greatest drawback, from a sanitary point of view, is the lack of natural resistance of the native to all sorts of sickness, owing to ignorance, neglect of general precautions and backward economical conditions. The children especially pay a heavy toll to pneumonia, as the native mother, although very loving and kind, takes no measures against the low temperature at night and at the beginning of the day. What is the remedy for this terrible infantile mortality? Where white women live, in our cities, and at the missions, they are trying to educate the native mothers. The work is excellent, but is as a drop of water in the sea.

Medical Organisation.—Doctors are the backbone of any hygienic system. Their number in the colony has been largely increased. In 1918, when I took office, the number in State service was only 39. In the last budget provision is made for 126. There were no trained nurses except the very devoted Catholic sisters. These have much increased in number, and there are at present 25 trained nurses, who specially attend to the care of children. Hospitals and dispensaries are numerous. The great industrial and plantation companies are obliged, by the conditions of their concessions, to have a medical staff, and a few months ago, M. Malan, Minister of Agriculture of the Union, after visiting Katanga, paid a warm tribute to the hospital organisation, the native camps and sanitary arrangements in the mining district. He said that the organisation in the factories, for which the Union Minière is responsible, was not inferior to that of the Rand. The Missions do much valuable work in the same direction. But when one considers the extent of the country and the ignorance and prejudice of the illiterate native, it is clear that additional measures had to be found. After carefully studying the problem with our medical staff, during my inspection journey through the Congo, Kenya, and Uganda, I came to the conclusion that the native himself ought to be enlisted in this battle for better hygienic conditions and that the practice of the medical profession in the Congo ought to be industrialised to a large extent.

Schools for Native Medical Assistants.—It was, therefore, decided to create in different parts of the colony, six schools for the training of native medical assistants. These six schools are at work. They give a three years' course, chiefly practical, and they limit themselves mainly to the classical treatment of five or six of the principal diseases, prevalent in the Congo, to elementary hygiene and small surgery. The intention is that these coloured medical assistants shall work under the supervision of the white doctor or at least of the administrator, or the missionaries. There are some difficulties in the way of recruiting a good class of pupils, but the natives seem eager to take up this career; the "medicine man" has always been greatly honoured in the African village. We have also increased and continue to increase the white staff of the European doctor,—trained nurses and male sanitary assistants. With the same object in view I obtained power from Parliament to the effect that the young priests preparing for missionary work and subject to conscription should be put at the disposal of the Ministry of the Colonies for military training and service. I organised this military service for the colonies on a medical basis; there is no more efficient warfare in Central Africa than fighting tropical diseases. The young gentlemen referred to are getting at one of our

Universities a year's course of medical training, in view of their future activity in the tropics.

The final object of all these reforms and developments is that the doctor shall no longer be compelled to work alone and individually as in Europe, but be in command of a numerous group of white and black helpers, chiefly the latter, who may extend and multiply his action. Our medical methods in such a primitive country do not aim at perfection, but at obtaining with the available means as much efficiency as possible. This cannot be done except by organisation. Thus we are building up gradually a system by which the European doctors will be the officers of a sanitary army in which black medical soldiers will play an important rôle.

The native medical schools have another and more general merit. Rational and sound ideas of sanitation and hygiene will penetrate more easily into the natives' mind if they come to them from men of their own race, and we hope that eventually the Congo will see the end of the witch doctor, who is doing so much harm. At present the native in the Congo does not believe in the natural cause of diseases. All are to him the work of evil spirits. Well, these young medical students see the evil spirit under their microscope; they know that quinine or atoxyl kills it, and that incantations and witchcraft will not, and so—at least on this limited ground—something will have been done to build a bridge between the European mind and the black mentality.

This leads me to say a few words on our views of the education of the black man.

Education.—We believe in education. We do not believe in Europeanisation.

At an earlier period, we were eager to think that our primitive African subjects were likely to understand and accept our abstract intellectuality, our respect for logic, our belief in progress, justice and liberty, and that they would admire the indomitable energy and activity of the white man. They do not. They ignore abstract ideas and principles; they live among positive, concrete facts, but they entirely transform them by their unbounded imagination. The shadow they see, or think they see, the dead they have lost, the big rock which bars their path, the tree which falls, the leopard which kills a man, have all a spiritual force within them and this force is to the native mind a concrete reality, a sort of living being or force with hatred and love, of which due account is to be taken if it is not going to bring you damage, disease and death. What sort of dialectics this turn of mind is leading to may well be illustrated by a quite recent instance. When, a few years ago, the two first aeroplanes of the King Albert line between Stanley Pool and the Stanley Falls came down at Gombe, the natives made up their minds that one was a male and the other a female, and they showed our officers which was the male bird and which the female. Their reason appeared to be that the male had come down first, seeking a way for his wife, as some birds will do, or as the native might himself do in an unknown country. So the modern flying machine had acquired a soul and a spirit, and habits and ideas of the animal species to which it was considered to belong. By a mere effect of imagination a mental comparison or image had quickly grown into an objective reality. Many other instances might be given, and the position is in no sense peculiar to our African population.

It is because the difference in mentality is so great that the problem of education in the Congo is so difficult. To simply import our European school system, our European text-books, languages and ideas, must necessarily lead to waste of time and labour, to anarchy and discontent. We might rely on the natural spirit of imitation in the black man and aim at assimilation; but we think that in so doing we should only manufacture third class copies of Europeans. We wish instead to try to make a better African, stronger, more efficient, of a higher morality. But that we can only do if our educational system is adapted to his mentality; if its aim is to develop him and not imitation of us, if it seeks its basis in the character, nature and traditions of the native. To that effect technical, manual and agricultural education in the native languages seems to be the right system. Respect of the native institutions is a natural corollary to that education and has become the very basis of our policy.

Native Institutions.—We find that the white man has often a natural impatience with some customs of the negro which although not cruel or inhuman hurt our feelings; it is very simple to call them barbarous and make a clean sweep of the thing.

But these primitive folk have rights of their own; they have their view of life and family organisation; we may and must induce them to correct what is wrong; but it would be hard, unfair and dangerous to do this at once, by legislation or by brutal and drastic interference. We think that we must leave things to gradually develop, and in that way build up an African civilisation.

A very striking example of the good results which may be achieved by respecting native institutions is supplied by Ruanda and Urundi, the two mandate territories entrusted to our care.

Whereas in many parts of the Congo colony, the big chiefs have formerly, and not without reasonable motives (such as rebellion) been removed and their dominions often divided up between their sons or other chiefs, in Ruanda and Urundi we made it from the beginning our guiding principle to maintain the existing political organisation and to rule through the two native sultans. The Watuzi, the dominant class, were kept in possession and power, but the exactions and abuses under which the subject race was often labouring were suppressed. In both principalities we have rather strengthened the central power.

The results of this policy are very good! The country develops well and has a bright future before it. The generous, and I may say gentlemanlike, way in which Great Britain settled the boundary question along the river Kagera has done very much to increase the prestige of the white man. We made it clear to the native rulers that the matter could only be settled on grounds of justice and fairness. They were polite but very sceptical. I quite remember the attitude of King Musinga when I tried personally, in his *Boma*, at Nyanza, to explain the position to him: our friendship and alliance with Great Britain, the impossibility of a conflict, your love of fairness and equity. He said:—

" But, Boula Matari, you say you love me and my family and my people and want us not to be deprived of the land of our ancestors."

" Yes, this is what I say and think."

" Well, you have fought and beaten the Germans?"

" Yes."

" Why, if you love us, don't you fight and beat the English?"

But at present, when the Kisaka region, after having been given up, has been returned to Ruanda, King Musinga and the elders said: "Yes, we see that the white men love justice and listen to reason."

The Chairman (Mr. Ormsby-Gore) has had a most honourable part in this arrangement and, may perhaps feel as I do, that this appreciation by that native ruler far away at Nyanza, in his mountains of Ruanda, is well worth remembering and that politics have not often in store for us prizes of such moral value.

In the Congo proper, we are following at present the same methods. Great care is taken to respect tribal life, native institutions, native chiefs; to organise native tribunals and councils; to educate native clerks; to get under all forms native co-operation for the administration of the country. And this method works very well.

I have thus outlined our general policy for the development of the Congo and now you may well ask two questions: first, what progress is being made; secondly, is the colony paying or at least self supporting?

What Progress is being Made?

The first and most considerable progress is that peace, order and security are reigning from the Atlantic to Lake Tanganyika and from Rhodesia to the Sudan. To appreciate what that means to Africa, let one remember that the Arab slave traders were carrying their horrible raids into the heart of the Congo as late as the beginning of the nineties. To annihilate their domination took several years of hard and dangerous war. The difficulty and merits of the Arab campaign are not known enough abroad. The Belgian officers in that war may justly claim a great share of the blessings which Livingstone in his last words promised to those who would save Africa from the curse of slavery.

The native is slowly beginning to enjoy individual freedom; he is able to move from one part of the country to another without being captured by hostile tribes and reduced to slavery. Domestic slavery is rapidly disappearing, as it is under no form recognised by us and as the European establishments and factories supply a living and freedom to the domestic slave who wants to leave his master. The liquor traffic is strictly forbidden. The native has learned the use of money, which in a few years has spread wonderfully. Labour in the mines and factories is becoming more popular as care for the welfare of and food for the native labourer increases. The Union Minière, for instance, had formerly to recruit or import all their labour; to-day nearly 35 per cent. of their black workers are voluntarily presenting themselves, as Europeans would do. The *Forminière*, the diamond company, has had a not less favourable experience. Many natives are becoming small traders in European wares and are doing well. All this means a marked economical progress, but the moral advance is slow.

Moral progress is greatly helped by the admirable mission work which is done by the two Christian Churches on a large scale and in the most generous spirit. Our experience is that the Congo native is an essentially religious being. His intellectual life is enveloped in mystery. Under European influence much of this will go, but nothing good will result if no new creed of superior moral value takes the place of the old belief.

The further development of the country is likely to considerably improve the standard of life of the population and render possible a better family life, although, as everywhere else, the first decades of contact between two civilisations so widely different are meaning great risks to the inferior race; to this, the moral state of the big black settlements near European towns is a sad proof. But with a second generation and better adaptation, progress may be expected.

The economical evolution of the country is therefore very important for the future of the native population.

What are the chief features of this evolution?

The first exports from the Congo were simply the raw produce of the forest or the hunting ground: rubber and ivory.

Some plantations of cacao and coffee have been created. Rubber has also been planted. But it will remain the honour of a great British firm to have started the first really important enterprise based on cultivation and industrial organisation. Messrs. Lever Brothers, in creating the Huileries du Congo Belge, have given the commerce and industry of palm kernels and palm oil such a development that these branches have become the backbone of Congo vegetal exports.

The colony is second only to Nigeria in these respects.

The export of copal, a gum which is employed in the manufacture of varnish, which was only about a thousand tons in 1910, is to-day averaging from 12,000 to 14,000 tons. Cotton was introduced a few years ago by the Government and is a great success. Lack of modern communications and the demand for labour by the new railways are hampering the extension of this industry, but no doubt it will increase very rapidly when the new system of railways is ready. Length and quality of the fibre are good; several ginneries have been established and the native likes to plant cotton.

As to administrative survey and co-operation, we have taken as an example the excellent system which I saw at work in Uganda.

Important plantations of cotton can be established in the country which the new railway—Bukama-Ilebo—is traversing; the combination of copper and cotton may prove very favourable freight both for railways and steamers.

Other efforts have been made to improve and increase the cultivation of the land, especially by the native in and around his village. However, most of the agricultural work is still to be done. The object is not neglected, but it is natural that in an industrial country like Belgium the mineral wealth of the Colony should have first attracted attention.

From the mineral point of view, the history of the Congo is like a fairy tale. When, in April, 1908, I spoke in Parliament in favour of the annexation of the Congo, the *Times* correspondent wrote:

"M. Franck gave a glowing description of the potential wealth of the Congo, and his high spirits were infectious, for the faces of his fellow annexationists wore the same expression as may be observed at a company meeting after a good half year. His description of the Katanga copper belt was quoted from reports of English engineers and an English Parliamentary document. It is to be hoped that no mistake has been made in the figures. As M. Franck observed later, there are three kinds of inexactitudes: errors, statements contrary to the truth, and statistics—for if Katanga were for any reason to fail to justify the confidence placed in it, those whose shrinking from the cost of the Congo is overcome by the prospects of 'a richer Rand' might find in this event additional proof of England's perfidy."

When I took office the tonnage of copper produced was varying round 20,000 tons a year; the figure for 1919 was even a little lower. Now the copper produced last month alone was 7,500 tons, making an average of between 80,000 and 90,000 tons a year. This places the Congo third in the world production, only the United States and Chili taking precedence. And this is not the end. The reserves are practically unlimited. The cost of production is low; a few years ago, the Katanga factories were able to keep working when nearly all mines were closed.

A new type of smelting furnace has just been tried, which will diminish considerably the working expenses, and when the leaching plants have been completed, the low grade ore will be capable of exploitation. An output of 200,000 tons before we are ten years older will be nothing extraordinary, and this would bring the Congo to the second rank amongst the copper-producing countries of the world.

Copper is not the only mineral wealth of Katanga. Tin exists in great quantities, but it is not yet mined in full, as there are still difficulties of transport. Coal has been found. The Shankishia coal near Bukama is of a good average quality; but up to date none of this coal can be used for the making of coke. Iron ore is found in enormous deposits of high grade up to 65 per cent. of iron and more; but as long as Tropical Africa is not itself a great consumer of steel, or as long as some technical innovations do not occur, these iron deposits are likely to remain a valuable reserve: distance to the coast is at present too great.

On the other hand, precious stones and precious metals are an asset of immediate value. In 1908, the Compagnie Forestière and Minière carried on a very great deal of prospecting outside Katanga and nearly exhausted its capital without any result of importance, when a tube with a small white stone, found near Tshikapa, reached Brussels. It was a diamond. Further researches proved that extensive deposits existed in the southern Kasai district, in the gravel of the river or of its banks. Several beds were discovered; others are still being found in the neighbouring territories. Owing to arrangements which I took when in office, the throat-cutting competition which did so much harm in South Africa at the beginning of the diamond industry there has been avoided. All the concessions are controlled by one organisation, over which the Government is able to exercise the necessary action which public interest may require. So the valuable deposits are worked to their best economical possibilities, and with due care for the native population. The progress has been remarkable. In 1918, the output was 178,000 carats. In 1913 it amounted to 539,576 carats, which is about 20 per cent. of the South African output.

It would have been a pity for us if gold had not kept pace with the diamonds. Well, we have been fortunate also in this direction. Gold placers are successfully mined at Kilo and at Moto, in the North Eastern part of the Colony, near Lake Albert. The output is rising and was last month 388 K°. It is alluvial, but quartz veins of importance and well workable have been discovered. In order to exploit them in industrial conditions, heavy machinery will be necessary. The plan is to await the erection of the factories until the railway reaches this part of the country. In the meantime we exploit the placers, not directly, but through a commercial organisation. So a rush of gold diggers has been avoided, greatly to the benefit of and with regard for the native labourer: food is not available in unlimited quantity, as long as the rail will not bring it to the mines; the district has only a thin population; so any excess in working the deposits would mean great hardships to the black tribes.

The story of radium in the Congo is still more interesting than that of gold and diamonds.

Nobody was thinking that there might be radium ore in the Congo, when, during the war, a mineral of a very special yellow colour attracted attention in Katanga. It was sent to Europe for analysis. The presence of radium was ascertained, and the Congo ore proved so rich that the Americans, who were until then by far the most important producers in the world, have shut their mines and are selling the Congo radium: so the latter is ruling the market. As the Government has an interest in the matter, the price has been seriously lowered in due regard for suffering humanity.

A new discovery is cobalt, also in excellent conditions as to quality, quantity and cost of production. The factory is about to be in working order. Cobalt is at present of limited use, owing to its high price; it is employed for colouring purposes and also as an addition to steel, which it protects against oxidation. But with greater quantities and lower cost it may well obtain new and increased applications. Here also we wish to make progress.

Is the story of the Congo's mineral wealth to end there? Nobody can say. But experts are firmly convinced that when the eastern and north-eastern parts of the colony have been opened by the Stanleyville to Kilo-Moto railway, there will be most remarkable surprises! Oil may exist in the Mayumbe, and certainly the extraordinary underground of Katanga has not revealed all its treasures.

In many cases the great distance from the sea is a drawback to the export of heavy metals, but the low cost of production is a set-off. The native labour day in the Katanga will not cost one half of that on the Rand, while in the more remote districts, Kilo Moto for instance, it is only one fifth or one sixth.

The Black as Artisan. No Colour Bar.—The whole of this industrial development is accompanied by equality of treatment and full opportunity for black labour. The Congo negro is admitted to all work which he proves able to do. Many natives become good artisans, engine drivers and so on. Nothing like the colour bar of the Rand exists in Congo. A few years ago, agitators, coming from South Africa, tried to introduce this distinction in Katanga. They were at once politely but firmly sent back to their own country by order of the Government. They tried to get the Belgian Labour Party to support them. They met with a deaf ear. We consider it against public policy that in his own land the black man should not enjoy the fullest opportunities for all class of work and thereby be able to raise himself to any level he may be able to reach. The Belgian white artisan entirely agrees with these views, and his feelings are fostered by the consideration that most companies pay him a premium for every black apprentice he educates to the trade.

Some of the companies have established industrial schools and are rapidly educating large numbers of black artisans. The Government and the missions have long been on the same path. But the interesting feature of the companies' enterprise is that they try to train several hundreds of artisans, by very practical methods with great care for specialisation. The progress of the industry will therefore prove a bounty to the native. Already he is, in the labour camps, better housed, supplied with better food and blankets and more able to buy clothes than in his native kraal.

There are, however, at present also drawbacks. Tribal morality and tribal sanctions disappear amongst the labourers of the big industrial concerns, but the good effect of a more decent and better life is not always appearing at once. Women are scarce; immorality is rampant and the birth-rate is very low. Efforts are strenuously directed to remedy this bad feature in the reactions of two grades of civilisation, so widely different; after a time, adaptation will allow of the reaping of the full benefits of economical progress.

FINANCE OF THE CONGO.

Is the Congo paying? There has been a school of colonials in Belgium who are of opinion that the Congo ought to pay or at least be self-supporting. I do not belong to that school. A new country with its enormous difficulties wants a great amount of capital to be invested in it. The required degree of investment can scarcely be expected from private enterprise if the Government does not give an example of confidence in the future of the colony by adequately equipping the country and duly administering it and educating the native. Before the war the former view was dominant, and the colonial budgets of that period show it. I was fortunate enough to bring the conviction home to Parliament that those who wish to secure a good harvest must be willing to till and sow with an active and generous hand. It was agreed that during the erection of the great public works, and before they are completed and able to earn the necessary revenue, the metropolis should help the colony. This help has taken the form of an annual grant-in-aid of 15,000,000 fr, which has materially assisted the colony to float the necessary loans. But the market for public loans is not unlimited. Consequently a new financial organisation was planned and prepared by me before I left office.

The very extensive land concessions at the time of the Independent Congo State have practically all been bought in or liquidated in some form by the Government. But mines and mineral deposits are still the object of concessions as in all countries. It is the best means of procuring good management by business men on commercial lines. But the Government of the colony, when granting such concessions, has had foresight enough to reserve for itself a substantial share in the net profits.

It appears to us a sound policy that such valuable natural assets as the copper, diamond, and gold deposits should not be simply given away for the pains of prospecting and working them, but that the community at large should get its due share of profit, so that the wealth extracted from the soil should help to defray the great outlay on sanitary and such work, and on development done for the benefit of the natives and the colonists.

We begin to enjoy the advantages of the system. Two of the companies referred to will pay this year to the colonial exchequer not less than 24 million francs, and the net profit of the gold mines, in which the Government keeps the whole interest, will amount to the same sum. This means together 48 millions.

The valuation of the shares and participation which the colony possesses in that way is so important that on 1st January, 1924, it exceeded the total debt of the colony. The problem now was how to make use of these assets for the execution of our great programme of railways, public works, hygiene and education? It would have been unwise to sell these assets, which keep the control of all these valuable mines under the nation. It was resolved that these shares, debentures and participations should form the capital of a financial or holding company, which will issue loans on account of the Colony and on these assets. The Colonial Government will guarantee a fixed interest. There will be also attached to the new stock, thus issued, a right of participation in the dividends and profits of the colonial shares and debentures; so the man in the street, the peasant on his field, the clerk behind his desk, if they invest their savings in that way will find themselves indirectly shareholders of the copper mines, the diamond-fields, the gold placers, and the radium factory of the Congo. The money thus obtained will be placed by the Government in stocks or shares of the various railway companies which are building the new lines and thereby contribute to the development of the country. In their turn these stocks and shares will be vested in the holding company so that the success of these lines will increase its revenue and supply further credit to facilitate the new emission of loans.

On one hand, you see the Colonial Government considers itself a bad merchant and a poor manufacturer, and leaves the working and management of business to business people; on the other hand, it duly appreciates that the general interest is at stake in several forms of colonial enterprise and gives effect to that consideration by the share it keeps in them or the monetary means it supplies.

I think this to be a quite modern method of public enterprise.

We hope in that way, to supply on favourable terms, our vast development works with the necessary capital and we increase at the same term the general interest of our people in the colony.

This brings me to the end of these very incomplete remarks.

The Congo is at present appealing very much to the mind and heart of our ordinary citizen. The basis of a real colonial career has been laid for the Belgian youth by the creation of the Colonial University at Antwerp. As in all colonising countries the man at home is not sparing in his criticism of colonial administration, but he has learned to feel and love the greatness of colonial enterprise and the lofty aims of human and modern colonisation.

The Congo has enormous potential wealth. It has a great future. It certainly adds a splendid asset to the possessions and credit of Belgium. But it is like the old hostels in Spain, of which it was customary to say that you would find within their walls all you had brought there yourself. Nothing in the Congo would have developed but for the foresight, courage and genius shown by King Leopold, but for the reforms introduced, the pains taken, and the capital invested by Belgium. Nothing will fructify without a continuation of a firm policy of strenuous activity, strong financial support and fair play to all.

We do not believe that in the Congo we are showing new ways to our elders and betters in the colonial field. We are quite content to take a few leaves out of their book and pleased if impartial judges consider that, in a difficult task, we modestly do our best. There is no colonial history without great risks and dark pages. But nobody who reads history, nobody who has gone through the marvellous exhibition now open at Wembley, can be blind to the immense progress and blessings which colonisation, as the British people and the modern mind understand it, have brought to the world and to humanity.

DISCUSSION.

The Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., D.S.O., said he was sure he was voicing the feelings of the audience when he thanked M. Franck for his extraordinarily interesting address. Some years ago there was a belief throughout England that in the times of the Independent Congo Free State the country was very much misgoverned; and that feeling had been shared by a large section of the people of Belgium. It was, therefore, particularly desirable that M. Franck should give an illustration of the great revolution in methods which had taken place in the Congo since it became a Belgian colony. This revolution in the methods of government in the Congo was of extraordinary interest to all Powers exercising control in Tropical Africa. In this transformation M. Franck, not only from his long tenure of office as Secretary of State for the Colonies, but also from his personal visits to the Congo, could justly claim to have had a very large share.

M. Franck had stated that in his view the whole problem of the Congo might be summed up in the two words—"population" and "transport." He had told them a great deal about the way in which the arterial system of railways had been and is being developed in the Congo—and a most excellent system it seemed to be. The next point was: What were to be the feeders of those railways? On that point M. Franck had not said very much. Personally he (the speaker) thought the narrow gauge feeder line was a mistake; it meant duplication of workshops, rolling-stock, etc., and if bridges were made broad enough and strong enough to carry a heavier line later on, its cost was practically as much as that of the standard gauge. Nor did he himself think that roads offered a final solution. He agreed that motor transport was too costly for Africa, and motor roads cost there nearly as much as the light line itself. Not only was their initial cost great, but their upkeep in a tropical country, subject to tropical rainfall, was practically prohibitive. Consequently the solution, in his opinion, was to find some method of cross-country transport such, for instance, as the Citroen car, or some form of wheelless vehicle, which could go across country and do without expensive roads. The British Empire Cotton Growing Corporation had undertaken to investigate that question, and had appointed a committee, who had already, he believed, presented a report. He hoped they would now go into the kindred problem, the question of a cheap liquid fuel. Those two problems—a cross-country method of transport and a cheap liquid fuel—were the ones which most concerned those interested in the development of transportation in Africa.

With regard to population, M. Franck had described the various efforts which had been made to improve the condition of the natives, and he would only add one word on that point. As a Member of the Mandates Commission, he had been struck this year, when examining the Urundi Reports, to learn that the itinerant trader was completely prohibited in Urundi. The reason given was that he was a carrier of disease. He (Sir F. Lugard) thought this country had something to learn in that respect. In West Africa, in particular, the people were very keen traders. The itinerant trader went everywhere now under British rule, and in his opinion such a man should be subject to licence and medical inspection. Another lesson which we might learn in connexion with our British possessions was the system of training native assistants to be fairly skilled in the treatment of five or six special diseases. With intelligent natives we could really get some measure of skill and knowledge in regard to four or five particular diseases without attempting to make them general practitioners.

Generally speaking, he thought the policy which M. Franck had outlined—the idea of the country being ruled through, and by the aid of, the native Chiefs, the conception of individual freedom to the native, and so on—was one which would find warm approval in this country.

In conclusion, he desired to say one word with regard to what M. Franck had said in respect to concessions. The chief criticism of the old régime in the Congo was the enormous concessions given to individuals. The task which the Belgian Government had had in buying out or liquidating those concessions must have been a very difficult one, and we congratulated them heartily on the fact that they had succeeded in doing it. The present-day concession was a very different affair. Instead of the concessionaire exploiting the native without any corresponding advantage to him, the former was now called upon to establish schools, to provide medical officers, to establish dispensaries, and finally, to share the profits of the enterprise with the Government. He (Sir F. Lugard) thought the system was an admirable one, and he hoped that there would be much profit to share after all those conditions had been carried out.

Mr. H. R. Greenhalgh said Lord Leverhulme, who had had to leave the meeting in order to keep a very important engagement, had asked him to express his grateful thanks for M. Franck's references to his Company, and to say that, in all the developments which they had undertaken in the Belgian Congo, they had at all times received the greatest possible consideration and help from the Administration under M. Franck. Personally he would like to take the opportunity of saying that he himself had had the pleasure of touring through the Congo twice, and that he had been greatly interested in, and could bear witness to, the very excellent administration which at present prevailed in the Congo.

Mr. E. Torday agreed with Sir Frederick Lugard's statement that the itinerant trader was an extremely great danger as a carrier of disease. As a proof of that, in those parts where such men did not exist in the Congo, sleeping sickness was absolutely unknown.

Concerning the introduction of European civilisation into Africa without destroying that which already existed, one was accustomed in speeches by politicians to hear a lot of pious wishes expressed, but M. Franck had done very serious and considerable work in furtherance of that idea. It was a very ungrateful task, because one had to appeal to the electorate in terms of money, and one could not show any quick return. He believed the establishment of a Colonial University, and of the system of sending young Belgian students to study native languages, would bear very good fruit in the future, though at present it might be considered unproductive. One could not in a few years educate the native up to a civilisation which had taken Europe two-thousand years to acquire, and it would be a great mistake to destroy that which already existed in Africa, much of which was very admirable.

The Chairman (The Hon. W. G. A. Ormsby-Gore) said he would like to say, as late Under-Secretary for the Colonies in this country, with what extreme interest he had listened to M. Franck's lecture. When one investigated the problems, they were, he believed, all coming more or less to the same conclusions. The first thing which had come into his mind when M. Franck had, quite rightly, justified what was being done by European Powers in Africa, had been the memory of the English philosopher Hobbes, who first opposed the prevailing Continental conception of the "noble savage." Rousseau had said that if Europe could only get rid of its kings, priests and lawyers, and return absolutely to nature, everyone would be happy ever afterwards. It was easy to think that in Geneva. It was not easy to think it in Africa; and the English philosopher was really right. The life of primitive man in his natural conditions in Africa was, in the words of Hobbes, "poor, dangerous, nasty, brutish and short." Tropical disease, local wars and many barbarous customs had to be stamped out before all that was best in the native outlook and in the native capacity could be developed. Before the moral and intellectual, and even political, development of the native of Africa could take place, the economic development of the country was absolutely essential, both to provide the native himself with freedom and wealth to advance, and to provide the State and the country with the means to help him. It was perfectly clear that, mistakes having been made in the past, we were approaching an era where there was common ground between the official, the missionary, the merchant, etc.; that we were entering an era in which all realised that we had, if only on the grounds of self-interest, a common interest in the intelligent development and the true welfare, material and moral, of the native. What M. Franck had said about the experiments in the Congo in regard to the selection of a certain number of natives as medical assistants found a counterpart in only one British territory, Uganda, where, owing to the scourge of syphilis, we had, with the very greatest success, trained a few natives as medical missionaries, as well as practitioners, to deal with that specific disease.

Everything seemed to point to following the advice which M. Franck had given, namely, that in Africa we should not always seek perfection, but should be content to advance one step at a time, and to make the utmost use of all the means to advance, especially those indigenous in the country. What M. Franck had said about the religious character of Africa was being more and more recognised in education and other things. The real difficulty was that, in spite of the fact that so many African natives seemed to be cheerful persons, in the past the lives of the people from birth to death had been surrounded with fear. It had always struck him as extraordinary the degree to which fear had entered into the lives of the Africans—not merely fear of their neighbours and of the physical disasters which might suddenly come upon them, but the haunting trees, the haunting animals—the general hauntedness of Africa. That consciousness of surrounding evil spirits was one of the things which was most difficult to eradicate or to replace by adequate restraint and an influence which would enable the natives to build up a new morality not based on fear.

M. Franck had referred to the question of education. He himself, with Sir Frederick Lugard, had been engaged that morning on the Advisory Committee which had been established in this country in connexion with African education. The Committee was started last year when he was at the Colonial Office, and he thought it had only been started just in time. The secretary of the committee had just arrived back from East Africa, and Sir Frederick Lugard asked him: "Have you brought back any text-books which are being used in the schools?" The answer was "Oh, yes; I have brought back 200." He (the speaker) had shuddered to think of those unfortunate Africans—200 English text-books. Everyone knew what the English text-books in our own elementary schools were like; and the disastrous results they were very often producing in this country. What still more disastrous results might be produced in Africa! We were, on the lines which M. Franck had laid down quite rightly, at the very beginning of the subject of the education of the native for life in Africa, with all that that meant. That was the great point.

It had been very kind of M. Franck to mention that the rectification of the frontier of Urundi, in which he (Mr. Ormsby-Gore) had a small part last year, had proved of satisfaction to that remarkable people. If it had not been for the existence of the Mandate system, and of the League of Nations, there would have been no means of getting any rectification when the facts had been ascertained.

The future of the Belgian Congo would be watched with the greatest and most sympathetic admiration by all British students of Colonial administration. It was a great stimulus to those who were engaged upon the problem in Great Britain to hear how another Colonial Power, which was playing an honourable and distinguished part in the civilisation and development of Africa, was tackling, and tackling so nobly and so successfully, the problem which faced it.

Major Sir Humphrey Leggett, D.S.O., R.E., said that as a member of the Council of the Royal Society of Arts, it gave him great pleasure to move a vote of thanks to M. Franck for his lecture, and also to Mr. Ormsby-Gore for presiding. Mr. Ormsby-Gore had made such subjects as M. Franck had dealt with peculiarly his own. In the field of politics there was room for opinions many and diverse, for "crankiness," for preconceived ideas, for empirical views; for lack of foresight and inability to keep abreast of the times or, what was best of all, to go ahead of the times. Mr. Ormsby-Gore had referred to the haunting fear of the African native—how he was haunted by strange fears of the unknown; but he (the speaker) ventured to think that the Government of this country had sometimes in the past been haunted by another kind of fear in connexion with Africa, namely, a financial fear, and that it had not put into Africa that financial backing without which, as the Chairman had pointed out, nothing could be done. After the building of the Uganda Railway, an undertaking mixed with many political issues, there came a long period when it had been very difficult indeed to extract money from the Treasury with which to lay a foundation for the future of Africa. M. Franck had shown how Belgium, with great vision and great courage, and something more than courage, with knowledge and clear insight into the potentialities which were there for development, had not hesitated to lay down plans which would carry her, not for a year or two ahead, but for long periods ahead, so that the future of her great Possession was indeed assured. The plans of which M. Franck had spoken that afternoon involved an expenditure which the Belgian Government, under M. Franck's guidance, had earmarked, or implied its intention to provide, of no less a sum than twenty millions sterling. With the assurance of that sum one could see how the development of that great territory could be taken in hand by statesmen and administrators with a certainty that they were going to produce results—and great results. They could lay down plans, and they could be sure that their plans would not fail through the stoppage of financial supplies. They clearly did not share the haunting fear which the native of Africa had in his little way. The Government of Belgium in its African policy had no fear; and he trusted that Mr. Ormsby-Gore, who had done so much to impress upon the British Treasury the future greatness of Africa, would, as a result of his very important mission to East Africa, come back more convinced of the great possibilities of those territories, and would impress still more forcibly upon the Cabinet of the day, and the Treasury, the potentialities of Africa.

The Royal Society of Arts was formed more than 150 years ago for the development of arts, manufactures and commerce. In those days nobody had thought of the centre of Africa. It was only during comparatively recent times that the Society had been thrown open to such subjects as M. Franck had dealt with that afternoon. It was only in the period referred to that the Council of the Society began to invite distinguished administrators and statesmen of our Allies to address the Society so that we could learn from them what they were doing and could see how we might co-ordinate. That brought him to the point that he desired to suggest to the Chairman and to M. Franck, namely, that, just as in learned Societies, such as the Royal Society of Arts, people came together and talked very frankly, so, more and more, co-ordination and consultation should be arranged between the administrators, not only of the different British territories, but of those of our Belgian and French friends. The more we all pulled together the more we should learn, and the more successful would our efforts be.

Sir Sidney Henn, M.P., in seconding the motion, said the address of M. Franck very largely coincided with the thoughts that had been coming to his mind over the last few months when he had been interesting himself rather closely in matters connected with the African Colonies. He quite agreed that the two great questions were transportation and population. He thought that was the right order in which to put them, because, although in many respects the question of native population was really the most important, nothing could really be done of an effective character without first of all providing the necessary transportation; and in that connexion he had been pleased to hear the reference made by Sir Fredrick Lugard to the fact that in the word "transportation" not only the question of railroads was considered, but the even more difficult question of cross-country traffic. He fully agreed with what Sir Frederick Lugard had said upon the matter.

M. Franck, in acknowledging the resolution, said he thought the unanimity of opinion which hade been expressed about the real aims of colonisation to-day would lead to results which would be a victory for humanity and justice.

GENERAL NOTE.

Thirteenth Century Glass-painting.—With the generous assistance of Sir Otto Beit and the National Art-Collections Fund, the Victoria and Albert Museum has recently acquired a fine panel of 13th century stained glass. The panel, about twenty inches square, is in a remarkably good condition, very little decayed and practically free from restoration. It shows a saint disputing before an audience, and is a typical example of the bold conventionalised style of the thirteenth century. Its place of origin is unknown, and it belongs to a period of stained glass design in which it is very difficult to make a distinction between the schools in France and in England, but the history of this particular panel makes it probable that it is English, and in any case it is an example of the art of stained glass at the height of its achievement. It is exhibited among the 13th century stained glass in Room 110.

COBB LECTURES.

CERTAIN FUNDAMENTAL PROBLEMS IN PHOTOGRAPHY

By T. Slater Price, O.B.E., D.Sc., F.I.C., F.R.S.

(Director of Research to the British Photographic Research Association).

Lecture I.—*Delivered March 24th*, 1924.

The modern photographic dry plate or coated film consists essentially of a suspension of fine particles of silver bromide in gelatin, this being spoken of as a photographic or sensitive emulsion. Although gelatin had previously been used as a medium in various experiments with silver salts, it was an English amateur photographer, Dr. Maddox, of Liverpool, who, in 1871, first used a gelatin-silver bromide emulsion to make a dry plate. Very little notice of this was taken, however, until 1873, when Burgess placed on the market an emulsion made by a secret process, and Kennett patented a quick and easy method, which was quite successful, of preparing gelatin emulsion plates by using a "sensitive pellicle," that is, a pellicle of dried sensitive emulsion. Since that time progress in the manufacture of dry plates, coated with gelatin emulsions. varying enormously in sensitivity and in the uses to which they may be put, has been very rapid, and the excellence of the products produced to-day is attested by the fact that, with suitable precautions, they may be used the wide world over, notwithstanding the large variations in climatic conditions.

Without intimate knowledge of the subject one might think that the high standard of present-day manufactures is due to exact and detailed investigations having been made of the chemical and physical properties of gelatin and of the effect of variations in these properties on those of the sensitive emulsion produced. Such an assumption would not, however, be altogether correct—indeed, one might say that it would be far from correct. Although the manufacturer, as a result of the experience gained over a long period of years, can produce photosensitive emulsions having very varying properties, yet, as far as I am aware, it is not known with anything approximating to certainty what is the cause of photosensitivity and why the various processes used produce the required results. It is a matter of common knowledge that if the same gelatin is sent to two different firms, the one may reject it as unsuitable, whilst the other is just as likely to say that it is eminently satisfactory. Apart from certain simple preliminary tests, the final and conclusive test of the emulsion maker is always the practical one of making an experimental emulsion and seeing if it has the desired properties.

The question to which an answer has to be supplied is: What particular properties does gelatin possess which make it particularly suitable as an emulsion medium? A complete answer to this question would have to deal with both the chemical and physical properties of gelatin, but at the present time it is very incomplete, owing to the limited extent of our knowledge. As far as the chemistry of gelatin is concerned, it may be said to be in its infancy, both with respect to our knowledge of what happens when it is prepared from bones and hides, and also as regards its constitution. Belonging as it does, to those complex substances, the proteins, its chemical investigation is a very difficult problem, and essentially progress has only been made in the examination of its degradation products, which consist mainly of amino—acids. It is very doubtful whether gelatin has yet been obtained as a definite unitary product, although considerable progress has been made in this direction by Schryver, and the purest photographic gelatins probably contain varying amounts of degradation products or other organic impurities, in addition to inorganic matter, which constitutes the ash. At present, there is no satisfactory method of estimating the amount of these degradation products, so that a suitable method for differentiating chemically between photographic gelatins, which are ordinarily of a very high state of purity has yet to be devised. There are, however, certain impurities which should not be present in more than negligible quantities, and which can be detected by the ordinary methods of analysis, as, for example, copper, lead and iron. Organic sulphur, reducing substances, and greasy matter should also be absent.

In view of the complex chemical nature of gelatin it is not to be wondered at that the enormous literature on the subject consists, to a very large extent of accounts of the results obtained in the investigation of its colloidal properties, a knowledge of which, as will be seen later, is very important when dealing with the photographic plate. Actually the word "colloid" is derived from the Greek word κόλλα, meaning glue, and at the time when this term was first used by Graham it was supposed that all colloids were substances of very complex constitution, just as is glue. This, however, is by no means true, so that the meaning of the term colloid is now quite different from what it was in Graham's time. It is true that complexity of chemical constitution is likely to give rise to the colloidal state, but the converse does not necessarily hold; the elements themselves may often be obtained in so-called colloidal solution.

It may perhaps be advisable to indicate briefly what is meant by a colloidal solution. If a solution of white arsenic (arsenious acid) in water is mixed with an equal volume of an aqueous solution of hydrogen sulphide no formation of a precipitate occurs; a transparent, somewhat orange-coloured solution is obtained. Apparently it is quite a good solution, and remains as such when any excess of hydrogen sulphide has been removed by bubbling hydrogen through it. It can be filtered in the ordinary way, without leaving a residue on the filter paper and it does not settle out on keeping for quite a long time. That it is not a true solution, however, is proved by the fact that it shows the Tyndall phenomenon; if a strong beam of light is passed through the solution its path is shown up exceedingly clearly, just as the ray of light is made evident by the dust particles in the air. If water, or a solution of ordinary salt, is tested in the same way, the path of the beam of light through the solution is not visible so long as there are no suspended particles in the water or solution. The orange-coloured liquid is therefore not a true solution; it is a suspension of arsenious sulphide in such fine particles that they are not visible to the naked eye and do not readily settle out. For such a system the term "colloidal solution" is often used; it consists, however, of solid particles suspended or dispersed in a dispersion medium and a more appropriate term would be "suspensoid sol", the arsenic sulphide being a "suspensoid colloid". In most suspensoid sols the existence of the particles cannot be demonstrated by the highest power microscope, but by use of the ultra-microscope their presence can be made evident. The particles are then seen to be in rapid Brownian movement.

Compared with gelatin, arsenious sulphide is a very simple substance, but, as has already been mentioned, the simplest substances of all, namely, the elements, readily give suspensoid sols. One knows how very readily a solution of gold chloride is reduced, giving a blackish or greenish-black precipitate of gold; if, however, the reduction is carried out in very dilute solution, suspensoid sols can be obtained. To about 100 cc. of distilled water are added a few drops of a neutralised one per cent. solution of gold chloride, and then, after mixing, a few drops of a 0.1 per cent. solution of tannin. The solution is colourless, but on heating it begins gradually to take on colour and finally becomes cherry red; a red suspensoid sol of gold is then obtained. If instead of using tannin as the reducing agent, hydroxylamine is used, a violet, or blue colloidal solution is obtained, the particles of gold being larger that those in the red sol. It has been shown by the method of X-ray analysis that the particles have the same crystalline structure as massive gold.

A characteristic property of suspensoid sols is that they are readily coagulated or precipitated when solutions of electrolytes are added to them, the electrolytes used not necessarily having any chemical action on the particles of the sol. For example, solutions of hydrochloric acid, sodium chloride, magnesium sulphate, or aluminium sulphate, cause an immediate precipitate of yellow arsenious sulphide when added to the sol of that substance.

So far the colloidal solutions mentioned have consisted of solid particles suspended in a dispersion medium. Consider now, however, an emulsion such as cod-liver oil emulsion, or milk. If it is examined under a microscope it will be seen to consist of drops of one liquid suspended in another liquid. If it were possible to reduce the drops to colloidal dimensions a colloidal solution consisting of liquid particles in a liquid dispersion medium would be obtained. Such a system may be called an "emulsoid sol", and according to some chemists, especially Wo. Ostwald, gelatin gives such sols with water; other chemists, and they are in the majority, do not agree with such a structure in the case of gelatin. The question of structure, as far as we are concerned at present, is, however, a subsidiary one, since an emulsoid sol can, in general, be readily distinguished from a suspensoid sol. Suspensoid sols are practically as mobile as water itself, that is, the dispersed particles hardly alter the viscosity of the dispersion medium. On the other hand, emulsoid sols, of which gelatin is a typical example, show large viscosity values, even in comparatively low concentrations, and with increase in concentration the viscosity increases enormously, whereas there is only a small increase in the viscosity with suspensoid sols under similar conditions. Also, when a gelatin sol is cooled down it is well known that it sets to a jelly, that is, it becomes a gel, whereas no such change takes place with a suspensoid sol, such as that of gold, when treated in the same way. Moreover, the change from sol to gel is reversible, since on warming the gel it readily liquefies to a sol. Again, if the gel is dried and then immersed in water it imbibes water and swells to a greater or lesser extent.

In the case of a suspensoid it was shown that the addition of a small quantity of a salt to the sol caused precipitation or sedimentation to take place. With gelatin this only happens when large concentrations of salt are added, and not always then. It is fortunate that this is the case, otherwise gelatin could not be used as a medium in the preparation of photographic emulsions. Although precipitation does not occur the salts have a very marked effect on the viscosity, sometimes increasing, and sometimes decreasing it. For example, a 1½ per cent. sol [*] of gelatin, set to a gel in test tube, can be detached from the sides of the tube and broken in pieces by hard shaking. If, however, several per cent. of magnesium sulphate are added to the sol before setting, the resulting gel can be no longer broken up by shaking. On the other hand, if sufficient potassium iodide is added to the sol it will not set and remains fluid. Sulphates, citrates and phosphates act similarly to magnesium sulphate, that is, they increase the jelly strength of the gelatin, and to a much greater degree than they do that of pure water. Bromides and cyanides act similarly to iodides. Organic substances also act differently, for example, chloral hydrate and urea decrease the viscosity, whilst alcohol, in small amounts, increases it.

Similar results would be obtained if, instead of using a gel, the viscosity of the sol were measured in a viscometer. Such measurements would show, however, that further complications arise, in that there may be either an increase or a decrease in the viscosity, depending on the concentration of the added salt. For example, sodium chloride in medium concentration (about N/4) produces a viscosity which exceeds that of pure gelatin, whereas at higher or lower concentrations the viscosity is less than that of pure gelatin.

This, however, is much better shown in the case of the influence of the acids and alkalis, as is illustrated by the following figures and curves, which are due to von Schroeder. (Fig. 1.)

Conc. of HCl or NaOH	O	N/512	N/256	N/128	N/64	N/32	N/16	N/8	N/4
Rel. Viscosity (HCl)	1.40	1.55	1.76	1.68	1.58	1.42	1.25	1.17	1.12
Re . Viscosity (NaOH)	1.40	1.52	1.60	1.79	1.62	1.38	1.25	1.10	1.10

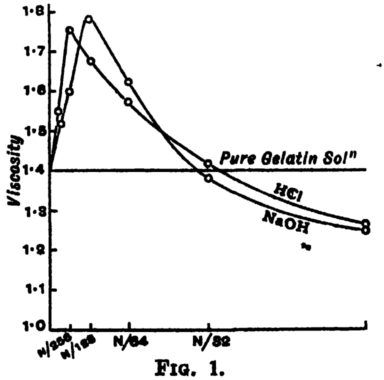

FIG. 1.

---

[*] The concentration necessary to give these results will depend on the kind of gelatin used.

It will be noticed that there is a pronounced maximum viscosity.

Similar complicated phenomena occur in connexion with the swelling of gelatin. It is well known that if a piece of leaf gelatin is put into water it takes up water and increases in volume, that is, it swells. Swelling will take place not only in water as a liquid, but also in water vapour. If a piece of thin leaf gelatin is put on a piece of filter paper and then breathed upon, it immediately bends or even curls up, showing that there is an increase in volume of the gelatin on the side which is breathed upon, that is, swelling has taken place.

The effect of various substances on the swelling may be demonstrated as follows :—A series of gelatin discs of the same size and weight are prepared by pouring a concentrated gelatin sol on a glass plate, allowing it to set, and then cutting the set gelatin into discs and drying. If separate discs are then immersed for twenty-four hours in solutions of N/20-HCl, N/20-NaOH, N/2-KI, N/5-$CaCl_2$, water, and saturated magnesium sulphate respectively, it will be noticed that the order in which swelling has been favoured is :—acid > alkali > potassium iodide > calcium chloride > water > magnesium sulphate ; the disc in the acid solution will be swollen to about twice the size of that in pure water.

The results of investigations such as those indicated led to the putting forward of what are known as the Hofmeister series, Hofmeister being the one who first studied such effects. For example the effect of equivalent (tenth normal) solutions of various acids on the swelling is indicated by the following series :—hydrochloric acid > nitric acid > acetic acid > sulphuric acid > boric acid.

With sodium salts of various acids the swelling decreases in the order :—thiocyanates > iodides > bromides > nitrates > chlorates > chlorides > acetates > tartrates > citrates > sulphates.

Such series are very difficult to understand, since the order of the compounds does not bear much relation to their ordinary properties ; it is difficult, for example, to comprehend why acetic acid comes between nitric and sulphuric acids.

It is the realisation that gelatin does not behave simply as a colloid, but has both acid and basic properties, which has brought some order out of chaos in recent years. For progress in this direction we are chiefly indebted to the work of Procter in England, Pauli in Austria, and Loeb in America.

As has been mentioned, the exact chemical constitution of gelatin is still a mystery ; it is known, however, that amino-groups ($-NH_2$) are present in the molecule, and in all probability imino-groups ($-NH-$) as well, which confer basic properties on it, and that the molecule also contains carboxyl groups ($-COOH$) which confer upon it an acid character. It is, in fact, an amphoteric substance similar in character to glycine, or aminoacetic acid, $NH_2.CH_2.COOH$, and for ordinary purposes its formula may be represented as $G\left\langle\begin{matrix} NH_2. \\ COOH. \end{matrix}\right.$ where G represents the gelatin residue. If a substance behaves both as an acid and a base it is weak in both these properties, but it does not follow that its strengths as acid and base are the same. Actually these strengths are generally different and both glycine and gelatin are stronger acids than bases. Suppose now that hydrochloric acid is added to a gelatin sol ; it will combine with the amino-group of the gelatin and form the salt, gelatin hydrochloride. If the solution so obtained is electrolysed the gelatin part of the molecule, since it possesses a positive charge will travel towards the negative electrode, the cathode. If, on the other hand, sodium hydroxide is added to the solution the acid group of the gelatin enters into reaction and a sodium gelatinate is formed ; the gelatin part of the molecule is now negatively charged and on electrolysis will travel towards the positive electrode, the anode. It follows that the direction of migration of the gelatin as a whole depends on the acidity, counting alkalinity as negative acidity, of the solution. There will therefore be some point at which the acidity of the solution is such that on electrolysis the gelatin does not migrate preferentially to either electrode ; this point is called the isoelectric point, and the gelatin is said to be in the isoelectric condition. Gelatin being a stronger acid than a base, this will not be at the neutral point, where the concentration of hydrions ($H^{\cdot}$), to which acidity is due is equal to the concentration of hydroxyl ions, (OH'), which ions confer alkalinity on a solution, but at some point on the acid side of the neutral point. By experiment it has been found that in an isoelectric solution of gelatin the concentration, $C_{H^{\cdot}}$ of the hydrions is $2{\cdot}5 \times 10^{-5}$

gram-ions per litre. Another way of stating this is commonly used in the literature; the logarithm of $2{\cdot}5 \times 10^{-5}$ is $\bar{5}.39794$, or -4.60206, that is -4.6; the isoelectric point is then said to be at a value of P_H or pH $=4.6$. It is now commonly accepted that the isoelectric point of gelatin has a value pH$=4.6$—4.7*

The exact theory of amphoteric electrolytes shows that at the isoelectric point their solutions will contain a maximum number of neutral molecules and they should therefore possess peculiar properties; in accordance with this it has been found that the properties of swelling, viscosity, osmotic pressure, etc., show a minimum at that point, whilst the precipitation by alcohol is most pronounced. If to a one per cent. solution of isoelectric gelatin alcohol is added, there is an immediate precipitation; but if the solution is first acidified slightly with hydrochloric acid there is no precipitation on the addition of alcohol. Also if a one per cent. solution of isoelectric gelatin is made in the warm it is clear and transparent; on keeping at the ordinary temperature, however, the solution becomes opaque after a time and a precipitate may deposit on keeping; raising the temperature again gives a clear solution. The setting of the solution to a gel is a different process from this precipitation, since cloudiness or opacity is not connected therewith.

On the acid side of the isoelectric point (pH $<$ 4.7) gelatin should therefore behave as a base and form gelatin acid salts, whilst on the alkaline side (pH $>$ 4.7) it should act as an acid and form metal gelatinates. Loeb has endeavoured to show that this is true in several ways, of which the following, since it makes use of silver salts, may be quoted. Separate quantities of gelatin, in the form of granules, are brought to different pH's less than 7.0 by treatment with varying concentrations of nitric acid. The separate portions are then soaked for an hour in a dilute solution of silver nitrate, after which they are washed several times with ice cold water. They are then melted, diluted to the same volume in each case and portions of each put in test tubes and exposed to light, the previous manipulations having been carried out in a dark room. The pH's of the solutions remaining are determined and also the quantities of silver remaining in them. In a short time all the gelatin sols with a pH $>$ 4.7 become opaque, and then black on exposure to light, while all the solutions of pH $<$ 4.7 remain transparent, even when exposed to the light for months. The sols of pH$=$ 4.7 become opaque, but remain white since the gelatin is isoelectric. It follows that the silver combines with the gelatin only when the pH is $>$ 4.7, that is, metal gelatinates are formed on the alkaline side of the isoelectric point. The accompanying figure (Fig.2.) is a photograph, due to Loeb, of a set of test tubes thus prepared. It should be noticed that in all cases the pH of the various solutions is on the acid side of the neutral point, pH$=$7

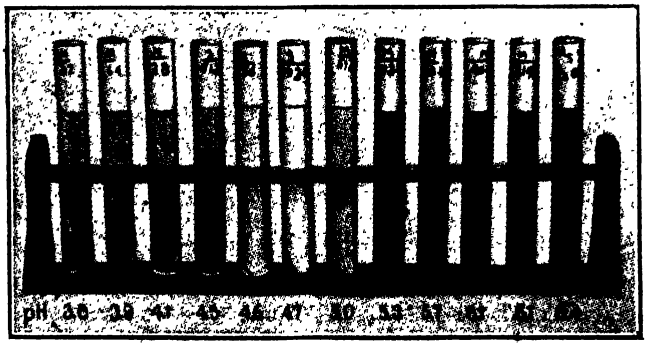

FIG. 2.

The analytical figures are given in the following table and illustrated in the lower part of Fig. 3.

The upper curve in Fig. 3. shows how the swelling of the gelatin varies with the pH, and illustrates the point to which reference has already been made, namely, c.c. 0.01N-Ag in combination with 0.25 gm gelatin at different pH's.

---

* The neutral point of water is approximately at pH$=$7, the exact value varying with the temperature, so that the isoelectric point of gelatin is on the acid side of the neutral point. It should be noted that with this method of nomenclature the greater the concentration of hydrions the less is the value of the pH.

pH	3.6	3.7	3.9	4.1	4.3	4.6	4.7	5.0	5.3	5.7	6.1	6.4
c.c.	0.5	0.3	0.3	0.2	0.2	0.2	0.55	1.25	3.2	4.0	4.85	4.9

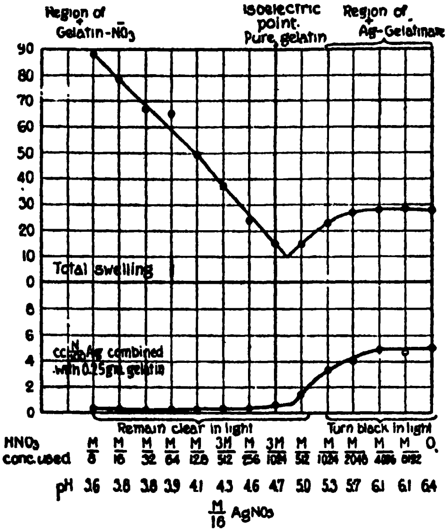

FIG. 3.

that the swelling is a minimum at the isoelectric point.

Results similar to those with silver nitrate are obtained when a nickel or a copper salt is used. With potassium ferrocyanide the gelatin retains the ferrocyanide, as gelatin ferrocyanide, on the acid side of the isoelectric point, the gelatin turning blue after a few days, owing to the formation of ferric salt. Another important result which follows from these considerations is that a basic dye is retained by gelatin on the alkaline side of the isoelectric point and is not removed by washing, whereas on the acid side the same dye is readily removed by washing. On the other hand, acid dyes are retained by gelatin when the pH is less than 4.7.

Another deduction which can be made in connexion with the pH of gelatin solutions is that if the effects on swelling, viscosity, etc., of various monobasic acids (HCl, HBr, HNO_3, $CCl_3.COOH$. etc.) and acids such as succinic, tartaric, citric and phosphoric acids, which dissociate only into two ions at ordinary dilutions, are compared at the same pH, they should be the same; dibasic acids which dissociate into three ions at ordinary dilutions, such as sulphuric acid, should give different effects. The accompanying figure (Fig. 4.) shows that within the error of experiment this is the case for swelling, and it has been shown to hold for other physical properties.

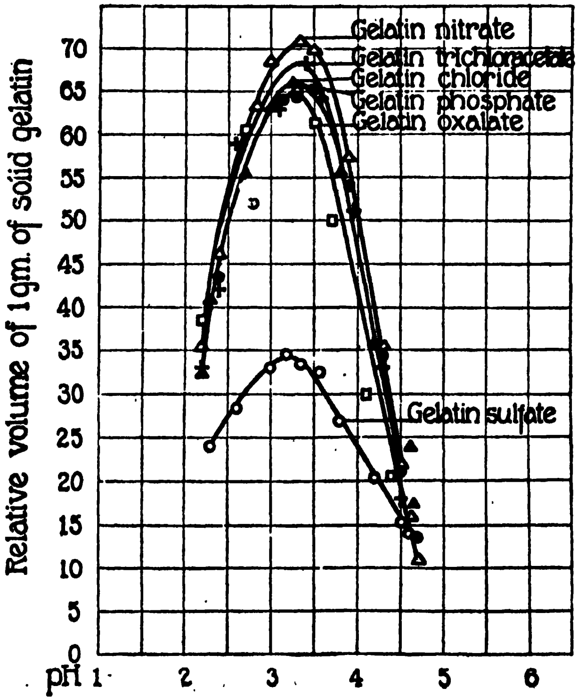

FIG. 4.

If the curves are compared with those which would be expected on the basis of the Hofmeister series, those for phosphates, oxalates, citrates, and tartrates should be in the region of the sulphate curve.

Similar results are obtained with the alkalis ; the curve for the weak base ammonium hydroxide is the same as that for the strong bases, lithium, sodium and potassium hydroxides, when plotted with pH as abscissae, whilst the curves for calcium and barium hydroxides are considerably lower.

It is obvious from the above that in processes where gelatin plays a part it is important to know the pH value. Some investigators have gone so far as to maintain that the properties of gelatin and similar substances can be completely explained by their amphoteric character and the ordinary stoichiometric chemical laws. Actually, however, there seems to be no doubt that both the amphoteric and colloidal properties must be taken into account, as will be seen now that we can proceed to consider more especially the use of gelatin in photographic processes. In the course of these considerations it will be necessary to interpolate, at times, accounts of other properties of gelatin to which, so far, reference has not been made.

It is perhaps advisable to indicate briefly how a photographic emulsion is made. An aqueous solution of potassium or ammonium bromide, to which also a small percentage of the iodide may have been added, and containing a little gelatin is warmed to a definite temperature until all the gelatin has dissolved. A solution of silver nitrate is then run in, the amount of silver nitrate being insufficient completely to precipitate the bromide ; also, the silver nitrate may, or may not, be completely converted into silver ammonia nitrate. The emulsion so obtained is heated for some time, during which it becomes more coarsely grained in character, after which sufficient gelatin is added to cause the whole to set to a stiff gel on cooling. After setting in this way the gel is shredded in a special apparatus and the shreds thoroughly washed with water until the soluble salts and ammonia have been removed. The washed shreds are then melted up again and heated at a definite temperature for some time, during which the process known as ripening takes place, that is, the grains increase in sensitivity towards the action of light. When the desired sensitivity is attained, the emulsion may be coated on plates or films, which are then dried; etc. These details are capable of almost infinite variation, according to the result which it is desired to obtain.

All gelatins, even the purest photographic gelatins, contain a certain amount of ash, due to inorganic impurities present, and one would imagine that the first thing to do would be to purify them from these extraneous constituents. Bearing in mind what has been said about isoelectric gelatin a method of purification can be readily devised, although the details of manipulation may be complicated. Ash-free gelatin has been obtained and C. R. Smith in America and Professor Luther in Germany have stated that with such a material it is impossible to get a sensitive emulsion. Smith draws the conclusion that the sensitivity of an emulsion is therefore controlled by the ash constituents, but it is early days to make such a definite statement. The processes used to remove the ash may quite possibly affect the gelatin and alter its physical properties very considerably In his experiments Luther used gelatin purified by electro-osmotic methods by the Deutsche Electro-Osmose-Gesellschaft and in a recent paper by Izaguirre in the *Kolloid Zeitschrift* it is shown that such gelatin behaves physically in a very different way from ordinary photographic gelatin. It is reasonably certain, however, that the physical properties of a gelatin do not alone confer on it its photographic properties. Emulsions have been made according to the same formula and procedure, and using gelatins of different origin but having practically the same physical properties. Microscopic examination showed that they were substantially alike as far as appearance was concerned, but actually their photographic properties were very different.

The part which gelatin plays at the actual moment of precipitation of the silver halide is probably very important, but hitherto there has been very little published on the matter. Before this can be dealt with, however, it is necessary first to refer to the influence of the concentration of reactants on the dispersity of the insoluble product formed. This can be illustrated by the following experiments :— If two very dilute solutions of ferric chloride and potassium ferrocyanide are mixed a sol of Prussian blue is obtained ; it is perfectly clear to the naked eye. If, however, more concentrated solutions of the same compounds are used, the ordinary precipitate of Prussian blue is obtained, that is, the degree of dispersion is less, the size of particles being greater. Finally, if saturated solutions of the two salts are mixed in the proportion of two volumes of the ferrocyanide to one volume of the ferric chloride solution, the latter being poured into the former, a stiff paste is produced and the containing vessel can be inverted without losing its contents. If a little of this paste is mixed with a large volume of water it gives a clear, blue sol, similar to that obtained with dilute solutions of the reactants. It follows that when highly concentrated solutions are used the size of the insoluble particles is again decreased, that is, the dispersion is increased. That this is a fairly general phenomenon has been shown by von Weimarn, * and the following table, due to Sheppard and Trivelli, shows that it is true when equivalent aqueous solutions of silver nitrate and potassium bromide are mixed, with the formation of silver bromide.

Normality	Dispersity.	Remarks.
0.0002	Clear sol	Increasing Dispersity ↑
0.0004	Clear sol	
0.0010	Opalescent sol	
0.0025	Cloudy suspension	
0.025	Unstable suspension	
0.25	Flocculent → crumbly precipitate	
0.75	Flocculent → milky above silt → curd	
1.50	Flocculent precipitate → sandy precipitate	
3.00	Curdy → crumbly precipitate	Increasing Dispersity ↓
4.50	Curdy → voluminous gel	

When the precipitation is carried out in the presence of gelatin the latter has a very marked effect; the silver bromide is obtained as a sol at concentrations of the reactants which, in pure aqueous solutions, would give a coarse-grained precipitate. This can be shown as follows:—To 20cc. of water are added two drops of 0.1-NAgNO_3 and the solution then divided into two halves, A and B. To A is added 1cc. of a 0.5% gelatin sol and to B 1cc. of water, after which 3 drops of 0.1-N KBr are added to each solution. B gives a thick precipitate, whilst A remains clear at first, and then becomes opalescent. Sheppard and Trivelli have investigated the matter qualitatively and the results are shown in the following curves. (Fig. 5.)

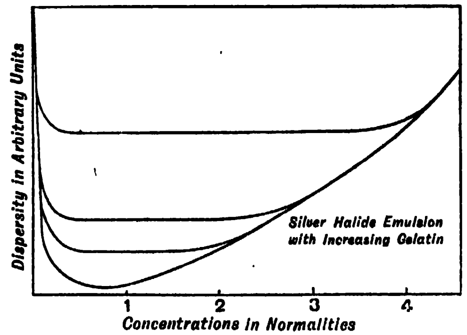

FIG. 5.

It will be seen that with increasing concentration of gelatin: (a) the range over which the initial dispersity is independent of the concentration of the reactants is increased; (b) the dispersity of the precipitated halide is increased. In other words, by varying the concentration of the gelatin it is possible to alter the grain size for one and the same quantity of silver halide.

This effect of the gelatin is due to what is known as its protective action; the gelatin prevents the agglomeration of smaller particles to large ones, whereby precipitation would be produced. Zsigmondy has proposed a method of measuring the protective power in this respect of a colloid. If a solution of sodium chloride is added to a red gold sol the colour of the latter will change to blue, owing to the increase in the size of the particles; the presence of a sufficient quantity of an emulsoid will prevent this change. Zsigmondy defines as the gold number the number of milligrams of colloid just necessary to prevent 10 cc. of a standard gold sol from changing colour when 1cc. of a 10% solution of sodium chloride is added. This gold number varies considerably with different colloids; for example, it is 0.005 for gelatin, 0.01 for

---

* This maximum size of particles at intermediate concentrations may be a secondary effect, due to aggregation of primary particles. According to Odén the degree of dispersion of the primary particles of precipitates decreases uniformly with decrease in concentration of the reactants.

casein, 0.2 for gum arabic, about 10 for dextrin, etc. Sheppard and Elliott have investigated the gold numbers of photographic gelatins, but did not find it possible to differentiate them in this manner. In this connexion it should be borne in mind, however, that the protective action of different emulsoids will vary with the nature of the suspensoid, so that the figures obtained for gold sols will not necessarily be valid for other suspensoids. Gelatin, however, seems to be the most effective protecting agent for the silver halides, as illustrated by the following experiments due to Lüppo-Cramer. To 100 cc. of a silver bromide sol (prepared by mixing very dilute solutions of silver nitrate and potassium bromide), 5 cc. of (a) water, (b) 5 per cent. dextrin solution, (c) 5 per cent. gum arabic, (d) 5 per cent. gelatin, were added. To these solutions were then added 10 cc. of a 10 per cent. solution of sodium sulphate. In case (a) the colloidal silver bromide was coagulated and precipitated immediately; in case (b) the gel formation took place after a few minutes, but sedimentation occurred after 1-2 hours; in cases (c) and (d) gel formation took place with extreme slowness.

A further complication in protective action arises from the fact that it is dependent to some extent on the coagulating electrolyte added. Thus, in the above experiments, when ammonia was used in place of sodium sulphate, the protective action of gum arabic and gelatin was very little greater than that of dextrin; albumin was found in this case to have a much greater protecting action than gelatin.

As has already been stated, the ordinary photographic emulsion in gelatin is made by taking an excess of bromide over the equivalent of the silver nitrate used. This affects the silver bromide in various ways one of which comes into play during the precipitation, and the other during the digestion of the emulsion. When silver halide is precipitated from solutions of medium concentration by a sufficient excess of the alkali halide, it settles out without the supernatant solution remaining cloudy. If the precipitate is collected on filter paper and washed, it is found that when most of the excess of soluble halide has been removed the filtrate begins to run through cloudy, owing to the formation of a hydrosol, i.e., a sol with water as dispersion medium, of the silver halide. This phenomenon takes place most readily with silver iodide and least readily with silver chloride, silver bromide occupying an intermediate position. If exactly equivalent proportions of the silver and halide solutions are used there is no formation of a sol; as already mentioned this is also the case when a large excess of the halide is used. The formation of the sol under conditions such as the above is called peptisation and is due to the adsorption or surface condensation of halide ions from the excess alkali halide, whereby a negative electric charge is given to the particles, thus conferring stability upon them. This phenomenon is particularly interesting in the presence of gelatin, as shown by the following experiment due to Lüppo-Cramer. To 20cc. of O.3N potassium bromide solution are added 10 cc. of 0.6N silver nitrate solution; the precipitated silver bromide is collected and washed. 50 cc. of 10% gelatin solution at 50°C and 2 cc. of 10% potassium bromide solution are then added to the washed silver bromide and the whole well shaken; after 5-10 minutes a homogeneous, creamy, and almost white emulsion is obtained which can be filtered through thick flannel without leaving a residue. If the extra addition of potassium bromide is not made, the silver bromide remains suspended in larger particles, no peptisation takes place. The particles in the creamy emulsion are not sub-microscopic in size, but similar to those occurring in a lantern slide emulsion.

The influence of the gelatin is still more striking if much larger quantities of potassium bromide are added, for example, 10 times the above quantity. In the absence of gelatin the supernatant liquid over the precipitate is only slightly opalescent, whereas when gelatin is present a creamy emulsion results in a few seconds. The gelatin counteracts the coagulating effect of a large excess of bromide ions.

The peptising effect of a slight excess of bromide ions is much exceeded by that of ammonia. If 2 cc. of ammonia solution (d=0.91) are used instead of the 2 cc. of 10% potassium bromide in the above experiment, the silver bromide is immediately dispersed to a creamy emulsion in the gelatin.

It must be borne in mind that the peptisation of the silver bromide only takes place readily when it is freshly precipitated, that is, when it is in a condition analogous to that of a gel. On keeping for a day or so, or on boiling for 5 minutes under water, the precipitate changes to a more stable condition, becoming more powdery and less voluminous, and it can then no longer be peptised. Also, silver bromide which has been precipitated from ammoniacal solution, or which has been precipitated in the absence of ammonia and then shaken with a dilute solution of ammonia, can no longer be dispersed in gelatin by the aid of ammonia or bromide.

The peptising effects of bromide and ammonia in the presence of gelatin at the moment when precipitation takes place are soon superseded by other effects which occur during the digestion of an emulsion. Just as silver bromide freshly precipitated from aqueous solution slowly changes from the gel to a more stable form, so does the silver bromide in the photographic emulsion change, the alteration being accelerated by the temperature of 35-40° used in digestion. The original emulsion is practically grainless and but little sensitive to light, but during digestion it passes slowly into an emulsion in which relatively large grains are distributed more or less evenly through the gelatin. The increase in size of the grains is not due to the coalescence of smaller grains into large ones, although clumping together of grains may take place to some extent, but to the growth of relatively larger grains at the expense of smaller, the process being what is known as Ostwald ripening. Just as a small drop of liquid has a higher vapour pressure than a large one, so, below a certain limit of size, the smaller grains are more soluble than the larger ones. Now silver bromide is soluble to some extent in an excess of potassium bromide, and therefore when grains of different size occur together in the presence of this latter salt, the smaller grains will dissolve and the solute will then separate out on the larger grains. In the neighbourhood of the larger grains therefore the smaller ones will disappear and if the process is so conducted that the grains are kept *in situ*, the larger grains will become surrounded by a clear zone. This is illustrated by the accompanying microphotograph (Fig. 6.) due to Lüppo-Cramer. This effect of potassium bromide is, however, probably small in comparison with that of the ammonia which is added to the emulsion, and which is a much better solvent for silver bromide than is potassium bromide. The effect of ammonia in increasing grain size is shown by the following experiment, due to Lüppo-Cramer: 300 cc. each of a 10% gelatin solution, the one containing 4.5 grams of potassium bromide and the other 6 grams of silver nitrate are mixed at 35° C; an almost grainless emulsion is obtained, which is clear and transparent. If, to a little of this emulsion some ammonia is added and the mixture heated to boiling, it soon goes white and cloudy, showing that a larger grain has been produced. Generally speaking, accompanying the increase in size of the grain there is a corresponding increase in sensitivity of the emulsion. At one time it was supposed that there was a definite connexion between the size of the grain and the sensitivity, but this is now known not to be necessarily the case. A high speed emulsion is prepared in a different way from one of low speed, and the latter cannot be transformed into the former by methods which increase the grain size. The increase in size may only be a concomitant factor with the one which produces speed, that is to say, in the methods used for producing high sensitivity it so happens that increase in size of the grain takes place at the same time as production of speed.

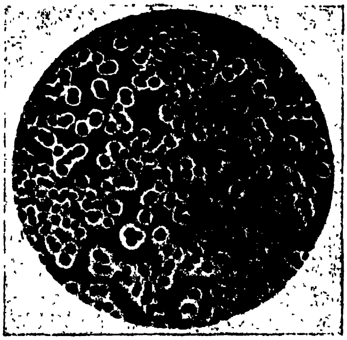

FIG. 6.

The effect of various substances on the swelling of gelatin is of importance in the process of washing the shredded emulsion in order to remove soluble salts. This is usually done with tap or spring water, both of which contain magnesium and calcium salts. Very small quantities of these have an enormous effect in repressing swelling and consequently the gel does not increase in volume to undesirable proportions. The use of distilled water would not only be very costly, but the emulsion would swell so considerably that not only would its characteristics be much altered, but the succeeding operations would have to be very much modified. It is quite possible that when an emulsion is allowed to swell to too great an extent there may be washed out of it substances which would otherwise have an effect in the subsequent process of ripening. Hitherto, however, nothing has been published on the subject.

The extent of the swelling is also conditioned by the temperature, being favoured by an increase in temperature. It is therefore important to control the temperature during the washing process.

The amount of swelling of the washed emulsion affects its viscosity when it is melted, and also the readiness with which it sets; these properties play an important part in the coating process. At the temperature of coating, which is usually near 35-40°C, the emulsion must flow readily, so as to give an even coating on the plate, film or paper, but after the coating is complete it must also set very quickly to a firm film when cooled to a low temperature. In the first operation of emulsion making the gelatin undergoes degradation to some extent and this not only lowers the viscosity but also the readiness with which it sets. Actually, however, the gelatin used in emulsification is usually only a small fraction of the gelatin contained in the finished emulsion and hence it is the viscosity of the bulk of the gelatin used which controls the coating speed and the setting. The viscosity of a gelatin sol decreases very rapidly with rise in temperature, and evidence had accumulated in recent years that this may be due to the breakdown of a definite structure which exists to some extent even in the sol. It is probable that below 34-35°C the sol contains some gel-form, that is, gelatin molecules united to give a structure, but that above this temperature the gel-form has completely disappeared, and a very mobile liquid is obtained. This may be one reason that a temperature of 35-40° is suitable for coating; higher temperatures cannot be used since the sensitivity of the emulsion would be affected. The formation of structure in the sol has its effect on the setting point. A given gel melts at a higher temperature than that at which the sol sets (Fig. 7.) the difference in temperature being probably conditioned by the fact that the formation

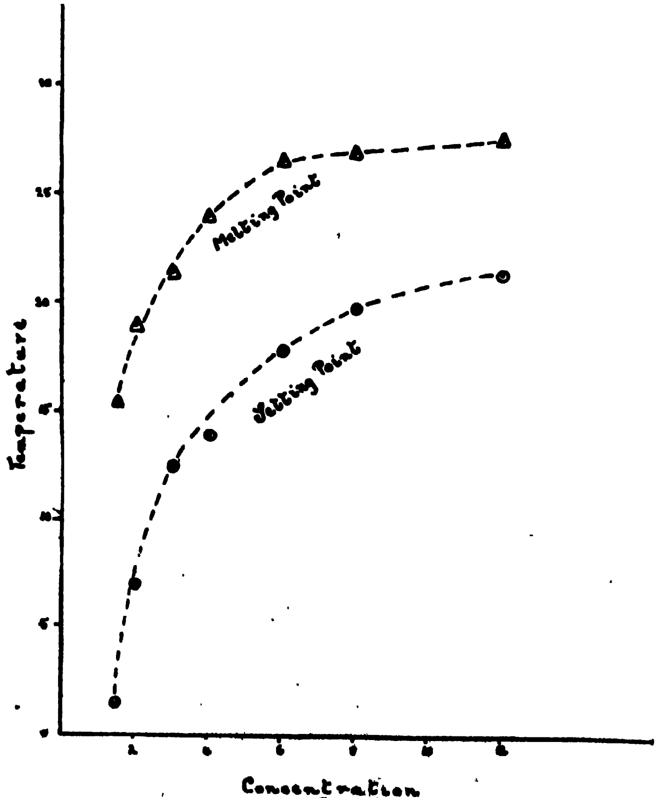

Fig. 7.

of structure takes place slowly and causes a lag in setting when the sol is cooled. Evidence for this slow building-up of structure, both in the sol and in the gel conditions has been obtained in various ways, for example, by investigations of the Tyndall phenomenon; by the change in viscosity of a sol with time, etc.

Just as is the case with other physical properties, the melting and setting points of gelatin are dependent on the content of dissolved salt, acid or alkali; they are controlled to a large extent by the pH, which must therefore always be carefully adjusted; with most photographic gelatins, however, the pH lies between 4.5 and 6.5 and between these limits there is not much variation in the properties mentioned.

The melting and setting points are raised, and the viscosity increases very rapidly, with increase in concentration of the gelatin (Fig. 7.), the rate of increase with concentration being dependent on the pH. These factors necessarily play a part in fixing the limits of concentration of gelatin between which good working results can be obtained. Actually, these limits have been arrived at by the method of trial and error, and usually lie between 6 and 7% of gelatin.

NOTES ON BOOKS.

Civil Engineering Geology. By Cyril S. Fox.
London: Crosby Lockwood and Son. 18s. net.

This handsome large-octavo, with its fourteen plates and nearly a hundred illustrations in the text, is largely a study of fundamentals as regards positions for foundations, whether for vertical or oblique support; there being also a due consideration of the suitability of natural materials for constructive purposes.

Wide experiences in India enable our author to speak with personal authority as to many of the less known aspects of the earth's crust, also to depict and study extreme examples of such conditions as ordinarily affect building and civil engineering in other countries: thus casting new and vivid lights on everyday practice.

The frontispiece, for example, represents a wonderful folding of strata in which we see the border of a reverse fold as it outcrops on a high ridge in a wild and rocky region of Afghanistan: the outcrop appearing almost like the edge of an Elizabethan collar or ruff. Turning now to pages 15, 16 and 47, the reader will find scheme-drawings of comparable folded strata in more modest dimensions and in more everyday aspects; while on pages 44-46 Mr. Fox shows how such strata may impose a shearing or twisting stress on a tunnel or other work passing through, especially when the infiltration of water steps in as a factor.

Part I of the work consists of five chapters, embodying the various aspects in which the civil engineer or builder must study water, whether as a serviceable material in relation to work, or as an uncertain and insidious foe in relation to underground matters. It is instructive to study our author's infiltration diagram on page 20, and his demonstrations as to the influence of stratum-faults on artesian conditions (pp. 24-25); while his account of water difficulties overcome by the genius of Robert Stephenson when constructing the Kilsby tunnel near Rugby, followed by an abstract of Baldwin-Wiseman's teachings on pressure and porosity (p. 30), well illustrate the thoroughness of the book.

We hear much as to the instability of buildings in London owing to the slip of water-lubricated strata, and although the alarmist stories as to St. Paul's may have no firm basis, in fact, there can be no doubt as to the state of Waterloo Bridge: probably owing to the scouring away of the lateral support of the foundations by the deepened and constricted stream. The thorough consideration of water matters by Mr. Fox rather suggests that the engineers of our day may well consider whether the time has come for a fundamental change as regards substructure, in the case of the more important new bridges. Gwilt, on p. 513 of his Encyclopædia of Architecture (Longmans, 1842) shows the inverted arch foundation suggested by "Our Master" Leo Battista Alberti, and on p. 134 Gwilt says that Alberti's book *De Re Edificatoriâ* "is the foundation of all that has been since written on the art." If this principle were put into practice in conjunction with modern methods of tunnelling the result would be a bridge nearly symmetrical above and below, and probably resting on a broader beam or bed of reinforced concrete: this beam having a bore or passage for observations on strain and flexion. It is interesting to note that Gwilt (p. 512) suggests the reinforcement of concrete foundations with embedded iron.

In a review it is not practicable to give an adequate idea of the full scope, detail or contents of a work like that now before us; but this valuable addition to technical literature seems to be equally suitable for use as a first book by the architectural student or as suggestive reading for the matured practitioner.

THE ST. ETIENNE RIBBON INDUSTRY.

Long before the industrial city of St. Etienne was noted for its production of coal and iron, it was known as one of the chief ribbon markets of the world. The beginnings in the 16th century were small. About 1680 the number of handlooms increased from 700 to 10,000 and the industry was very prosperous. In less than a hundred years, however, foreign competition had greatly crippled it, for Switzerland and Austria had begun to utilise mechanical looms which turned out 30 pieces of ribbon at a time. Several St. Etienne manufacturers then brought over some Swiss looms, and soon regained the lost preponderance. Later, the invention of the Jacquard loom occasioned another era of great prosperity. The number of manufacturers increased to 190, and has remained at about this figure.

Toward the end of the 19th century an event of great importance was the installation of electric motors in factories and in the homes of the weavers. At present, 12,360 home looms are operated by electricity, as compared with 6,604 in 1900.

From a recent report by the United States Consul at St. Etienne it appears that practically everything that the ribbon trade can offer is manufactured there, including a series of articles always in vogue, used by confectioners and needlework shops, and also ribbon for lingerie, corsets, shoes, garters, men's hats and suspenders, and other purposes. Recently, since the commodity has been less in vogue, the manufacturers have devoted themselves to the production of silk piece-goods and other silk products, which Lyons has always more or less monopolised. Now, in novelty silks, St. Etienne begins to rival that city, because of its long experience in combining designs and colours.

The aggregate production value of silk and velvet ribbons and silk piece-goods during 1923 increased by 83,948,755 francs, as compared with the figures for 1922, according to statistics issued by the Ribbon Manufacturers' Association of St. Etienne. One of the notable features of the industry was the large increase in the employment of artificial silk in the manufacture of ribbons and silk piece-goods. Among items showing outstanding increases in production compared with 1922 were articles made of artificial silk, 21,820,190 francs; fancy ribbons, pure silk and mixed, 23,502,737 francs; and articles made of cotton, 8,201,173 francs. The total value of the production in 1923 is estimated at 378,182,694 francs, and the value of the home consumption is given as 226,952,412 francs.

The direct exports of ribbons during the year were valued at 151,230,280 francs.

THE LACE INDUSTRY OF TONKIN.

The lace industry in Indo-China is only 20 years old. It was introduced by the French and to-day is centred in Tonkin, although the natives of Cochin-China, Laos, and Annam are beginning to produce for local consumption.

According to a report by the United States Consul at Saigon, it is estimated that 4,000 Tonkinese—men, women, and children—are engaged in the manufacture of lace. Hanoi is the centre of the industry, and it is there that European export houses procure their supplies. The industry was started, and has been fostered, by the French. All the designs and styles of lace are furnished by the export houses, the natives having none of their own. The laces manufactured in the villages are either sold in the hotels and cafés or used locally. All the lace exported to France is made to order. The various kinds of lace manufactured in Tonkin for the export houses are: Craponna, Cluny, Venice, Irish, and embroideries on filet of linen thread or of cotton meche. The filet laces are particularly popular on the French market, the other kinds not being produced so successfully. Thus, far, the natives have not been instructed in making Bruges or Valenciennes laces.

It is difficult to determine the importance of the industry, as the greater part of the exports are taken by tourists or sent out of the country by parcel post. However, the Customs declare that the value of the lace sent from Tonkin to France by steamer in 1922 amounted to 2,835,000 francs. It is estimated that the value of the lace taken out of the country in other ways amounted to an equal figure. It would seem, therefore, that the industry, in approaching an annual export value of 6,000,000 francs, is becoming an enterprise of some importance. Furthermore, considering the abundance of cheap labour existing in Tonkin, and the fact that cotton and silk are also produced in the country, it may assume still greater proportions.

THE IMATRA (FINLAND) POWER SCHEME.

In his annual report on the commerce and shipping of Wiborg, the British Vice-Consul at that port remarks that the only undertaking in the district that merits notice is that of the power station at Imatra, which is regarded as of national importance. The scheme had its inception in 1900 and took form in the ensuing decade in the course of which a committee was appointed to consider its possibilties. The war put an abrupt end to any prospect of work and, after Finland had gained her independence, a scheme of wider scope, developed at the instance of the Finnish Government, was accepted by the Diet in 1921. This is a far-seeing plan which permits of subsequent expansion as requirements demand. The initial part of the scheme provides for three sets of machinery of a combined 73,000 turbine h.p. or its equivalent of 49,000 high tension kilowatts. The outlay, based on the Government index figure of the cost of living, is estimated at 3,350 marks per one high tension kilowatt or 170 million marks for the early part of the scheme.

The Imatra Rapids can produce 117,000 h.p. and those above at Linnankoski 33,000 h.p. at average water level. When all this latent power is available, 100,000 high tension kilowatts would be employed, and it is calculated that by then the average expenditure will have been reduced to 2,800 F. mks. per high tension kilowatt.

The project provides for the laying down of a main power cable to Wiborg. A second would go to Villmanstrand, thence to Riihimäki, and on to Helsingfors, Abo and Karja. A transmission tension of 110,000 volts would be used. Sub-power stations for distribution are to be erected at points where the current would be most in demand.

The central idea is to harness and bring under one control the electric energy dormant or already developed in the three principal rivers of the south of Finland; the Vuoksi, the Kymi and the Kokemaki. Any existing plant would be brought up to date and it is thought that now is the most favourable time for merging any power stations on these three rivers into the Imatra Scheme.

The supply of this electric motive power will, it is anticipated, effect a considerable economy in fuel expenses, promote trade and assist the more rapid development of the resources of the south of Finland. It is expected that manufacturers will be the main support of the undertaking and that it will yield an adequate return on capital from the outset.

The Finnish Government intend to reserve to the State the full rights over the exploitation of the Imatra Rapids and any others that may be amalgamated with the Imatra Scheme.

The work done at an expenditure of 16 million F. mks. towards the realisation of the scheme in 1923 included the removal of 195,000 cubic metres of earth and rock, of which 150,000 cubic metres were employed to make an embankment. A temporary dam was thrown across half the width of the falls to aid the later erection of a permanent concrete structure. Accommodation for engineers and labourers was provided and 11 kilometres of narrow gauge railway laid down. 450 men are at present engaged. The work is planned for completion in 1927.

PROJECTED DEVELOPMENT OF DUTCH NEW GUINEA.

The opening up of Dutch New Guinea for future colonisation and development of natural resources is contemplated by a large German-Dutch company, recently formed. The Dutch portion of the island covers about 152,000 square miles, of which approximately 77,220 square miles are to be allotted to the new company for a period of 75 years, with the exclusive right to obtain forest, agricultural, mineral, and sea products. The native population of the whole of Dutch New Guinea, however, is to retain its unrestricted right to collect and sell similar products. From reports furnished by the United States Vice-Consul at Soerabaya and by the U.S. Trade Commissioner's office at The Hague, it appears that the company is to be granted a right of preference for leasing land in accordance with the stipulations in force, and preferential rights to licenses for prospecting and developing minerals in accordance with the mining regulations of the Netherlands East Indies.

Owing to the sparse population of New Guinea the labour question is one of the utmost importance. The company is privileged to effect working agreements with the natives, as well as with foreigners whom it may take into its service—possibly Chinese coolies. It has also been suggested that labourers for the cultivation of coconuts will be brought from Japan and the Molucca Islands.

In return for the privileges requested, the company is to pay to the autonomous government of the district fixed excise duties and 10 per cent. of its net profits to the Government of the Netherlands East Indies. It is also to defray the expenses of police protection.

COCA CULTIVATION IN THE NETHERLANDS EAST INDIES.

The cultivation of the coca shrub a few years ago was regarded as one of the most promising industries in the Netherlands East Indies. In 1919 the total area planted reached 7,980 acres. Coca is usually grown among other crops, and, therefore, writes the United States Consul at Batavia, it is difficult to determine the exact area under cultivation. Official statistics, moreover, do not agree as to the number of estates on which this plant is grown. In 1921 an area of 2,998 acres was reported for 16 estates and 29 had coca planted alongside the roads, according to the annual statement of the Department of Agriculture, Industry, and Commerce.

The acreage planted to growing shrubs, the reported production, and the quantities exported during the period 1918 to 1922, inclusive, as stated by the Bureau of Statistics, were as follows:—

Years	Planted area	Reported production	Exports
	Acres	*Pounds*	*Pounds*
1918	6,958	2,549,476	1,456,329
1919	7,980	1,687,591	2,187,247
1920	6,308	1,805,186	3,688,567
1921	2,998	1,599,728	2,502,221
1922	3,512	1,960,717	2,823,707
Total ..		9,602,698	12,658,071

The preceding figures, of course, apply to the dried leaves, and it is apparent that there is considerable production from areas not reported. The production of the "catch crop," planted in single rows along the edges of fields of other crops, is also not reported to the Bureau of Statistics, but the difference between the production of estates where cultivation is carried on in a systematic manner and the exports—amounting to about 3,000,000 pounds during the five years—represents the quantity produced in this manner.

The 1923 exports of coca leaves were some 2,066,000 pounds, according to preliminary figures. The Netherlands was the leading destination in that year, receiving 1,187,400 pounds, compared with 1,987,000 in 1922. Japan came second, with about 800,000 pounds in 1923. The Netherlands is the distributing point for Europe and also probably for a large part of the trade of the United States. The figures for Japan, accounting for more than one-third of the total, indicate that it is one of the leading manufacturers of the drug. No cocaine in manufactured in the Netherlands East Indies.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICE.

INDUSTRIAL DESIGNS COMPETITION.

In accordance with the desire expressed by the Queen on the occasion of her visit to the Society's recent exhibition of Industrial Designs at the Victoria and Albert Museum, Her Majesty has purchased a design exhibited by Mr. William R. Pearson, of Leicester, in the competition for the prizes offered by Messrs. J. S. Fry & Sons, Ltd., for chocolate box designs. Another exhibit of this competitor was awarded a prize given by the same firm in a different class.

PROCEEDINGS OF THE SOCIETY.

COBB LECTURES.

CERTAIN FUNDAMENTAL PROBLEMS IN PHOTOGRAPHY.

By T. Slater Price, O.B.E., D.Sc., F.I.C., F.R.S.

(Director of Research to the British Photographic Research Association).

Lecture II.—*Delivered March* 31*st*, 1924.

The method of drying the coated plate is very important; it must be done under uniform and standard conditions, since it is a well-known fact that during the drying of coated plates a further ripening takes place. Comparatively little work has been published on the drying-down of gelatin gels; it is a question which is intimately bound up with the structure of such gels, and in the case of photographic plates there is the further complication that the gel tends to dry down (and swell up) normally to the surface. The drying-down is, however, not absolutely normal to the surface, and Sheppard, Elliott and Sweet have investigated the lateral contraction which takes place when a gelatin gel is dried down on a rigid support, by using thin aluminium sheet as the support and measuring the curvature of the same after drying to equilibrium with an atmosphere of fixed humidity at a definite temperature. The contraction occurring was found to vary with the origin of the gelatin, such variations possibly being connected with different structures; it was also found to be dependent on the initial pH of the gelatin, being greatest in the neighbourhood of the isoelectric point. Over the range of pH usual for photographic gelatins there was not much variation.

The reverse process to drying-down, namely, swelling, takes place during the operations of development, fixing, and washing. It is the readiness with which gelatin swells and thereby becomes permeable to aqueous solutions which makes it so useful as a vehicle in sensitive emulsions. The swelling must be controlled, however, otherwise such troubles as frilling occur and the gelatin film is liable to come away from the support. It has already been pointed out that dissolved salts, etc., have a very marked influence on the swelling, so that fortunately methods of control are in the hands of the photographer; also, as we shall see, further control can be exerted by hardening the film. One curious fact about swelling is that it depends very much on the previous history of the gel. Bancroft has instanced the following: "Gelatin gels were made containing 8, 16, 24 and 32 per cent. of gelatin; these were all dried at room temperature to about 96 per cent. concentration. When water was added, each swelled rapidly to the original concentration and then took up water slowly. If these results are accurate, it means that the four 96 per cent. gels were all different and that the 8 per cent. gel did not become like the 16, 24, or 32 per cent. gel while being dried." It has been a controversial point as to whether this phenomenon was due to a skin effect or to differences in internal structure, but recently Gortner has brought definite evidence in favour of the internal structure explanation. He finds that if jellies of different initial concentrations are dried, powdered, and swollen in water again, the swelling limit still appears to depend on the initial concentration.

The pioneers of scientific measurements in photography, Messrs. Hurter and Driffield, early studied the swelling of the film on plates, but, using modern methods, Sheppard and his co-workers have recently investigated the problem more carefully. Solutions of ordinary developers, such as pyro, hydroquinone, etc. are alkaline, and, as has already been pointed out, alkalinity increases the swelling of gelatin to such an extent that very undesirable results would accrue were no other substances present to check the swelling. Sodium carbonate is usually the alkaline component of developing solutions, however, and as the following figure (Fig. 8.) shows, when present in 5 per cent. concentration or more it depresses the swelling to a value below that which obtains in water.

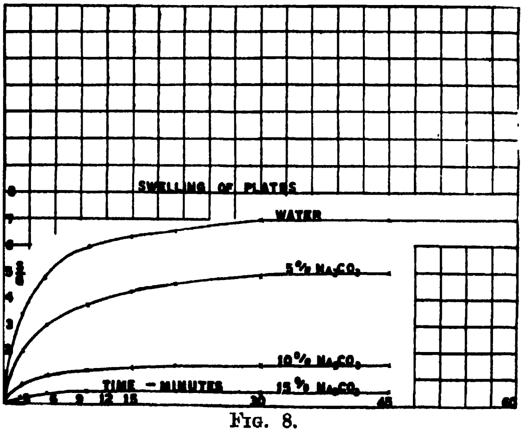

FIG. 8.

Sodium sulphite has an effect similar to that of sodium carbonate, as shown in Fig 9. The same figure shows the effect of each of these in the presence of pyro.

The curves in Figure 9 show that a fairly stationary value of the equilibrium is soon attained, and also that the depressing effect of the salts increases very rapidly with increase in concentration. The latter fact may be made use of in preparing developers for use at high temperatures, as in the tropics.

It should be mentioned that results obtained with the free swelling of gelatin cannot be transferred quantitatively to the swelling when the gelatin is fixed on a rigid support. In the latter case the maximum swelling tends to be considerably less, at the same temperature and pH, than in the former case.

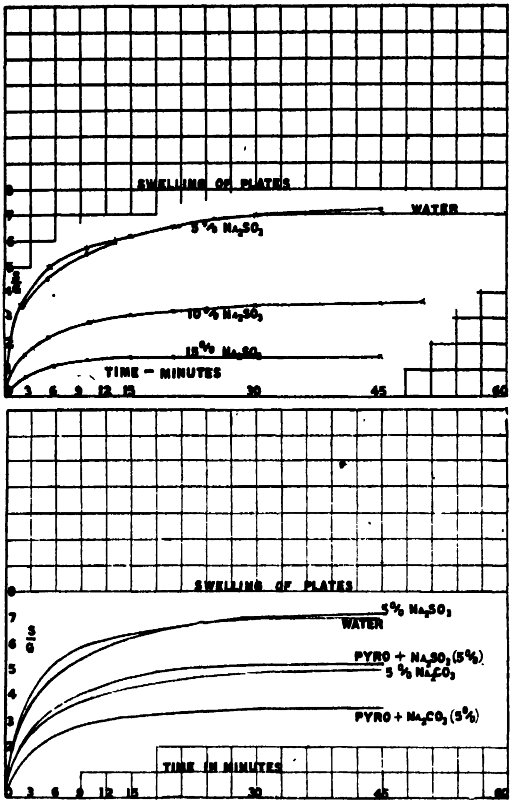

FIG. 9.

Another method of preventing the swelling which takes place at the high temperatures of the tropics is to harden the film before development. For this purpose formaldehyde is a common reagent, which may also be used in conjunction with anti-swelling salts. For example, in a method patented by Ilford Ltd., the formaldehyde solution contains also a salt such as sodium citrate, sodium sulphate, or magnesium sulphate, which, as mentioned previously, depress the swelling of the gelatin. The gelatin is hardened by the formaldehyde because of the formation of an insoluble condensation product. The action is not instantaneous, but increases rapidly with time, and is all the more pronounced the less swollen the gelatin. The beneficial effect of the added salts is, therefore, probably due to the effect they have in preventing the swelling of the film before the formaldehyde exerts its full action.

The prevention of swelling is very important, not only for obviating frilling, which, when very pronounced may lead to the gelatin film floating off its support, but also for stopping reticulation. When the swelling pressure becomes very great the increase in volume normal to the support may not be able to account for it all; lateral or tangential dilation will then take place and if the attachment to the support remains firm the film will pucker or reticulate. Reticulation may give a mosaic effect and is particularly marked after short treatment with a hardening agent, followed by warm water. (Fig 10.)

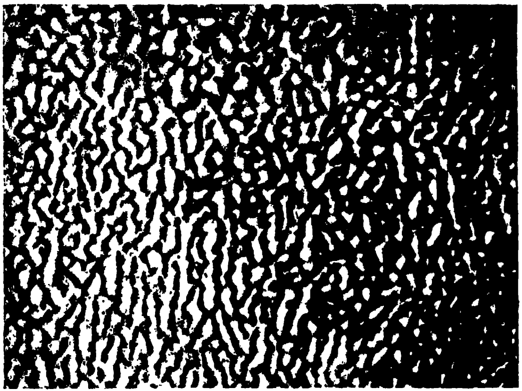

FIG. 10.

The valleys of the reticulations are hardened, whilst the ridges are softer and more swollen; at the same time the latter draw the silver particles into them to some extent, so that the appearance of an image is spoiled.

After development the plate is rinsed and then fixed, which is now often carried out in an acid fixing bath. Since the developer is alkaline, this means that the gelatin must pass through the isoelectric point, where the swelling is a minimum, to some point on the acid side, where the swelling again becomes noticeable. Before dealing with the complication of the acid fixing bath, however, it will be as well to consider the processes which take place when an ordinary fixing bath is used, that is, one containing sodium thiosulphate only. In the first place the time taken for fixation will depend on the rate at which the thiosulphate diffuses into, and dissolves silver halide out of, the film. This is well shown by fixing plates in one case suspended face down, and in the other face up, without stirring or rocking. The face-down plates will be fixed in approximately half the time required for the others. This result with the face-down plate is probably dependent on the down-flow of the heavy reaction products causing convection currents at the surface of the plate, whereby fresh thiosulphate is continuously supplied: this particular effect may be left out of consideration in what follows. The rate of diffusion of the thiosulphate into the film for a given amount of swelling of the gelatin would be all the greater the higher its concentration; also the more swollen the gelatin the more readily will the thiosulphate diffuse into it. Increase in concentration of the thiosulphate however, decreases the swelling of the gelatin, as shown by the sloping curve in (Fig. 11.). There will come a point, therefore, when the effect of the diminished swelling more than counterbalances the effect due to increased concentration of the thiosulphate, that is, there will be a minimum time of fixation. That this is the case is shown by the following curves, (Fig. 12.) due to Sheppard, which indicate that this minimum time is at a concentration of about 30-40% of thiosulphate, a result which had previously been obtained by Welborne Piper, among others. The influence of rise in temperature is also shown by the curves, there evidently being a double effect, namely, increase in rate of diffusion of the thiosulphate and increasing swelling of the gelatin. The effect due to increased swelling may be illustrated by the acceleration of fixing produced by adding to the bath such substances as ammonia or ammonium thiocyanate which increase the swelling of the gelatin; these substances are, however, likely to cause trouble owing to the softening effect they have on the gelatin.

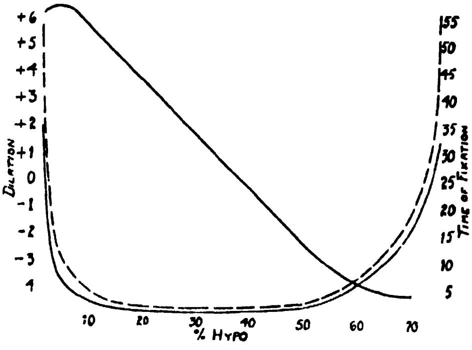

FIG. 11.

We may now consider the acid fixing bath, the constituents of which are: sodium thiosulphate for dissolving the silver halide; sulphurous acid or some organic acid, which acts as a clearing agent, reduces stain and promotes swelling; sodium sul-

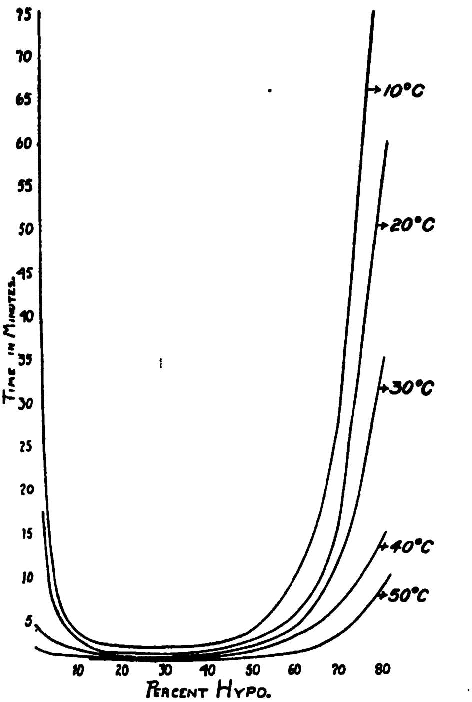

Fig. 12.

phite or meta-bisulphite, which protects the thiosulphate against decomposition by the acid, and also prevents oxidation and hence staining; alum, which hardens the gelatin and prevents frilling, etc.

It will be convenient first to deal with the action of alum as a hardening or tanning agent. It has already been pointed out that concentrated solutions of many salts suppress to a greater or lesser extent the swelling of gelatin. In this sense they may be called hardening agents, but the hardening effect is only temporary, since it is only in action in the presence of these salts and disappears when the gelatin is soaked in water. When such substances as alum are used, however, the hardening is permanent in the sense that it is not reversed by subsequent washing; the gelatin takes up some substance and becomes insoluble.

The explanation of the action of the alums, with which salts may also be classed those of heavy metals, is at first sight, fairly straightforward. It is based on the fact that such salts are hydrolysed in aqueous solution, hydroxide of the metal being formed and acid set free, as, for example, in the case of ferric chloride.

$$FeCl_3 + 3H_2O \rightleftharpoons Fe(OH)_3 + 3HCl.$$

The hydroxide remains in colloidal solution. Hydrolysis being a mass action, it will be increased by dilution of the solution. It is also increased by rise in temperature, as may be shown by the following experiment. A solution of ferric chloride is diluted so that it possesses very little colour, and then divided into two parts. On boiling the one part it becomes very much darker in colour, owing to the colloidal ferric hydroxide formed by hydrolysis.

The increased hydrolysis, on dilution, may be shown by the following experiment due to Lüppo-Cramer. A solution of ferric chloride is diluted with a one per cent. sol of gelatin, when it is seen to assume the same dark colour as the aqueous solution does on boiling, showing the increased hydrolysis. Strictly speaking, however, this is not merely the effect of dilution; the colloidal ferric hydroxide is adsorbed by the gelatin, forming a complex of some kind and thus the equilibrium represented by the equation already given is disturbed and more hydrolysis takes place; there is, therefore, the double effect of the dilution and of the influence of the gelatin.

All ferric salts are hydrolysed in aqueous solution in a similar way to ferric chloride; the same is true of aluminium and chromium salts, and it is with these last-mentioned salts especially that Lumière and Seyewetz have carried out quantitative measurements. They determined the quantities of the sulphate, chloride, nitrate and acetate of chromium respectively which were necessary to render a given amount of gelatin insoluble. When the weights of chromium hydroxide equivalent to each of these quantities of the different salts were calculated, it was found that they were approximately the same. One is, therefore, justified in concluding that it is the chromium hydroxide, formed by hydrolysis, which makes the gelatin insoluble, owing to the formation of a complex of some kind with the gelatin. The acid set free by hydrolysis can be washed out, leaving the hardened gelatin. Treatment of the hardened gelatin with small quantities of acid or alkali will dissolve the chromium hydroxide and the gelatin, then readily swells and dissolves in water. In a similar way it has been shown that the hardening produced by aluminium and ferric salts is due to the hydroxides formed by hydrolysis.

In the above no definite statement has been made as to the actual cause of the hardening of gelatin by such a salt as alum, beyond saying that it is possibly due to the formation of a complex of some kind between the metal hydroxide and the gelatin. According to Loeb, gelatin only combines with metals when its pH is greater than 4.7, and one would therefore conclude that for an alum hardening bath to function properly the acidity of the solution must lie between pH 4.7 and the neutral point, pH 7, between which values an aluminium gelatinate could be formed. The difficulty immediately arises, however, that the pH of a solution of an aluminium salt, say M/10 aluminium chloride or sulphate, is somewhere between 2 and 3. At a pH of 4.7 or more a large proportion of the aluminium would have been precipitated as hydroxide; in fact, results obtained in experiments on the addition of sodium hydroxide to the solution of an aluminium salt indicate that the formation of the hydroxide commences at pH 3 and is complete at pH 7, beyond which the alumina goes into solution as aluminate. Visible precipitation of the hydroxide may not take place until one-third to one-half of the alkali necessary for complete precipitation has been added, but evidence has accumulated that between the limits pH 3 and pH 7 the formation of intermediate complexes takes place, which, with aluminium chloride would pass through stages such as :- $Al(OH)Cl_2$, $Al(OH)_2Cl$, $2Al(OH)_3$, $Al(OH)_2Cl$, etc. There is thus the formation of complex positive ions and the question arises as to whether these may have a hardening effect on gelatin at a pH less than 4.7. The following curves (Fig. 13.) show that such hardening, as measured by the melting point of the gelatin, does take place, the maximum hardening occurring in the neighbourhood of pH 4.0. According to Loeb's ideas this would necessitate the existence of negative gelatin ions at a pH less than that corresponding with the isoelectric point.

It will be seen that a true explanation of the hardening action of alum on gelatin has still to be found. The reaction is really a complicated one and it does not seem probable that Loeb's ideas can be applied without considerable modification. If it is granted that some complex is formed between the aluminium hydroxide, or basic hydroxide, and the gelatin, the latter acting as a regulator of the hydrolysis, the nature of the complex still remains a mystery.

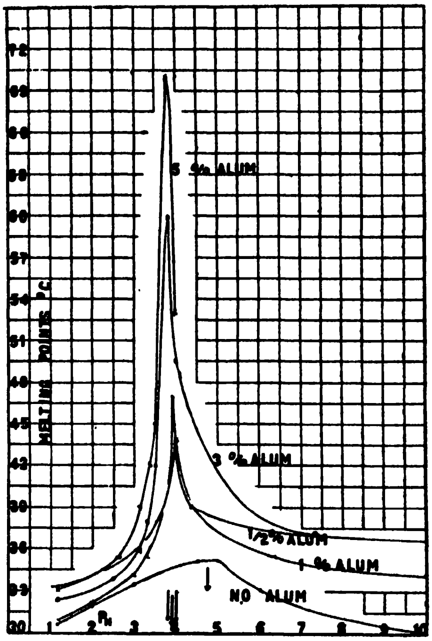

FIG. 13.

Returning now to the acid fixing bath, its acidity generally lies somewhere between pH 4 and pH 5, that is, near to the point of maximum hardening, pH 4, mentioned above. The optimum acidity, however, is not dependent only on the alum, but also on the thiosulphate present. Acids decompose thiosulphate with the liberation of sulphur, as expressed by the equation :—

$$S_2O_3'' + 4^{\bullet} \rightleftharpoons HSO_3' + S.$$

This reaction is represented as reversible and experiment shows that the addition of sulphite, or of metabisulphite, $Na_2S_2O_5$, has a retarding effect on the liberation of sulphur. The exact effect of the sulphite is, however, probably very complicated owing to the formation of salts of the various polythionic acids. Now in the acid fixing bath the pH cannot be much less than 4, otherwise sulphur will be precipitated. For the alum to have its hardening effect, however, the pH must not be greater than about 4, otherwise aluminium hydroxide will be precipitated and the bath will be useless. There thus seem to be two demands which will be very difficult to satisfy at one and the same time, owing to the narrow limits of pH allowable, but this difficulty is overcome by using such organic acids as citric, tartaric, etc., to give the necessary acidity. These give rise to the formation of complexes with aluminium and thus prevent the deposition of aluminium hydroxide, but at the same time a further complication is introduced in that the complexes decrease the hardening action of the alum, as shown in the following (Fig. 14.). Too much organic acid must, therefore, not be used.

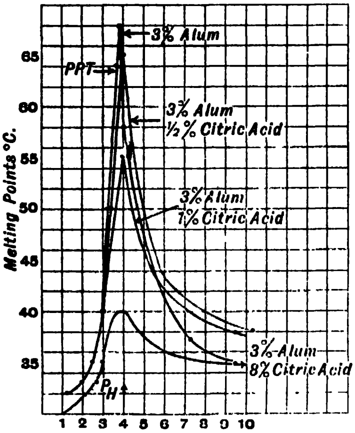

FIG. 14.

The sulphite and thiosulphate present in the bath also alter the pH of the maximum hardening effected by the alum, raising it to values equal to or greater than 4.7.

One other point has still to be considered. The acid fixing bath must have a reasonable reserve acidity in order to neutralise alkali left in the gelatin film after development and rinsing with water; at the same time there is the condition that the pH of the solution must not alter much as this acidity is used up. The acid is also necessary to transform coloured products from the developing solution into colourless acids, so as to remove stain. Such reserve acidity is always attained when, as in the acid fixing bath, there are present a weak acid and its sodium salt. The nature of the phenomenon may be illustrated by the following Fig. 15, which shows how the pH of solutions of acetic acid varies as increasing quantities of sodium hydroxide are added to it, 10 cc. of the hydroxide being equivalent to the acetic acid taken. It will be seen that between 2 cc. and 8 cc. of added sodium hydroxide the rate of variation of the pH is comparatively small, varying between 4.05 and 5.23. After this point the variation becomes very rapid and the acidity rapidly diminishes with added alkali. Thus a solution corresponding with pH 4.05 can have its acid neutralised to a very considerable extent before its pH changes appreciably.

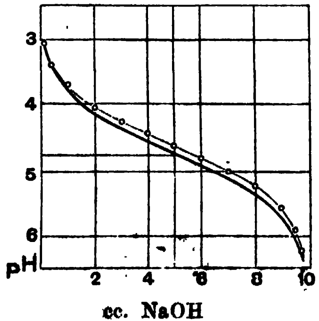

FIG. 15.

From the above it will be seen that the action of the acid fixing bath is a very complicated one, and although it was introduced by Lainer in 1889, and made up empirically, its exact action still awaits explanation. A compromise has to be made between the various requirements and this compromise results, to some extent, in a diminution in the hardening effect of the alum. Where satisfactory hardening is required it is best to use a separate hardening bath.

Naturally the removal of excess thiosulphate, etc. from the fixed plate by washing with water is affected by the swelling of the gelatin and hence by the hardening. The process is one of diffusion, consequently the method of bringing the plate into contact with the washing water and of renewal of the latter is of very great importance. Want of space, prevents however, discussion of this question.

It is now necessary to give some discussion of the part which gelatin plays in the process of development, and also in the grain itself. In the first place, however, reference must be made to the reduction of silver halides, especially the bromide, in the absence of a medium. For a long time there was considerable controversy as to whether medium-free silver bromide was not instantaneously reduced by a developer. The question was settled, however, when several different observers showed that it was possible to prepare medium-free plates from silver bromide precipitated from aqueous solutions in the dark, and, after exposure, to develop them with suitably restrained developers and obtain an image. The production of an image indicated that the unexposed silver bromide was not reduced by the developer in the time necessary to reduce the exposed halide.

The divergent results which were first

obtained by different investigators were probably due to differences in the silver bromide used, as is indicated by the following experiments of Lüppo-Cramer. 400 cc. of 3/200-N silver nitrate were added, in non-actinic light, to 400 cc. of an equivalent solution of potassium bromide, whereby an opalescent sol of silver bromide was obtained. When 10 cc. of a metol-soda developer were added to 200 cc. of the fresh sol, reduction to silver was only noticeable after 10-15 minutes, and after that time proceeded only very slowly. If, however, the sol had been exposed to daylight for a few seconds, the addition of the developer apparently brought about instantaneous reduction. Further, if electrolytes were first added to the unexposed sol in order to decrease the dispersity, reduction took place within a few seconds of adding the developer, whilst a sol which had been kept for three or four days and had partly precipitated was reduced immediately. Schumann, in experiments on so-called grainless emulsions, had also found that the coarser the precipitate of medium-free silver bromide, the more readily it was reduced.

The fact that the fresh sol is not so easily reduced as one which has aged to some extent is an anomaly in itself. The more finely divided a precipitate is the greater is its surface energy and consequent reactivity, so that one would expect the fresh sol to be more readily reduced. Also, a freshly formed precipitate is often in a metastable condition and much more reactive than when it has changed to the stable condition. It is possible that the phenomenon is affected by adsorption reactions, and it would be worth while to repeat the experiments under strict conditions. It is interesting to note that according to Weisz, silver bromide precipitated from aqueous solution is more sensitive to light the finer the grain.

In contrast with the medium-free compound there is no doubt as to the retarding effect of gelatin on the reduction of silver bromide, since it is this effect which has made the gelatin photographic emulsion a possibility. Various instances could be given to show that the viscosity of the medium has an influence on chemical reactions, and at one time, as especially instanced in the older literature, it was supposed that it was due to some mechanical influence of the gelatin that the reduction of unexposed silver bromide was prevented in its presence. Such an explanation cannot, of itself, be sufficient, however, since it has been found that quantities of material insufficient appreciably to affect the viscosity of water produce a pronounced retardation. Thus Reinders and Nieuwenburg found that the rate of reduction of finely crystalline silver chloride by ferrous citrate was appreciably retarded even in the presence of 0.001% of gelatin; retardation was also observed in the presence of certain dyes which in themselves, would have no effect on the viscosity of the solution.

It is, of course, possible that in the presence of gelatin the rate of solution of the grain may be considerably retarded, and this would slow down reduction. This, however, would not explain why the exposed grain which has undergone no visible change reduces so readily. Moreover, Reinders and Nieuwenburg showed that the velocity of solution of silver chloride in ammonia is not altered in the presence of 0.2% of gelatin. In this connexion, however, it should be pointed out that Peskoff has shown recently that gelatin has an enormous influence on the rate of solution by potassium hydroxide of such colloids as arsenic sulphide and also that it affects the rate at which secondary aggregations are broken down into primary particles.

There is, however, another way in which gelatin can have an effect. It has been shown by Marc that colloids, including dyes, cause a very marked retardation of the rate of crystallisation of supersaturated solutions. When the reduction of silver bromide by the developer takes place the silver first formed will be in solution or in the form of amicrons—particles smaller than can be observed in the ultramicroscope. If nuclei of silver are already present in the grain, as is supposed to be the case after it has been exposed, this reduced silver in the solution can then deposit on them and so the image will be built up; the rate of deposition will, however, be considerably retarded by the gelatin, that is, the apparent rate of reduction of the silver bromide, as measured by the deposition of silver, will be much less than that of medium-free bromide. In the case of the unexposed grain there are no silver nuclei, and, therefore, deposition of silver from the solution cannot take place. This is substantially the explanation given by Lüppo-Cramer and Reinders, but there are difficulties in the way of accepting it for the unexposed grain. If the gelatin does not retard the solution of the grain, reaction between the dissolved silver bromide and the developer will go on as usual, and if no deposition of silver takes place there must ultimately be a supersaturation so great with respect to it, that it is difficult to postulate its existence. One way out of the difficulty is to suppose that the supersaturated silver tends to reverse the reduction reaction, and so its increase in concentration is limited; a mechanism of this kind would be favoured by the protecting action of the gelatin, which prevents the agglomeration of the amicrons to the larger particles which would separate out as nuclei. This is analogous to the theory of Mees and Sheppard that the function of the gelatin is to act as a filter against nuclei. Even in this case, however, nuclei will form after a time, so that deposition of silver will take place and there will be general fogging, as is known to be the case with prolonged action of the developer.

It is well known that the silver produced by development of photographic plates and papers may vary in tone from a deep black to a greyish-white, and also that it may have colours ranging over the visible spectrum. Dealing first with the black tones, attention may be called to some experiments of Lüppo-Cramer, who has published a considerable amount of work on the subject. In his early experiments he came to the conclusion that when the silver results from a very rapid reduction of its compound it separates in a very finely divided condition (the A-form) and is consequently black, whereas when the rate of reduction is slow the particles are much coarser, owing to Ostwald ripening having time to come into operation, and hence the colour is lighter, tending to greyish-white (the B-form). This difference in the size of the particles is evidenced by the fact that the A-form is quickly bleached by a solution of mercuric chloride, whilst the B-form turns only a dark colour with the same reagent.

Later investigations did not confirm the above-mentioned conclusion that the varying colour was due to a difference in the size of the particles, as is shown by the following: To 100 cc. of a 2% solution of purified gelatin were added 4 cc. of a 10% solution of silver nitrate, 10 cc. of a 1% solution of potassium citrate, and then 4 cc. of a 10% alcoholic solution of hydroquinone. The silver citrate first produced was reduced to silver, which was deep black in reflected light. A similar experiment in the absence of citrate gave a silver which was light grey in reflected light. Microscopic examination of these two forms of silver showed that there were no characteristic differences, either in shape or in size. Nevertheless there was a difference in the internal structure of the separate particles, since the black silver was much more quickly bleached by mercuric chloride than was the grey silver. The difference in colour of the two forms of silver is, therefore, really due to a difference in the internal dispersity of the particles. In the production of the black silver the silver citrate first produced is colloidal, and probably, as long as it is present, has a protecting effect, in addition to that of the gelatin, on the silver as it is formed.

These different forms of silver play a part in ordinary photographic practice. For example, the addition of soluble bromides to a developer in order to reduce the effect of over-exposure has a considerable influence on the character of the reduced silver. If large quantities of bromide are present, development is much slower and instead of the ordinary black silver the light-grey form is produced. It is possible that the effect of the bromide is not simply due to the retardation it has on development, but that it diminishes to some extent the protecting action of the gelatin, since it is known that bromides lower the melting and setting points, and viscosity of gelatin.

Even in an ordinary negative the silver in the various parts varies in dispersity; when treated with mercuric chloride solution the shadows, which consist of the most highly disperse silver, begin to bleach first, then the middle tones, and finally the high lights. This order of reaction is not always the same with different reagents; for example, when the image is reduced with persulphate the high lights are first attacked. This apparent anomaly is due to the fact that during the fixing the image may adsorb impurities from the bath or be attacked and changed to some extent by the fixing agent; whatever action takes place will be the more marked the more highly disperse the silver. It follows that the silver in the high lights remains the most pure, and as regards the action of persulphate, it is then the more readily attacked. It should be mentioned that other explanations of this action of persulphate have been given.

Beside the black tones of the ordinary image, it is well known that coloured images may be obtained directly by appropriate methods of development. These colours are analogous to those obtained with silver sols in which the particles vary in size. A large amount of work has been published on coloured silver sols containing gelatin as protective colloid, especially by Lüppo-Cramer, but the most exact observations have been made comparatively recently by Schaum and his co-workers. They prepared what is known as a nucleus sol, containing very highly dispersed silver, according to the following modification by Lüppo-Cramer of Carey Lea's original method. 10 cc. of a 10% solution of yellow dextrin, 10 cc. of 10% sodium hydroxide, 7.5 cc. of 10% silver nitrate, and 22.5 cc. of water are mixed, the mixture being diluted to 1500 cc. after half an hour. This nucleus sol is practically optically clear, transmitting brownish-red light which becomes pure yellow in very thin layers or on high dilution. To a definite quantity of the nucleus sol were added successively definite quantities of a 1% solution of gelatin, followed by definite volumes of solutions B and A, solution A being added last. Solution B consisted of 2 grams of crystallised sodium sulphite and 2 grams of *p*-phenylenediamine dissolved in 100 cc. of water, and solution A of 18 grams of crystallised sodium sulphite and 0.75 gram of silver nitrate dissolved in 100 cc. of water. The various sols were then obtained as in the following table, which also gives the colours in transmitted (T) light before and after dilution.* In this method of preparation each sol contains particles from the preceding sol as nuclei on which deposition of silver can take place. As we proceed from sol 1 to sol 7, therefore, the particles should increase in size, and in accordance with this it is found that the strength of the Tyndall cone increases in the direction 1 to 7.

The relation between colour and the size of the particles in suspensoid sols of metals is a very complicated one, since in the passage of light through the sol some of it is absorbed by the particles and some of it scattered. In his work on gold sols Steubing has shown that for particles 20 $\mu\mu$ in diameter the scattering is very small, and for particles of 2-4 $\mu\mu$ it is immeasurable. Such sols, therefore, behave towards light in the same way as true solutions of dyes, that is, the colour of a very highly dispersed sol is not that of a turbid medium, analagous to that of the blue colour of the sky, but is due to a specific absorption by the particles of the dispersoid, which absorption can be calculated from the optical constants of the particles and will depend on their size. In such sols the relation between the colour of the transmitted light (subjective colour) and that absorbed is given by Table A, due to Wo. Ostwald.

In the silver sols prepared by Schaum the particles are larger than 20 $\mu\mu$ in diameter, their sizes, as measured in the ultramicroscope after stabilising the sols in gelatin, being found to vary from 70 $\mu\mu$ in the orange coloured sols to 180 $\mu\mu$ in the blue-green sols. The relation between the subjective colour of the sol and the colour of the particles as seen in the ultramicroscope, which corresponds with the absorbed colour in the above table, will, therefore, be somewhat modified, but, as shown in table B, there is an approximate agreement between theory and experiment.

Nucleus sol.	1% Geln. cc.	Soln. B. cc.	Soln. A. cc.	T.	T (after dilution)
I. 0.2cc.	9.2	0.2	0.4	Orange-red	Yellow
II. 5cc. of sol I.	4.5	0.1	0.2	Deep red	Yellow-orange
III. 5cc. of sol II.	4.5	0.1	0.2	Deep red	Orange
IV. 5cc. of sol III.	4.5	0.1	0.2	Dark red	Orange red
V. 5cc. of sol IV.	4.5	0.1	0.2	Purple	Red violet
VI. 5cc. of sol V.	4.5	0.1	0.2	Blue violet	Blue violet
VII. 5cc. of sol VI.	4.5	0.1	0.2	Blue green	Blue green

Having dealt with the way in which silver sols of various colours can be obtained when gelatin is present as a protecting agent, the colour effects which are produced by development may now be considered.

---

* For demonstration purposes the coloured sols are best prepared by Lüppo-Cramer's method. To 500 cc. of a 2% solution of purified gelatin are added 20 cc. of a 10% silver nitrate solution. To separate quantities of 100 cc. of this solution, warmed to 30°, are then added respectively (*a*) 0.5 cc. (*b*) 2 cc. (*c*) 5 cc. (*d*) 10 cc. of a fresh nucleus sol prepared as in the text, followed by 0.5 cc. of a 1% solution of sodium phosphate and then 4 cc. of a 10% alcoholic solution of quinol. After 20 minutes the transmission colours are (*a*) blue, (*b*) violet, (*c*) red, (*d*) yellowish red. If the sols are diluted with an equal volume of 10% gelatin, coated on glass and dried, the colours become finer and are displaced towards the blue end of the spectrum. In order to obtain a dry, red film, it may be necessary to use 20-30 cc, of the nucleus sol.

Table A.

Wave length in $\mu\mu$	700	650	600	550	530	500	480	450	430	400
Absorbed colour	Purple	Red	Orange	Yellow	Green yellow	Green	Green blue	Blue	Indigo	Violet
Subjective colour	Green	Green blue	Blue	Indigo	Violet	Purple	Red	Orange	Yellow	Green yellow
Wave length in $\mu\mu$	500	480	450	430	400	700	650	600	550	530

Table B.

Sol.	Subjective colour of diluted solution.	Colour of particles.	Absorbed colour according to table.
I.	Yellow	Weak bluish-violet	Indigo*
II.	Yellow orange	Weak blue	Blue
III.	Orange	Stronger blue	Blue
IV.	Orange red	Chiefly blue ; some blue-green and orange	Blue-blue green
V.	Reddish-violet	Many blue-green, orange and red†	Blue-green
VI.	Bluish-violet	Chiefly orange and yellow	Yellow-green yellow
VII.	Bluish-green	Yellow and White	Red

* This, as a spectrum colour, may be classed as bluish violet, since many observers cannot distinguish an indigo in the spectrum.

† Evidence was obtained that the red of these particles was a contrast colour, and not real.

Whenever the developer contains a solvent for silver halide the rate of development is very much diminished and there is a tendency for the formation of coloured silver. This latter may be deposited in the form of what is known as dichroic fog, or else a coloured image is produced. This image in some cases, at all events, probably consists of black particles of microscopic size in conjunction with the coloured silver sol, since brown and sepia tones are not formed in the true silver sols. It has long been known that if lantern slides, which contain a fine grained emulsion, were developed with a developer containing ammonium carbonate as a silver halide solvent and ammonium bromide as a restrainer warm tones in sepias and browns were obtained. It was shown by Mees and Wratten in 1909, who used the ultramicroscope in their observations, that at the commencement of development a yellow tone is obtained, which is succeeded by reds, browns and sepias as the grains of deposited silver grow in size. They improved this method of obtaining tones by development by using thiocarbamide in addition to ammonium carbonate as a solvent for the silver halide ; greens, blues and violets can thereby be obtained. This method has been particularly studied by Mr. Dudley Johnston, the President of the Royal Photographic Society, and by investigating the effects of temperature, exposure, and variations in the developer he has brought the process to perfection. The slides now shown have been made by Mr. Dudley Johnston and kindly lent to me for demonstration purposes.

Recently, Messrs. Thorne Baker and Davidson of the Imperial Dry Plate Co. have also studied this method of obtaining direct colours on lantern plates, and some of the results obtained are shown in the next few slides, which have been kindly supplied by Mr. Thorne Baker. With a warm-tone lantern plate, as the exposure is increased and the time of development in caustic soda-quinol developer diminished, colours ranging from black through sepia, brown and red to deep orange are obtained. Using a metol-quinol developer and an ammonium carbonate bromide restrainer, colours are similarly obtained, not only with warm-tone lantern plates but also with gaslight lantern plates, the colours with the latter being especially brilliant.

Similar colours can be produced in the physical development of primarily fixed plates. For example, silver chloride-gelatin plates are exposed to give a weak visible image, fixed, and thoroughly washed. If developed with acid-metol silver, the precipitated silver is at first pure yellow and then changes through orange into red, reddish-violet, and finally blue.

As long ago as 1894 the Liesegangs gave a method of obtaining variously coloured prints on a silver chloride-gelatin paper.

They found that the longer the exposure and the diluter the hydroquinone developer, the yellower is the colour of the silver produced, as shown by the following table.

Tone of dry print.	Rel. Exposure.	Dilution of Developer.
Green black	1	1 : 5
Olive Green	2	1 : 5
Sepia	3	1 : 10
Brown	4	1 : 10
Red brown	6	1 : 20
Yellow brown	8	1 : 20
Red	5	1 : 30
Reddish	10	1 : 30
Yellow	20	1 : 40

These colours are really transmission colours, depending on the size of the silver particles, since the light is reflected from the white surface of the paper base.

The different colours obtained with the various printing-out papers before toning are similarly dependent on the size of the particles, this size being again dependent on that of the original grain of silver halide.

So far gelatin has been considered only as the medium in which the silver halide is dispersed, and the question has not been raised as to whether it is contained in the grains of the silver halide themselves. During the ripening of the emulsion the grain changes from an apparently amorphous condition to one which is definitely crystalline, that is, from a less stable to a more stable state, and one would, therefore, expect that it would be less sensitive to light. Actually it becomes more sensitive, and, at first sight, it would seem that the way out of the impasse is to assume that the grain really consists of some kind of combination of gelatin with silver halide, the effect of ripening being to alter this combination in such a way that the grain becomes more sensitive. This is not necessarily a valid assumption, however, since, as will be seen later, the sensitive spots on the ripened grains appear to be congregated on the surface, where conditions, owing to adsorption effects, may be quite different from those holding in the mass of the grain itself.

Eder has attempted to show that the grains contain gelatin by centrifuging them out from an emulsion after rapid washing with warm water; the separate grains were still found to contain about 2% of gelatin. This is no proof, however, that gelatin is contained in the grains; the gelatin remaining may be that which is adherent to the grains, since it is extremely difficult to remove adsorbed substances from a surface by mere washing.

If gelatin is present in the grain it is quite possible that as the emulsion dries the grains themselves will diminish in volume. Bellach after several days' drying, found a contraction in area of the grains varying from 0.57×10^{-5} to 0.67×10^{-5} sq. mm., but Hodgson and also Sheppard and Trivelli were not able to detect any difference in the dimensions of the grains in one and the same wet and dry emulsion. These observations are not necessarily contradictory, however, since the swelling or non-swelling may depend on the way in which the gelatin, if present, is distributed in the grain and on the resistance of the layers of silver halide to displacement.

The question has been attacked in another way by Reinders. If crystals of silver chloride, obtained by evaporation of an ammoniacal solution of the salt, are exposed to sunlight, they gradually become blue in colour, owing to the formation of silver, produced by photochemical decomposition, and its colloidal solution in the remaining silver chloride. The silver thus produced may amount to as much as 1% and is left behind as a residue when the chloride is dissolved in concentrated ammonia solution or in a solution of sodium thiosulphate. Silver chloride coloured in this way is known as photochloride; it may be produced artificially by allowing the crystals to form, in the dark, from an ammoniacal solution of silver chloride containing also colloidal silver, and the colours obtained may vary from yellow, through red, to reddish-violet and blue-violet, according to the colour of the silver sol used. The crystals so obtained are homogeneous in structure and colour; on exposure to diffuse daylight they gradually become indigo-blue, the colours of the lighter crystals going through yellow, red, red-violet, blue-violet and finally indigo-blue. The velocity with which the colour change takes place is always much faster than the production of colour from the colourless, pure silver chloride crystals. Moreover, with the latter the colour is confined to the surface, the interior being unchanged, whereas with the former the colour is uniform throughout the crystal. Now, when the crystals of silver chloride were produced from a solution containing gelatin, they also were found to be more photosensitive than the pure salt, and the blue colour produced on exposure was uniform throughout the crystal and not confined to the surface. It, therefore, follows that the gelatin was evenly distributed throughout the crystal, just as was the colloidal silver in the previous experiments. From a 2% gelatin solution the crystals contained 0.1% of gelatin but the influence of gelatin would be shown in crystals formed from a solution containing only 0.001% of gelatin, that is, one milligram of gelatin in 10 litres. It was further found that the addition of gelatin to the ammoniacal solution of silver chloride containing also colloidal silver, prevented the crystallising salt from taking up silver, that is, the adsorption of one colloid was prevented by another.

It is true that the above experiments of Reinders do not prove that gelatin is present in the silver halide grain of a photographic emulsion, but, reasoning by analogy, it seems safe to conclude that gelatin must be present, especially since the concentration of gelatin present during the emulsification is so much greater than in Reinders' experiments. Bancroft, from his study of the literature, comes to the conclusion that the grain contains both gelatin and water, and that there is a maximum sensitivity for a definite but small amount of both these constituents, the sensitivity decreasing when the proportions of these substances are greater or less than the optimum values. In support of his ideas he states the following: A silver bromide which contains no gelatin or extremely little is not so sensitive as a silver bromide containing gelatin. The photographic emulsion is also not especially sensitive if it is rich in gelatin, much speedier emulsions being obtained if the silver bromide is precipitated from a solution containing only a moderate amount of gelatin. Drying a photographic plate increases its sensitiveness up to a certain point and there must, therefore, be a limiting content of water for which the sensitivity is a maximum, everything else remaining the same.

Since gelatin is known to react with the halogens, especially with chlorine and bromine, Reinders's experiments would seem to indicate that it plays the part of a sensitiser in the photochemical decomposition of the silver halide. There has been much discussion about this, and Lüppo-Cramer claims to have proved that gelatin has no sensitising action, since he found that a collodion emulsion plate coated with gelatin did not give a print-out effect quicker than one not so coated. This experiment proves nothing, however, since any sensitising effect is not necessarily due to the gelatin surrounding the grain, but may be caused by the gelatin actually forming part of, or adsorbed firmly by, the grain. Schumann, on the other hand offers definite evidence that gelatin may act as a sensitiser. He covered one half of a glass plate with gelatin, leaving the other half bare ; the plate was then put in the bottom of a vessel in which silver bromide was produced by precipitation and gradually settled down. After deposition of the precipitate the plate was lifted out, carefully washed, dried, exposed to light, and then tested with a developer. There was found to be practically no change in the silver bromide which had been in contact with the bare glass, but there was an abundant formation of reduced silver in the silver bromide which had been in contact with the gelatin.

LA VIE INDUSTRIELLE EN FRANCE.

◆

LE CENTENAIRE DE L'INDUSTRIE DU GAZ EN FRANCE & LE CINQUANTENAIRE DE LA SOCIÉTÉ TECHNIQUE DE L'INDUSTRIE DU GAZ

La Société technique de l'Industrie du Gaz a fêté tout récemment le cinquantenaire de sa fondation, qui coïncide, sinon précisément avec le centenaire de l'invention du gaz d'éclairage, du moins avec celui de l'essor de cette industrie naissante, tant à Londres qu'à Paris

On peut discuter sur les mérites respectifs, comme inventeurs, de l'ingénieur français Philippe Lebon, de l'anglais William Murdoch, et du physicien hollandais Minckelers ; bornons-nous à dire que la mémoire de Philippe Lebon a été honorée, en France, par l'érection, déjà ancienne, d'une statue et, cette année, par la pose d'une plaque sur l'emplacement de la première usine à gaz française, construite en 1818 dans l'hôpital Saint-Louis, à Paris, pour les besoins de cet établissement.

D'autre part, la Société technique du Gaz a donné plus d'éclat à son Congrès annuel, en organisant une Exposition du Gaz qui s'est tenue au Jardin d'Acclimatation du Bois de Boulogne.

On y voyait les principaux types d'appareils à gaz modernes, soit industriels (fours), soit domestiques (fourneaux, radiateurs, chauffe-bains, becs à incandescence, etc)

Une remarquable section rétrospective montrait la série des becs usités depuis un siècle pour l'éclairage public, divers appareils historiques tels que celui de Dumas et Regnault pour la vérification du pouvoir éclairant du gaz par rapport à la lampe Carcel étalon, le brevet de 1799 et la brochure de propagande de Philippe Lebon, etc

Le Congrès a discuté de nombreuses communications, ayant trait notamment au débenzolage du gaz de ville, à son épuration, à la distribution du gaz dans Paris, au gaz des cokeries, et à beaucoup d'autres questions diverses

Enfin, une "Semaine gazière" réservée au personnel des Sociétés gazières, comportait des conférences d'ordre technique et pratique, et des visites d'usines ; elle a été également très suivie, et cet ensemble de manifestations a montré que l'industrie gazière, malgré la concurrence de l'électricité, a encore devant elle un champ immense d'applications

LE NOUVEL ÉTABLISSEMENT BALNÉAIRE DE LA VILLE DE PARIS, À LA BUTTE AUX CAILLES

La Ville de Paris, qui ne possédait pas jusqu'ici de piscine vraiment moderne, en possède aujourd'hui deux qui peuvent rivaliser avec les mieux aménagées des grandes villes d'autres pays : l'une, à ciel ouvert, et de grandes dimensions, est destinée spécialement aux épreuves sportives (piscine des Tourelles) ; l'autre, établissement balnéaire complet avec piscine couverte et bains-douches en cabines, est destinée principalement aux besoins de la population ; toutefois, des tribunes sont installées au-dessus de la piscine pour permettre aussi des épreuves publiques de natation.

Nous ne parlerons ici que de ce dernier établissement, situé dans le quartier de la Butte aux Cailles, près de la place d'Italie. Sa charpente en arcs de béton armé donne au grand hall de la piscine un aspect très satisfaisant ; la piscine, de 33 x 12 m. (108 x 39½ feet), avec profondeur variable de 0m75 (2½ft.) à 3m (10ft.), est également une vaste cuve en béton armé portée par des piliers de même nature, de sorte qu'on peut accéder au-dessous du fond et contrôler son étanchéité.

Une autre particularité remarquable de l'établissement, c'est qu'il est alimenté directement par l'eau à 28° centigrades du puits artésien de la Butte aux Cailles, situé tout près de là, et qui débite 72 mètres cubes (15,840 gallons) par heure, de sorte qu'on peut, sans réchauffage, entretenir la piscine en eau presque courante, par conséquent toujours propre. Du reste, on dispose aussi de l'eau de source du réseau municipal, que des chaudières permettent de réchauffer selon les besoins. Les mêmes chaudières servent pour les bains-douches annexés à la piscine, et pour le chauffage de l'air des halls et salles de déshabillage.

Ce bel édifice, agencé de la façon la plus moderne, a coûté environ 4 millions de francs

PIANO ÉLECTRIQUE, SYSTÈME MARTIN & MAITRE.

On reproche souvent au piano le caractère fugitif et presque saccadé des sons émis par les cordes vibrantes sous le choc du marteau, bien inférieurs aux sonorités persistantes du violon ou de l'orgue, que l'exécutant prolonge à son gré, ou relie entre eux sans aucune interruption

Sans doute, les virtuoses du piano, par la perfection de leur jeu, atténuent cette infériorité inhérente à la nature même de l'instrument, mais il n'en serait pas moins très désirable, pour la grande majorité des pianistes, de disposer d'un instrument plus souple, plus nuancé, sans renoncer pour cela aux avantages d'articulation nette que permet la technique de la corde frappée par un marteau

Après de longs essais, deux inventeurs de Rouen, M.M. Martin & Maitre, ont trouvé une solution ingénieuse à ce problème difficile. Leur piano électrique, dit "Pianor," comporte, juste devant chaque corde en acier, un petit électro qui, par l'envoi ou la rupture du courant, la fait vibrer comme sous le choc du marteau, avec un son plus pur. Si le pianiste continue à appuyer sur la touche, la corde elle-même, par l'intermédiaire d'un petit mécanisme commandé par un diapason, entretient indéfiniment son mouvement vibratoire, et la note se prolonge ainsi, aussi longtemps qu'il convient à l'exécutant

Du reste, les marteaux du piano ordinaire ne sont pas supprimés dans le nouvel instrument, de sorte qu'on peut à volonté : jouer à la façon ordinaire, avec les marteaux seulement ; obtenir un effet d'orgue, en jouant avec le système électrique, sans que les marteaux frappent les cordes ; combiner les deux effets, en plaquant les accords avec les marteaux, et en filant le chant en sons continus analogues à la flûte ou au hautbois.

Ce remarquable instrument, susceptible de donner un grand charme à l'exécution des morceaux d'orchestre dont la réduction pour piano est généralement sèche et trahit les richesses de l'œuvre originale, peut aussi, par un effet inverse, rendre de grands services aux compositeurs, qui, au piano, ne peuvent se rendre un compte exact des effets d' orchestration qu'ils ont médités.

NOTES ON BOOKS.

TIME MEASUREMENT: an Introduction to the Means and Ways of reckoning Physical and Civil Time. By L. Bolton. London: G. Bell and Sons, Ltd. 6s. net.

In the compass of 166 pages, Mr. Bolton gives us an accurate and concise account of timepieces in which matter or stuff moves, from the water clock of the Greeks and Romans (Clepshydra) and its near kin the sand-clock, the lamp clock and

the oil clock, to the modern chronometer and the instruments in the chronograph room at the National Physical Laboratory: essential or characteristic mechanical features being well illustrated and described. In the preface our author pays tribute to the merits of such clocks as have come down to us from Plantagenet times and pleads for the judging of such clocks rather by their works (movements) than by the dials and externals.

As regards the word *cloche* (French) and *cloch* (Welsh) parallels with our *clock*, we are reminded (p. 52) of the tradition that some of the early clocks had no means of indicating but the sound of the bell. This tradition appears to be somewhat confirmed by Vitruvius in the tenth book of his *De Architectura*, where he describes as old (*a majoribus traditam*) a device by which each mile of the distance travelled by a land-car (rheda), or by a ship, can be indicated by sound to the ear when a ball falls into a brazen vase (or bell), and the total being visible at any time by counting the balls in the bell. The balls are placed, each in one of a number of perforations which are equally spaced in the rim of a horizontal wheel, and when a ball comes over a gutter in the underplate it rolls down and falls into the bell. With suitably timed driving this device may obviously indicate hours, and in either case the set to zero would by returning the balls to the holes in the rim of the horizontal wheel. Thus we have the germ of a "clock" movement in the sense of bell indication which was suggested or perhaps constructed and used about 2,000 years ago. In relation to the car, Vitruvius mentions a gearing down of 400 from a road wheel of four feet diameter as appropriate for indicating the Roman mile of 1,000 complete or 5ft. paces. Versions of Vitruvius differ somewhat, but all the above details are, we believe, common to most or all. Our immediate source is the stereotyped small octavo text of Tauchnitz dated 1838, pp. 229-231. This matter is in the tenth book, chapter IX. (called Chapter XIV. in some versions).

Time-pieces in which no material, but only a shadow moves, are considered with corresponding thoroughness, and we may refer to the plate opposite p. 48, showing a group of sundials; also the improvised clinometer represented on p. 49, as giving a ready means of extemporising sundials if used in accordance with the lessons taught by the armillary sphere, Fig. 2, p. 29. The meridian dial, Fig. 12, p. 50, is interesting as serving to indicate noon only, as is the case with the dipleidoscope of Dent, but this latter, when properly set, gives an indication which is exact to the fraction of a second. Either instrument may be provided with an addition by which the actual reading gives mean noon as distinguished from apparent noon. In the case of the meridian dial the addition is a graph of the equation of time; this graph being shown by Fig. 12. A good illustrated account of Dent's dipleidoscope is to be found in "Cassell's Illustrated Exhibitor, 1851 and 1852," pp. 530-531.

General data as to the various aspects of astronomical time, the various kinds of "day," also the distinction between the real sun and the mean sun are given much in the sense of the statements in the Nautical Almanac, but in language better suited to the general reader, and with diagrammatic aid where desirable.

VANADIUM ORES. By Members of the Scientific and Technical Staff of the Imperial Institute. With a map. London: John Murray. 5s. net.

The only fault which we can find with this recent addition to the Imperial Institute's series on Metallurgic Geography with special reference to the British Empire, is that the short title does not do justice to the thorough and masterly way in which the more essential elements of collateral information are introduced.

About a page on the discovery and properties of vanadium, emphasises the sources of liability to mistake in recognition and in respect to reduction: also cites five representative vanadium compounds and indicates such trends of affinity as may lead to subversive results in actual practice. This exceptionally thorough example of concise but suggestive technical writing will not only serve to introduce vanadium to the beginner, but will also remind the most experienced chemical worker of the danger points in relation to observation, research and practice.

Another page gives a preliminary note as to vanadium ores with clear indications as to composition, and where necessary, companionship and locality; but this account is not burdened by formulæ.

Then, on page 3 under the heading "Occurrences of Vanadium," the close systematic body of the book commences with quantitative study of vanadium in the earth's crust and the conditions influencing localisation: also how localisation and companionship may have determined the nature of the ore. The metallurgy of vanadium (pp 7-10) is introduced by a more elaborate study of the chief ores with chemical formulæ, followed by a concise but sufficient account of the leading or typical methods of reduction.

Under "Uses of Vanadium," there is brief mention of use as a catalyst, dyeing and mordanting, marking ink, decorating pottery, photography and medicine; the chief use, however, is in the formation of alloys, as with steel, copper or aluminium, the usual effect being to toughen the metal and give it an increased power of resisting repeated shocks, one of vanadium in four hundred of steel giving much about the same result as a greater quantity.

Detailed study of the world's production of Vanadium ores, from the geographical, industrial and financial aspects concludes with a world map (pp. 13-65), after which a bibliography of seven pages completes this book, which may not only be regarded as a concise introduction to the subject of vanadium but also as a useful lesson to any one intending to write a practical text-book on industrial chemistry.

COBB LECTURES.

CERTAIN FUNDAMENTAL PROBLEMS IN PHOTOGRAPHY.

By T. Slater Price, O.B.E., D.Sc., F.I.C., F.R.S.

(Director of Research to the British Photographic Research Association).

Lecture III.—*Delivered April 7th,* 1924.

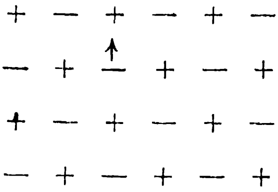
The preceding discussion of the effect of gelatin on the photosensitivity of the silver halide grain leads naturally to the questions of the visible and latent images. Dealing first with the visible image, there is no doubt that when the silver halides are exposed to the light halogen is set free ; this has been proved experimentally, and is confirmed by the fact that the darkening, which accompanies the fission of the halogen, is accelerated in the presence of compounds which absorb halogen and, therefore, act as sensitisers. Thus, printing-out papers contain, in addition to the silver halide, silver nitrate or the silver salt of an organic acid, especially citric acid, which acts as a sensitiser. Doubt comes in however, as soon as the nature of the dark product formed on exposure, the photohalide, is considered. According to some investigators, of whom Carey-Lea was notably the pioneer, the photohalide is a sub-halide, Ag_2X, where $X = Cl$, Br or I, or a "lake-like" combination of the sub-halide with the normal halide in varying proportions, and in favour of this it is stated that a sub-fluoride of silver, Ag_2F, has been isolated by Guntz. All attempts to prepare corresponding sub-salts containing the other halogens have not met with success, however, and doubt has even been expressed as to the unitary character of the so-called sub-fluoride. At one time Luther put forward what was considered to be definite evidence based on potentiometric measurements, but succeeding investigators have not been able to confirm his results. The alternative explanation of the nature of the photo-halides is that they consist of colloidal solutions of silver in excess of silver halide. In favour of this are the experiments of Reinders, already quoted, and also those of other investigators. Thus it was found by Lüppo-Cramer that if a silver sol is added to a sol of silver halide and the mixed sols then precipitated with sulphuric acid, a coloured product identical in its properties with the photohalide is obtained. Lüppo-Cramer has adduced considerable further evidence, but it should be mentioned that, as a result of his experiments on the preparation of various "soluble," allotropic modifications of silver, Carey Lea first suggested that silver in the photo-halides was present as allotropic silver.

The usual explanation given of the sensitising action of silver nitrate with respect to the visible image is that it removes the bromine set free by the action of light, in accordance with the equation :—

$$Br_2 + AgNO_3 + H_2O = AgBr + HOBr + HNO_3.$$

The matter is, however, by no means as simple as is represented by the above equation, since adsorption effects undoubtedly play a part. It has been proved experimentally that when silver bromide is precipitated from a solution containing excess of silver nitrate, some of the excess silver ions are adsorbed on the surface of the precipitate and cannot be removed by washing. Similarly, if the precipitation takes place in the presence of excess of potassium bromide, bromide ions are adsorbed. If the concentrations used are such that the silver bromide is obtained as a sol, the particles are positively charged when the silver nitrate is in excess, and negatively when the bromide is in excess, as would be expected from the electrical charge on the adsorbed ions. The two kinds of silver bromide may be spoken of as "silver-body" (Ag-body) and "bromide-body" (Br-body) respectively.

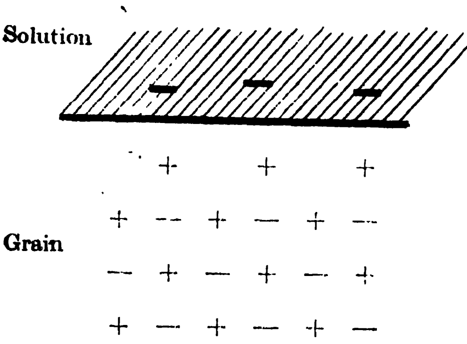
The question naturally occurs as to whether these adsorbed ions play any part in the photosensitivity of the silver bromide. To answer this, it is necessary to refer to modern work on crystal structure. It has been shown that even apparently amorphous silver bromide has a lattice structure such that each silver atom is surrounded by six bromine atoms, and each bromine atom in its turn by six silver atoms. Owing to electron interchanges the silver atoms are positively charged and, therefore, may be termed silver ions; similarly the bromide is present as bromide ions. A section through the crystal may, therefore, be represented as follows, the +'s representing the silver ions and —'s the bromide ions.



I

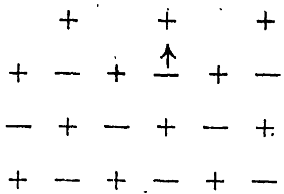
Assuming that the action of light is electrical in its nature, the process which takes place on exposure may be represented as the transfer of an electron from a Br-ion to a Ag-ion as shown by the arrow, with the formation of neutral atoms of bromine and silver.

The Ag-body must be represented as having silver ions attached to its surface as in diagram 2, the points of attachment being the oppositely charged Br-ions.



2

The negative ions represented as in the solution are the NO_3-ions from the silver nitrate. Various considerations based on the extent of the hydration of ions, and which need not be entered into here, show that the electrostatic action of the NO_3-ions may be neglected, so that 2 simplifies to 3.



3

Compared with pure silver bromide, 1, the surface of 3 is so altered that the photochemical processes will be affected. Consider in 1 and 3 the transfer of an electron from the Br-ion to the Ag-ion, as represented by the arrow. Assuming all other things to be equal, in 1 the negative Br-ions on either side of the Ag-ion will have a repelling effect on the transfer of the electron, both in its initial and final positions. The repelling effect will be greatest in the final position, since the Br-ions on either side of the Ag are then nearer to it than they are to the Br-ions in the layer underneath. Compared with 3, therefore, it will be more difficult for the transfer of an electron to take place, that is, the Ag-body, 3, should be more sensitive to light than the pure substance 1, in the sense that its spectral sensitivity should be extended towards the red.

The above considerations are due to Fajans and his co-workers, especially Frankenburger, and have been tested experimentally. It was first shown that in the presence of silver nitrate a sufficient density of Ag-ions covers the surface of the silver bromide for the surface itself to be considered changed. By exposure to light of various wave lengths, obtained by the use of appropriate filters, it was found that pure silver bromide, which had been dried in a cathode-light vacuum at 300°-350°, visibly darkened in an inert atmosphere between 410 and 435μμ, but was unaffected by longer wave lengths. In the case of the Ag-body, however, darkening took place over all wave lengths between 400 and 620μμ. The Ag-body was made by precipitating 25 cc. of N/5 silver nitrate with 20 cc. of N/5 potassium bromide, the excess of silver nitrate acting as an acceptor for the bromine liberated by the action of light. The Br-body, which can be represented similarly to 3, using, however, —'s in place of +'s for the adsorbed ions, was made similarly to the Ag-body, using an excess of potassium bromide. It behaved similarly to, and had the same threshold value as pure silver bromide, namely 410-435 μμ. In the case of both the Ag- and the Br-bodies it was proved analytically that bromine is set free by the action of light.

The most interesting results were obtained when the well-washed Br-body was exposed under alkaline solutions (sodium hydroxide, sodium carbonate, or ammonium hydroxide). It was then found to be sensitive over the same range as the Ag-body, that is, between the wave lengths 400 and 620 μμ. The most important fact, however, was that when photochemically decomposed there was no liberation of bromine. It follows, therefore, that the increased sensitivity must be due to the decomposition by light of a substance analogous to silver hydroxide, and not of silver bromide, that is, that adsorbed Br-ions in the Br-body had been replaced by OH-ions, forming an hydroxide-body (OH-body). Such adsorption replacement is a well-known phenomenon. In agreement with this it was shown that pure silver oxide is sensitive over the same region of the spectrum as is the Br-body under alkaline media. The transfer of an electron from from OH-ion to Ag-ion thus seems to take place more readily than the corresponding transfer from Br-ion.

Another important result concerned the sensitising action of silver nuclei. The Br-body, and also pure silver bromide, which were sensitive to wave lengths of 435 μμ and less, but not to longer wave lengths, became sensitive under a filter transmitting 560-720 μμ after previous exposure under a filter transmitting 410-510 μμ. Silver nuclei are formed in the first exposure and these have a sensitising or accelerating action in the second exposure. This sensitising action can be accounted for by an extension of the theory given previously. The results agree with the known fact that colloidal silver acts as a panchromatic sensitiser of the photographic plate. Eder has shown that after a short exposure the silver halides are more sensitive to long wave lengths than before, and Carey Lea and Lüppo-Cramer have demonstrated that the synthetic photohalides also show a similar spectral sensitivity.

The OH-body seems to be most important, since minimal quantities of substances which react alkaline can produce the effect. Washed Br-body, when boiled for a long time under water in the light of a photographic dark room, becomes discoloured, probably because alkali is dissolved from the glass of the containing vessel; OH-body is thus formed, and this is sensitive to the light of the dark room. With tap water in place of twice-distilled water, darkening takes place in a comparatively short time, because of the basicity of the carbonate-containing water. Now since OH-ions so readily replace adsorbed Br-ions, it is probable that the latter will also readily be replaced by the anions of organic acids and dyes which give soluble silver salts, and it is possible that this adsorption replacement accounts for a number of sensitising effects, the transfer of an electron to the Ag-ion being thereby facilitated. In support of this idea it may be mentioned that Weigert has shown that in silver halide emulsions containing organic silver salts in addition, the photochemical process consists in the decomposition of these salts, which are thus more sensitive than the silver halides. This recognition of the influence of adsorption and adsorption-replacement reactions will probably play a great part in the advances made in photography in the future. Mees, Sheppard, Bancroft and others have considered the question of adsorption in the past, but not in the definite manner due to Fajans.

As compared with the visible image the difficulties are very much enhanced when the latent image is considered, since further complications arise owing to the fact that the presence of a latent image is only made known by the process of development. The amount of concrete and definite evidence is not large, and the opinions held are so varied, that it will be sufficient to deal with the subject somewhat briefly. Broadly speaking, there has been a division of opinion as to whether the formation of the latent image involves a physical change only in the silver halide, or a chemical change. Of physical theories there have been several. Some of them have been exactly opposite in character, Namias, for example, assuming that the silver halide grain is polymerised by the action of light, whereas Hurter and Driffield assumed depolymerisation of a complex molecule. Other physical theories were those which assumed mechanical disintegration of the grain (Bredig), the formation of a labile modification (Chapman Jones), or that the grain was thrown into a state of molecular strain (Bose). As pointed out by Bancroft, however, all these physical theories seem to be put out of court by the fact that the action of light can be duplicated by immersing the plate in a solution of a weak reducing agent; such as stannous chloride or sodium arsenite, after such immersion the plate can be developed by means of an ordinary developer.

There have been two chief chemical theories. The one assumes the formation of a sub-halide of silver, which is then readily acted on by the developer, but, as already pointed out, no definite evidence has been adduced for the existence of such sub-halides, except silver sub-fluoride. The other theory supposes that the latent image consists of silver, set free by photochemical action, which silver then acts as a nucleus in development. At first it was thought to be free metallic silver, but this did not agree with the great resistance of the latent image to nitric acid, for example, so that the theory was later modified by Abegg by supposing that the silver is present as colloidal silver which is adsorbed by the silver halide. This idea has been especially developed by Lüppo-Cramer, and it has been shown that synthetic adsorption compounds of colloidal silver and the silver halides behave towards chemical reagents very similarly to the latent image and the photohalides. The facts of physical development support the idea that silver is present in the latent image.

A modification of this idea is based on the fact that the sensitivity of high speed emulsions can be more or less destroyed by the use of certain oxidising agents before exposure. It is supposed that during the preparation of the emulsion incipient reduction of the silver halide by the gelatin takes place, and that the traces of colloidal silver so formed act as a catalyst for photochemical decomposition; such catalysis is supported by the experiments of Fajans. Renwick has suggested that these traces of colloidal silver are in such a state that they cannot act as nuclei in development; the action of the light is to bring about their coagulation to such a coarse condition that the aggregates so formed can act as nuclei. Although there is evidence that light will coagulate suspensoid sols, it is somewhat difficult to postulate coagulation in a medium such as that of the silver halide grain.

In referring to the chemical theories nothing was said as to the mechanism of the action whereby the silver is set free by the light. The chief argument brought against a chemical theory has been that the incident energy necessary to make a photographic plate developable is insufficient to produce any appreciable decomposition. This argument may be valid if a straight decomposition of the silver halide is considered, but it probably does not hold if applied to the transfer of electrons when influenced by adsorbed material in some such way as that postulated by Fajans.

If it be conceded that the latent image does consist of silver in some form or other, the question still remains to be answered as to what constitutes the sensitivity of the photographic grain, since it is this sensitivity which gives rise to the formation of the latent image on exposure. The first point to be considered is this: when a plate is exposed and developed under ordinary conditions, an image is formed because there is more blackening, that is, a greater density, in some places than in others, or, in other words, the amount of silver deposited varies in different parts of the plate, according to the exposure. Is this variation in the amount of silver due to every exposed grain having become developable, but only a definite fraction of the grain being reduced to silver on development, the fraction being all the greater the greater the exposure, or does only a certain percentage of the grains, depending on the exposure, become developable, each developable grain being reduced completely to silver, but not communicating its developability to contiguous grains? This question can only be answered by experiment, and the accompanying Fig. 16, which depicts developed grains (black) in contact with undeveloped

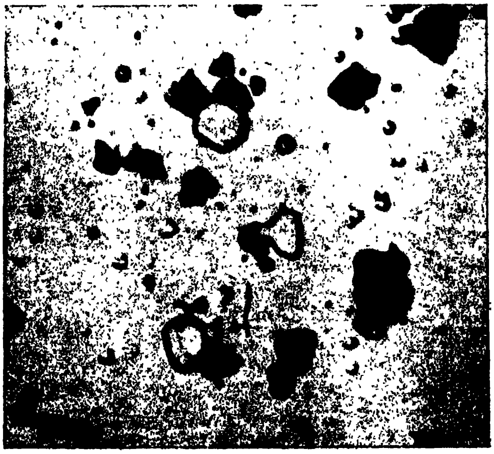


Fig. 16.

grains, shows that it is the latter process which occurs. However, it should be mentioned that in some emulsions clumps of grains occur, and Sheppard and his co-workers maintain that when one grain in the clump becomes developable the whole clump develops.

It follows from the above that the individual grain is the fundamental unit, and the question immediately arises as to why, on exposure, a change occurs in different grains at different times. The answer might be that in a photographic plate there is not a single layer of grains, but many layers; the upper layers act as a screen to the lower ones and the extent of penetration of light will then depend on the exposure. Prof. Svedberg, of Upsala, found, however, that when a plate contained such a thin coating that there was only a single layer of grains, all the grains were still not changed simultaneously. He then suggested that the difference in behaviour might be due to variation in size of the grains, but further experiments proved that this suggestion was not correct. Independently, and at about the same time, Slade and Higson, of the British Photographic Research Association, came to the same conclusion, and since then Dr. Toy, of the same Research Association, has investigated grains which, in shape and size were as nearly identical as possible, and proved conclusively that some required roughly two hundred times as much light energy, incident on unit area of the plate, as others, in order to make them developable.

Further investigation has shown that on each grain there seem to be certain "centres" from which development starts. Chapman Jones, in 1911, showed that by stopping development almost immediately after it was started, particles of silver had been formed in the grain; these could not be observed microscopically until they had been enlarged to visible dimensions by deposition on them of mercury. In 1917, Hodgson, in America, showed that by stopping the development at a somewhat later stage, silver could be observed at certain points only in the grain. Then Svedberg, in 1922, working along similar lines and using an emulsion with spherical grains, proved conclusively, in a very ingenious manner, that these centres occur on the surface of the grain. Further evidence of this has been obtained by Toy, using emulsions in which the grains were flat plates; as shown in the diagram, (Fig. 17), the centres occur mostly at the edges of the plates, as would be the case if they were on the surface.

It might, of course, be said that the occurrence of these centres on the surface is simply a development phenomenon, due to the greater solution pressure which occurs at irregularities of the surface, and especially at the edges of crystals. This objection has been raised by Mees, and has been considered by Toy, who has shown conclusively that the phenomenon in question does not play a part. Moreover, it would be absurd to assume that the change due to exposure is localised in the grain and yet that the local action of the developer was not at the points where

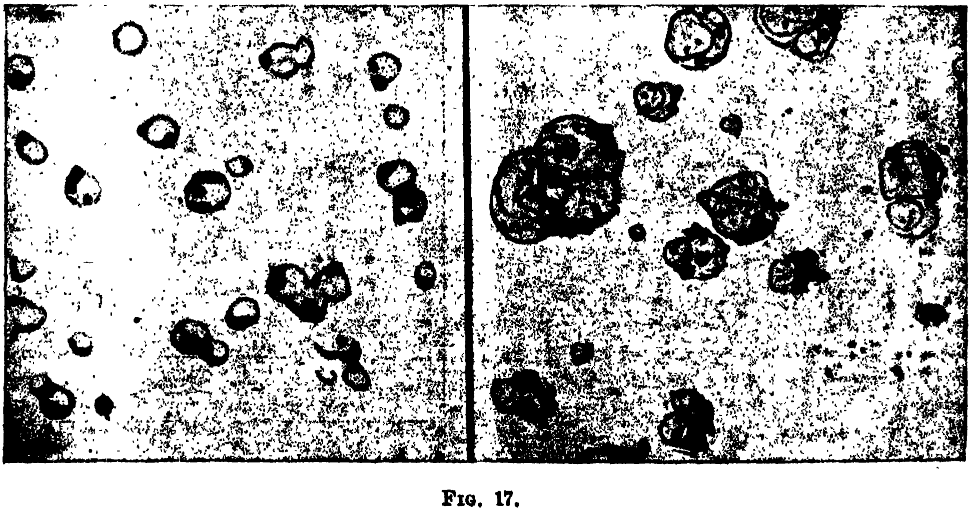

FIG. 17.

the change had taken place, for if this were so there is no reason why exposed grains should act differently from unexposed grains. Again, the number of centres increases with the exposure and it is difficult to avoid the conclusion that their localisation agrees with that of the sensitive material which is the precursor of the latent image.

Painstaking and exacting measurements by both Svedberg and Toy have shown that these centres are distributed among the grains entirely haphazard, according to the law of chance. This law states that the chance (P_r) of the distribution of N centres between a grains resulting in any one grain having r centres is

$$P_r = (N/a)^r e^{-N/a} / r!$$

and this equation has been found to correspond with the results obtained by direct counting of the centres.

Different views are held at present as to how these centres are formed, and Toy has summarised them as follows :—

(1). The centres are formed in homogeneous grains entirely by light which is incident at points on the plate in finite discrete quantities.

(2). The centres are pre-existent in the grains before exposure as a chemically different substance, the function of the light being to change their condition in such a way that they become capable of acting as reaction centres. The light is considered as acting equally on all grains.

(3). A combination of (1) and (2), that is, heterogeneous radiation is incident on grains containing specially light-sensitive points.

These various views may be considered separately.

(1). This view has been developed by Silberstein, of the Kodak laboratories, and investigated experimentally by other workers there. Mees states the matter simply, as follows :—" If we had no prior knowledge of the wave theory of light, it is clear that the simplest explanation of the sensitiveness of different grains would be that, instead of a continuous flow of light in the form of waves on to a sensitive plate, the light was falling upon it as a rain of projectiles and that these projectiles made developable any grains that they hit, the grains that they missed not being developable but being hit later if they continued to be exposed to the radiation. Naturally, the bigger the grains the more likely they are to be hit, so that a calculation, based on the probability theory, can be made of the relation between the size and the percentage number of grains which will become developable after a given exposure." Silberstein suggested that these projectiles are discrete light quanta and called them " light darts ", each one being imagined to consist of a long train of waves of very small diameter travelling with the velocity of light.

In the above assumptions there is nothing relative to the occurrence of centres in the grains. The only postulates are the " light darts ", the area, or rather the projected area of the grains, and a haphazard hitting of this area by the light darts. From these postulates Silberstein developed the equation

$$k/N = 1 - e^{-na}$$

where a is the projected area of the grain, k the number of grains hit, N the total number of grains per unit area, and n the number of light quanta impinging on unit area. This equation indicates that the chance of a grain becoming developable increases very much with the size, a result which had been previously obtained by Svedberg.

Trivelli and Righter have submitted this equation to the test of experiment and claim to have verified it. Unfortunately the test was not made on single grains, but on clumps of grains, the number of grains varying in the different clumps and hence the projected area varying. For the particular emulsion used it was proved that each clump acts as a single grain as far as developability is concerned. The reason for using clumps was that thereby a much bigger variation in the area could be obtained. The results of three of their experiments are shown in (Fig. 18) by the

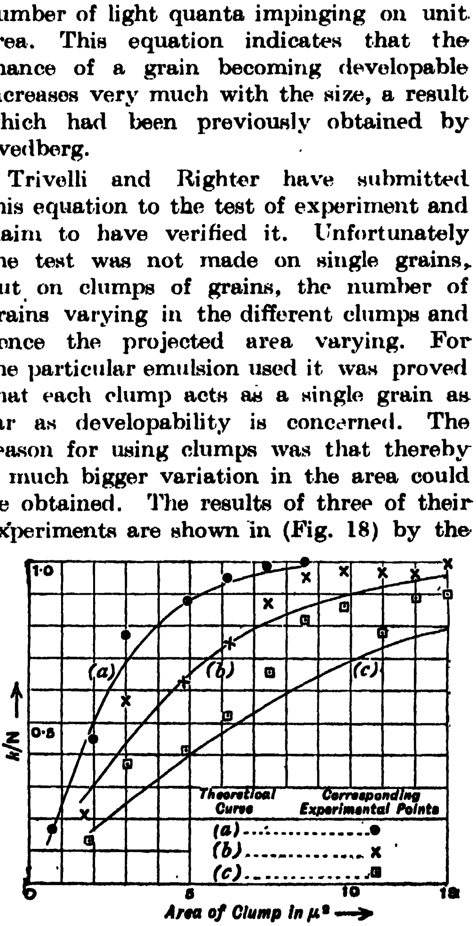

Fig. 18.

marked points, the theoretical curves being the continuous lines. It will be seen that only in one case is the agreement fairly good. There is certainly room for doubt whether these experiments really support the theory. Toy has tested the equation for sets of equal-sized grains and found that it breaks down completely.

If it were true that the grains were really subjected to bombardment by discrete light darts, the centres already mentioned would represent their points of impact. In that case, however, the centres would be distributed, on the average, equally over the projected area of spherical grains and not equally over the surface, and in the case of flat plates the distribution would be equal over the surface and not concentrated at the edges. The actual topographical distribution of the centres has already been mentioned ; it is not in accordance with the demands of the light dart theory as given in (1).

(3). It will be convenient to deal with (3) before (2).

Work carried out by Leimbach, and the results of some preliminary experiments done in the Kodak laboratories, indicate that for high speed emulsions several hundred quanta of light are necessary per grain in order to make the grain developable. This would make a simple light dart hypothesis insufficient, and consequently (quoting Mees) "we are thrown back on the idea of differential sensitiveness among the grains, or of spots of limited area on the grains, so that of the hundreds of quanta striking a grain only one may be considered to be operative, the rest falling upon the insensitive portion of the grain." This modification of the original thesis thus admits the possibility of heterogeneity in the grain and, therefore, of "centres." Its mathematical consequences, in conjunction with the idea of "light darts", have been worked out by Silberstein. A crucial test, however, may be applied as follows :—A plate is exposed to a beam of monochromatic blue light for a given time and the percentage of grains changed, that is, made developable is ascertained. A similar experiment is done with a beam of monochromatic violet light, using the same intensity, as measured by the thermopile, and the same time of exposure. Since the frequency of violet light is greater than that of blue, the number of quanta received by the plate for equal times of exposure and equal incident intensity will be more for the blue than for the violet ; that is, under proper conditions blue light should cause a greater percentage of grains to be changed than will violet light. Toy has shown, however, that the opposite is the case, so that the assumption of light darts does not predict results which are in accordance with experiment. Thus, at present, both (3) and (1) seem to be ruled out of court.

(2) has now to be considered. Is there any chemical evidence for an heterogeneity of the grain which would indicate the presence of sensitive spots which are pre-existent to light action?

It has already been mentioned that a solution of sodium arsenite acts on the plate in a way similar to light, that is, it makes it developable. Clark, working in the laboratories of the British Photographical Research Association, has shown that when a plate which has been immersed in this solution for a suitable time is partially developed, the centres from which development starts are not only distributed amongst the grains according to the same law of chance as holds when the exposure is to light, but that they have exactly the same topographical distribution, that is, both the light and the sodium arsenite appear to act on the same points in the grains. Further chemical investigation indicated that the substance forming the centres could not be silver bromide. Now if the sensitivity of the grains is chiefly due to this substance, it follows that if it is removed the sensitivity will be reduced to that of pure silver bromide. Naturally this can be best tested on high speed emulsions, and to apply the test, Clark made use of the well-known fact that the latent image, that is, the product of light action, can be removed by chromic acid. Two pieces, A and B, of a highly sensitive plate were taken. A was exposed to an intensity such that, if developed, all the grains would be changed, that is, all the specially sensitive points would be affected. A and B were then placed together in a solution of chromic acid, without developing A. After being thoroughly washed and dried A and B were exposed together in the ordinary sensitometric apparatus used for measuring the sensitivities of plates, and it was found that B was always more sensitive than A. The plate sensitiveness was not reduced to zero, but to the same constant value for all plates, which probably corresponds with that of the silver halide itself. Two examples of the results obtained are given below.

1. (*a*) Sensitiveness of the untreated plate =215
   (*b*) Sensitiveness after treatment with N/20 chromic acid for 7 minutes = 68
   (*c*) Sensitiveness after treatment with N/20 chromic acid for 7 minutes after a preliminary exposure of 8 seconds =5.
2. Using N/50 chromic acid instead of N/20, the respective sensitivities were: (*a*) = 215, (*b*) = 105, (*c*) = 5.

It is known that the sensitiveness of a plate is reduced by merely bathing it in chromic acid without preliminary exposure, but even bathing it for one hour will not reduce it to the low value obtained in the above experiments after a preliminary exposure. This is illustrated in (Fig. 19).

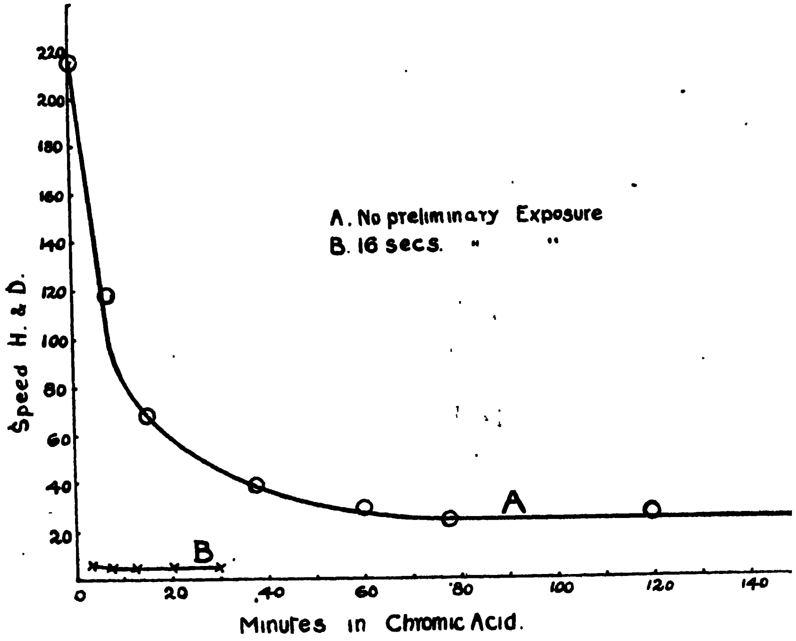

Fig. 19

Increase in the preliminary exposure, past a certain minimum value, for a given time of immersion in chromic acid, does not bring about a corresponding decrease in sensitivity.

Similarly Clark has found that treatment with chromic acid solution readily and completely removes the "latent image" formed by the action of sodium arsenite, whereas the sensitivity to sodium arsenite is only slowly reduced by immersion in chromic acid. It follows that the product of the action of light (and of fogging agents) on the plate is much more readily attacked by chromic acid than is the sensitivity-giving material itself, although this latter is slowly attacked.

From the above there seems to be no doubt about the validity of (2), that is, that the extreme light sensitiveness of the silver halide of the photographic emulsion is primarily due to the presence of minute traces of some other substance. The question has still to be answered as to what this substance is. Clark has endeavoured to find an answer by the application of the results of Fajans' work to a consideration of the fogging action of hydrogen peroxide and ozone. On the assumption that the sensitive substance consists of OH-body he was able to give a better general explanation than has previously been put forward of the apparently very contradictory observations made in this connexion. Fajans and Frankenburger showed, as already stated, that the OH-body behaves in such a way that it seems as if an electron is readily transferred from the OH-ion to the Ag-ion, with the formation of silver nuclei, that is, the hydroxide body behaves as if it were silver hydroxide. Now it is well known that silver oxide readily reacts with hydrogen peroxide and ozone, giving silver, and presumably silver hydroxide would act in the same way. Thus the action of the peroxide on the plate would give silver nuclei which would act as development centres and give rise to fogging.

The explanation of sensitivity cannot, however, be as simple as this, since the phenomena observed are very various and extremely complicated. For example one is immediately met by difficulties when an attempt is made to apply the hydroxide body theory to Clark's results with chromic acid. It would be expected that the OH-body would be destroyed more readily by the chromic acid than the silver nuclei formed from it on exposure, whereas the opposite is the case. At present, however, our exact knowledge of the effect of adsorption on chemical reactions is so limited that it is not necessary further to discuss the matter.

So far mention has only been made of sensitive centres on the surface of the grain. In addition to these, however, there seem to be internal nuclei present in the grain. The evidence for this is given by Lüppo-Cramer's work on "Keimblosslegung" or "nucleus exposure", which may be illustrated briefly as follows. The surface latent image on two equally-exposed lantern plates was removed by treatment with a chromic-sulphuric acid mixture (cf. Clark's experiments); after washing out thoroughly the chromic acid, one of the two plates was bathed for 30 seconds in a one per cent. solution of potassium iodide and then developed in the same physical developer as the other. The plate treated with iodide showed, after three minutes, the whole of the scale in a Chapman Jones sensitometer, whilst the control plate gave no image after 30 minutes. An explanation of this is that when the silver bromide grain is transformed into the iodide it is broken up into a number of finer particles—this has been confirmed by Renwick and by Sheppard, Wightman and Trivelli—and that thereby internal nuclei of silver are laid bare and initiate the process of development. Lüppo-Cramer, in his book on "Kolloidchemie und Photographie" gives an explanation to the effect that the adsorption compound of silver with silver iodide is less stable than that with silver bromide, and that therefore the nuclei are rendered more active. This is in accordance with the known stabilities of the photohalides, whereas with silver ions the adsorption increases in the series $AgCl \rightarrow AgBr \rightarrow AgI$. Whatever the explanation may be, by transformation into iodide the grain is apparently opened up in such a way that nuclei are laid bare to the action of the developer.

These experiments show that after exposure to light there are present internal nuclei from which, after being laid bare, development can proceed. They do not show whether the nuclei, or sensitive centres from which the nuclei are formed on exposure, are pre-existent in the unexposed grain. Some recent experiments of Sheppard, Wightman and Trivelli contribute something towards the solution of this problem. Single layer plates were treated with various reagents, washed, dried, exposed and chemically developed. When the pre-treatment was with potassium iodide, or with chromic acid followed by potassium iodide, the sensitivity was reduced to about 1/512th, part of the original value; treatment with chromic acid alone to remove the surface sensitivity, gave a reduction to about the 1/32nd part of the original speed. When, however, the treatment was with chromic acid, then with potassium iodide, and again with chromic acid, the sensitivity was destroyed to such an extent that 16,000 times the normal exposure would not give a developable image. Thus, opening up the grain with potassium iodide, after the external centres had been removed with chromic acid, laid bare sensitive centres which, on exposure, gave rise to a latent image, since development took place. Further treatment with chromic acid, however, removed these sensitive centres, and exposure did not recreate them or give rise to nuclei.

These experiments do not show what is the nature of these internal sensitive centres in unexposed grains, but simply indicate their existence. They may be similar to the surface centres, but do not come into play during the process of ordinary development, being imbedded in the grain. They may, on the other hand, consist of silver nuclei formed by incipient reduction of the silver bromide by the gelatin, the nuclei acting as a catalyst to photochemical decomposition during exposure. Further experiments are necessary, but with the present evidence there does not seem to be any need for ascribing a different nature to the internal and superficial sensitive centres.

The foregoing will, I think, indicate the difficulty of the questions of the latent image and of sensitive centres. This difficulty is further enhanced by the fact that the only method of showing the presence of the latent image and centres depends on the use of developers, which, of themselves, act in different ways. Questions of adsorption, etc., of the developer arise, but these cannot be entered into here.

Supposing that the nature of the sensitive centres and of the latent image were definitely settled, it would still be necessary to know the energy changes involved, that is, the amount of light energy absorbed by a single grain in order that a centre may be produced. Very little work has been done in this connection; the "print-out" effect has been studied to some extent, but the energy there involved is of quite a different order from that required for the formation of the latent image. The main difficulty lies in the measurement of the amount of energy absorbed by the grain. There remains, however, the possibility of measuring the relative amounts of energy absorbed when exposure is made to equal incident intensities of monochromatic light, as measured by a thermopile, and some preliminary experiments in this direction have been made by Toy. Slade and Toy have measured the absorption of fused silver bromide for the blue, violet and ultra-violet lines of the mercury vapour lamp, with wave lengths 4358, 4062 and 3650 Å.U. and found the ratios, neglecting reflection, to be 1 : 3.3 : 12.2. Now Wilsey has shown that the crystal structure of the salt which has been fused and allowed to solidify is the same as that of the grains in an emulsion, and therefore if the small size of the grains does not introduce any appreciable error, the greatest effect should be obtained with the ultra-violet and the least with the blue. Actually, the ratio of the number of centres produced was found to be 1 : 3 : 10.9.

If the absorbed energy is calculated, not in the same units for all wave lengths, but in terms of quanta, the theoretical ratio is 1 : 3.1 : 10.2, which is in very good agreement with the experimental value.

These results are shown in Fig.20. which at the same time shews the curve which should be obtained if the "light dart" theory were true. Toy suggests that since they have been obtained on the assumption that silver bromide is the absorbing material, they indicate that this is the substance actually involved in the formation of the latent image. The function of the traces of

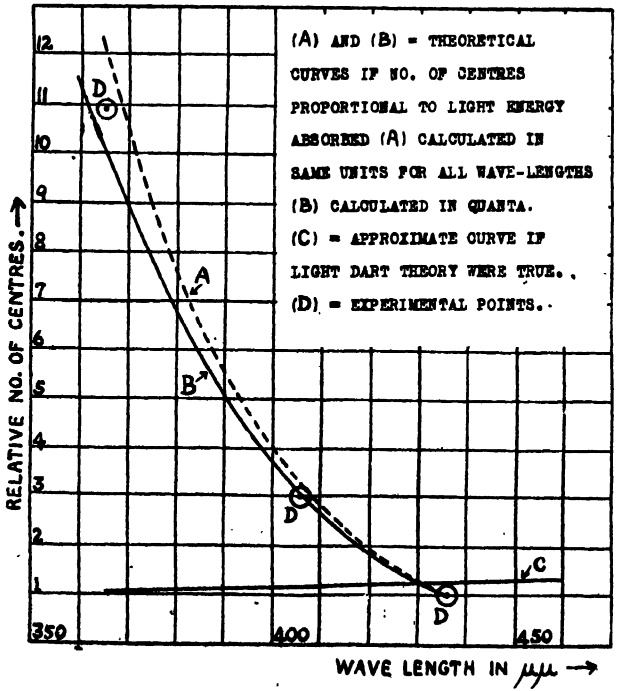

Fig. 20.

foreign matter, that is, of the adsorbed material, will then be to accelerate catalytically the photo-decomposition of the silver bromide. This would, of course, be in agreement with the ideas of Fajans. Much further experiment, however, is necessary.

Figs. 2, 3, 4 and 7, in Dr. Slater Price's course of lectures have been reproduced, by kind permission of H.M. Stationery Office, from the Descriptive Bibliography of Gelatin, published as Appendix 1. one of the First Report of the Adhesives Research Committee. The Society is also indebted to the *British Journal of Photography* for Figs. 8, 9, 11, 12 and 13; to *Science Progress*, published by Mr. John Murray, for Figs. 16, 17 and 18; and to the Faraday Society for Figs. 19 and 20.

NOTES ON BOOKS.

ORIGIN AND HISTORY OF ALL THE PHARMACOPEIAL VEGETABLE DRUGS, CHEMICALS AND PREPARATIONS, with Bibliography. Volume I, Vegetable Drugs. By John Uri Lloyd. Prepared under the auspices of and published by the American Drug Manufacturers' Association, Washington, D.C. Cincinnati: The Caxton Press.

The present volume is the first of the latest revision of a work which in its various stages has been recognised as one of increasing national importance in the United States.

It would seem that the mantle of our great pharmacologist, Dr. Pereira, has fallen on Dr. Uri Lloyd, a like spirit of the enthusiast and the zealot characterising both; thus the book becomes delightful to read and so technically important that no pharmacist, medical practitioner, general import merchant, or wide-viewed student, can afford to ignore it.

Only vegetable drugs are considered in Dr. Uri Lloyd's volume; chemical products coming under study in a second volume written jointly by Dr. Waldbott and Professor Heyroth.

The photographic illustrations, by Mrs. John Uri Lloyd and others, are 53 in number, and are printed on enamel paper as 28 inset plates; the first of these coming under the first cover, and so being anterior to the title page. The first photograph shows the two Ionic columns partly imbedded in the tangle where wild poppies and liquorice now grow: this being all that is now to be seen of the eighty columns which once graced the temple of Rhea or Cybele, the reputed mother of the Greek gods, and whose chariot we are told was drawn by four lions: indeed, all that now is to be seen of the richest city of old time, the renowned Sardis, the seat of the vast empire of Crœsus. In our author's note opposite this photograph, he concludes by asking what flowers of the field may one day trail over the buried glories of present time civilisation.

The East, which has given us the names and materials of so many vegetable drugs, comes to sight in the plate opposite p. 152: one photograph showing Turks digging liquorice root in the valley of the Meander, an old Roman road stretching across the background; and the other photograph showing the liquorice diggers at lunch, with the liquorice tangle as a background. Turning over a leaf we find two more views showing the valley of the Meander, so noted for wild liquorice; one of these photographs, includes the picturesque rock of Niobe on which is sculptured a prehistoric figure of the sorrowing mother. Rhubarb (p. 267) is an example of a Galenical originally from the Far East (China) as is more or less recognised by its name "*Rheum barbarum*," although by shifts and changes of meaning this term drifted to rhubarb from the Levant, and on p. 270 one may read the romance of rhubarb and the high prices arising from land transit over the breadth of Asia; for example, more than four times the price of saffron (in France, 1542).

Obviously, we cannot trace the general drift of sources from the Far East to the New World and the return gift of New World drugs to the East, as exemplified by the romantic story of Peruvian bark from its first use to the time of its cultivation in British India, pp. 62-63. Next following is a remarkably full and well-illustrated account of the uses and abuses of coca (the divine plant of the Incas), pp. 84-103, with three plates. In reading this account one cannot help feeling regret that humanity is so often deprived of the desirable and useful, by reason of misuse by the degenerate.

Scammony (p. 297) and Jalap (p. 176), give us an example of partly similar drugs: one from the East and the other from the West. Pharmacologists of antiquity, as Theophrastus and Dioscorides, also middle age writers, fully recognise the value of scammony as a drug, and the eminent Mynsicht, to whom the discovery of tartar emetic is generally attributed (see Watts's Dictionary of Chemistry, 1st ed., Vol. V, 1868, p. 648), after a general note on the merits of scammony, gives details as to the preparation of *Magisterium scammonii*, a precipitated resin of scammony and perhaps the earliest example of the isolation of the active principle of a vegetable drug. Details are given by Mynsicht in a late (third) edition of his *Armamentarium Medico-Chymicum*, a volume of 530 pages (of which 40 pages consist of index matter), published at Venice in 1696, but the West has given us in abundance and at a low price the active principle isolated by Mynsicht, it being a chief constituent of some kinds of jalap, especially of the so-called spurious jalap (*Ipomoea simulans*). Mynsicht's volume represents the views and practice of the Paracelsian School, or Spagyrists, as they termed themselves; and not only pharmacy, but also chemistry owes much to this school, so that a *fac-simile* reproduction of the text of Mynsicht's representative volume would probably be of use to those interested in the historical or the technical aspect. Owing to peculiarities in the text neither a reprint nor a translation would have the value of a *fac-simile.*

To return to Dr. Uri Lloyd's book, now under notice, the style is so good, so clear, pleasant and non-pedantic, with illustrations so telling and attractive as to make it eminently suitable for a reading book in schools.

TUTENAG AND PAKTONG: with notes on other alloys in domestic use during the eighteenth century. By Alfred Bonnin. Oxford University Press, Humphrey Milford.

This *édition de luxe,* in quarto, on Abbey Mills paper and with 29 plates at the end, is a remarkable and comprehensive study of the white Chinese alloys, their constituents, their uses, their history, and of the early attempts to manufacture them in Great Britain.

On page 45 our author points out that the general term in English should be "nickel brass," not bronze, the modern use of the term bronze indicating the presence of tin; or as we should prefer to define the matter, the presence of tin that functions as an effective or leading constituent; traces being left out of consideration.

Mr. Bonnin has exercised remarkable industry and skill in searching out historical details relating to nickel brass, its constituents and its part-parallels in industrial and artistic metallurgy.

The central area or display field of this delightful work is the latter half of the eighteenth century when British manufacturers made many articles of domestic use with the white alloys for which China has long been celebrated, and the white Bactrian coins mentioned in Mr. White's recent booklet on nickel (see *Journal* for April 27th, 1923, p. 413) rather suggest that the export of nickel brass from China has been carried on for considerably over two thousand years. Unfortunately, we have scarcely any records of the Bactrian industries, but it seems reasonable to conjecture that the Bactrian coins mentioned in Mr. White's book and commented upon in our columns, were made of alloy imported from China and consisting mainly of copper, four-fifths; nickel, one-fifth.

On page 41 of Mr. Bonnin's book we find an interesting account of Mr. Thomason's experiments at Birmingham, in 1823, on the imitation of the Chinese white alloy; the nickel addition to impure copper (copper to which iron had been purposely added) being in the form of the crude nickel of that time; a product very different from the almost chemically pure nickel of our time as prepared by the Mond process.

This alloy did not prove in all respects satisfactory, especially in respect to soldering, so active experimenting was discontinued, and some six years later a similar alloy was introduced into Great Britain from Germany; hence the term "German silver."

There is a temptation to linger over all the interesting quotations relating to the white brasses or nickel brasses, which Mr. Bonnin culls from our chemical sources of the past two centuries, but this is impracticable, and perhaps we may conclude with a note of sadness which often arises in the mind of the modern disciple of Vulcan (the metallurgical chemist), when he finds matters of keen interest to himself in an *édition de luxe.* He feels he requires three copies; one for careful preservation, another for his laboratory bench with a pencil on the open book, and still another which he can cut into slips for insertion into other books. If the purely technical matter and references to authorities of works like the present could be purchased in cheap pamphlet form, our modern chemist, the Tubal-cain or Vulcan of our day, would not feel this slight tinge of sadness in reading a delightful book.

WAX FLOWER MAKING IN VICTORIAN TIMES.

BY MARY SCOTT.

Of the many ways in which the 20th Century misunderstands the 19th, the present-day contempt for the gentle art of Wax-flower making is a notable (if minor) instance, and suggests how very active the historical imagination needs to be, if we are to comprehend aright the more distant past, when there is so much gross incomprehension of conditions obtaining a mere generation or two ago. Almost without exception, in conversation or in cold print, it is taken for granted that Wax-flowers touched the high water mark—or low water mark—of Early Victorian futility. Probably this disdain for an originally dainty art is due in part to the fragility of the material used (fine sheet-wax), and the consequent dilapidation of such flotsam and jetsam as may have lingered on to comparatively recent times, lurking in odd corners of a sea-side lodging or a country inn in ever dustier disrepute.

In reality, not only did the processes of Wax-flower making require considerable artistic ability, but botanical accuracy was a *sine qua non*; the correct reproduction of the character of the anthers for instance, as well as of such hidden details as the modelling of the base of a pistil, being matters of course. Actual flowers and leaves were carefully studied and the impress of the veining was transferred, when possible, from the living leaf to its waxen double. In schools where girls in the advanced classes were taught Wax-flower making, the subject was definitely connected in the curriculum with precise and accurate (though perhaps limited) botanical instruction, and the seeds of Nature lore were sown more than half a century before Nature study was boomed as the latest advance in education. It is well to remember facts like these before echoing the cheap and wholesale accusations of "artificiality" with which it is the fashion to label the Victorian era. There was certainly no element of pretence or deceptive intention in the making of Wax-flowers; they were wrought in all sincerity as faithful representations of floral nature and symbols of its beauty.

A further count in the indictment of the Wax-flower-maker's art lies in the too frequent combination of incongruous varieties—in season or out of season. It was a day of individualism, and it was each separate, individual blossom that was valued for its intrinsic colour or form—"massing" in decoration being an unknown canon of taste at that date. It may be argued indeed, and not without plausibility, that Nature herself uses a mixed palette much more often than she indulges in the complete "colour scheme" of a field of buttercups or a woodland drift of blue-bells

It was some time in the later sixties that the writer, as a child, was presented with a certain finely japanned Wax-flower maker's box, its partitions filled with fascinating sheets of sweet smelling wax, white and coloured, and all the various implements formerly owned by the giver It was a breathless moment when eager fingers were first instructed in all the delicate processes and a "garden pea" winged in purple and pink reality, at length emerged! It may be noticed in passing that the paper patterns, (cut from the actual petals) in the old box are on a distinctly smaller scale than the flowers of the present time, and this same pea-blossom, life size in its own day, would be deemed a very poor and feeble bloom now

It is the easy possibility of flowers in profusion all the year round that has long ago killed the desire of having them always with us in effigy. But if we "think back" to the conditions of life before say, 1850, when Wax-flowers flourished in their fragile prime, we may in a measure realise the value that any even passable representation of living flowers must have had in a world bereft of them for six months in every twelve. In the days of that old iniquity the window-tax,, only the rich might, in orangeries or pineries, keep a few special plants alive from season to season. But the older orangeries were little more than long stone galleries with large south windows and solid walls and roofs with flues in the walls for heating purposes. No conservatories: no greenhouses as we now know them: no florists' shops: no yearly influx of bulbs from Holland. Some few horticultural and nursery gardens there were, which would supply for perhaps 5/- the meagre half-handful of mixed blooms that, with fruit in addition, was (at least in the provinces) deemed sufficient decoration for the formal dinner party as late as the sixties and earlier seventies. On less important occasions, carefully polished apples and oranges, and other dessert fruits, decked with bay, laurel, or holly leaves (if one grew bay, laurel or holly) sufficed, while the ordinary daily dinner-table of our great grandmothers' young days was chastely furnished forth with its central cruet alone. The ceremonial silver and gilt epergnes of the period were usually devised for the lower tiers to hold fruit, terminating in a tall, narrow vase for a few precious blooms at the summit of all.

It was, of course, mainly due to Sir Joseph Paxton that all this was changed—and rapidly changed—when once the great Exhibition of 1851 with its "Crystal" Palace had familiarised people with glass-building and its possibilities. The remainder of the century saw the rise of glass in all its garden uses. but with the advent of the 20th century professionalism had already stepped in, florists had multiplied, and private people began to realise that it was both easier and cheaper to buy forced flowers than to grow them In addition to this, the pre-war tendency was increasingly in favour of house tenancy rather than ownership, and although since the war this condition has been reversed, the adding of glass-houses to the white man's other burdens is hardly likely to take place on any considerable scale in present circumstances. In the future we seem likely to depend more and more on the florists for winter flowers, using our summer gardens to grow our own favourites or to follow the cult of the moment.

In the winters of the writer's earliest recollections hyacinths were sometimes grown in water in special glasses, but in no great number or variety. In the summer things were better; but even in summer no gardenless folk had, or could obtain, cultivated flowers save by grace of friendship, and to those who had gardens, the earliest snowdrop and the first rosebud had an intensity of welcome and brought an intensity of delight, that is to-day quite unimaginable. Possibly in this fact lies some explanation of the undue fondness of our forebears for "natural" leafage in woodwork and ironwork, and even some atonement for their reckless indulgence in elaborately floral carpets and Berlin wool-work roses. However this may be, if we can conjure up the formal rooms carpeted all over; the good but massive furniture; heavy hangings; large and few pictures; and breadth of simple colouring unrelieved by any lighter touches, and at night time indifferently illuminated by gas or candles—then it becomes perhaps more possible to grasp the fact that they (our great-grandmothers aforesaid) were not entirely given over to idle folly, when they fashioned with delicate, loving touches, their marvellously accurate representations of the flowers they loved so well but could enjoy so briefly. They even loved them enough to prefer having them in wax and under glass shades, to foregoing them altogether. In the same spirit, exiles under tropic suns have been known to cherish a forlorn English daisy in a flower-pot!

(N.B.—The Wax-flower making box referred to above is now in the South Kensington Museum.)

MATCH PRODUCTION IN LATVIA.

The manufacture of matches in Latvia assumed considerable importance during 1923 as an export industry. At present there are six match factories operating in the country, producing an aggregate of 1,000,000 boxes of matches daily. Of this output 75 per cent. is exported, principally to the British market. Four of these plants are of major importance, employing approximately 750 men and producing close to capacity. The smallest is the only one utilising modern match-making machinery, so that the industry is still characterised by old equipment and methods. Movements are afoot, however, to modernise the industry.

From a report by the Secretary to the United States Trade Commissioner at Riga, it appears that the daily output of match splints for export from the six factories in operation reaches about 125,000,000, practically all of which is exported chiefly to England, Holland, Belgium, and Switzerland. With the expansion of the match-making industry in Latvia it is probable that the Government will protect it by planting uncultivated forest land with aspen timber—vigorously preserving present stands—and by prohibiting the export of match wood.

PRODUCTION OF ABACA IN THE PHILIPPINES.

The production and exportation of abaca, or manila hemp, were considerably greater in 1923 than in the previous year. There is no basis for an accurate estimate of the consumption of this product in the Philippine Islands, but the Manila Chamber of Commerce places the output of the local rope factories at approximately 24,000 bales, or about 3,000 metric tons. The method of estimate, however, is arbitrary, and it is possible that there is a considerable variation between this figure and the actual amount consumed.

According to a report by the United States Trade Commissioner at Manila, the rope factories are turning out a fairly large amount of cordage, but they are, for the most part, unwilling to give their production figures. The exports of rope, which totalled 2,631 metric tons in 1922 and 3,160 in 1923, consisted chiefly of cordage manufactured from maguey.

The best indication of the activity of the industry, and by far the most important phase of the trade, is the exportation of manila hemp, which amounted to 190,441 metric tons, valued at 49,903,150 pesos (peso at par = 2s. 1d.) in 1923, as compared with 172,026 tons, valued at 39,081,828 pesos, during the previous year, and 100,401 tons, with a value of 25,969,385 pesos, in 1921.

In the Manila market abaca is roughly classified into three main groups: US (United States) grades, UK (United Kingdom) grades, and those which are used both in the United States and the United Kingdom. The grades predominating in the United States, generally called United States grades, are A, B, C, D, E, F, and I, and those exported both to the United States and England are S1, S2, S3, G, H, and J1. Grades A, B, C, D, and E are used in the United States for making the higher-grade rope, such as is required for yachts, the United States Navy, and other purposes for which a specially good quality is needed. F and I are the staple grades in the United States for the rope used in the merchant marine. Other rope grades are D, E, and F, S1, S2, J1, G, S3, and H, all of which are used in varying proportions in order to level the quality and colour for the various grades of rope manufactured. The grades used in the United States for making binder twine are S1, S2, J1, G, S3, H, and sometimes I. Grades G, S3, and H, while of good quality, are of a more or less dark colour, and a considerable portion of these lower grades is made up into yarns which are tarred. Colour, therefore, is not a selling factor. In the customs returns, grades J1 and J2 are returned under the general name of J.

The following table shows the exports of the principal classes of abaca to the United States for the years 1920 to 1922:—

Grades	1920	1921	1922
	Kilos	*Kilos*	*Kilos*
A	52,626	25,554	84,884

GENERAL NOTE.

Motor Transport in Bulgaria.—There are approximately 4,000 miles of roads in Bulgaria, and even before the war the best of them were no better than the average English second-class road. Now, owing to lack of labour and capital, all roads in Bulgaria, judged from English standards, are bad. According to the report of the Secretary in charge of Commercial Affairs at the British Legation, Sofia, the usual method of transport is the ox-cart, but since the war motor transport has made a small but steady headway, and there are now some 900 touring cars and 400 lorries in the country. There is a demand for a cheap touring car, capable of holding six people, and which shall be strong enough to stand the road conditions. At present, there are not more than half a dozen British cars in Bulgaria. As, however, old motor stock which came into private ownership on the conclusion of the war becomes worn out, there will be a steady demand for replacements, and British firms which could compete in price with popular Continental makes would find an opening in the country.

CANTOR LECTURES.

A STUDY OF THE DESTRUCTIVE DISTILLATION OF COAL.

By **Edward Victor Evans**, O.B.E., F.I.C.,
Chief Chemist and Products Manager, South Metropolitan Gas Company.

LECTURE I.—*Delivered February 25th*, 1924.

It is with considerable temerity that the author addresses you on the subject of the destructive distillation of coal, and his ability to do so may be open to just criticism in view of the fact that his first-hand experience in these matters is confined to the carbonisation of coal in horizontal retorts, and does not comprise the working of vertical retorts and the manufacture of water gas. It is proposed, however, to deal mainly with the principles underlying the process of carbonisation, and it is believed that these do not vary so fundamentally in the different systems that these lectures will fail to render some service to the gas and allied industries.

In the Cantor Lectures of 1919, Prof. Bone dealt in a comprehensive way with the general question of coal conservation, and the author desires, though perhaps in a less direct manner, to make a further contribution to this subject mainly from the viewpoint of a chemist in the gas industry. It is proposed in these lectures to regard the destructive distillation of coal as a true chemical process, the raw material being the therms constituting the potential heat energy of the coal, while the process itself consists in the distribution of this energy into more useful and more economic forms.

The introduction of the therm system met with a cold reception at the hands both of the public and of the gas industry, but to-day this has given place to a quiet acknowledgment of its value. It is not the consumer alone who benefits by the therm system, for in the industry itself the new interpretation of results is leading to increased efficiency. At first the computation of working results on a basis of therms per ton of coal carbonised rather than cu. ft. of gas of standard calorific value was somewhat resented, since it was felt that there was essentially no difference in the two methods of stating results. Fundamentally there is no difference, yet it is probable that the adoption of this system is likely to constitute a very great step in the appreciation of the coal conservation problem. Though there is no intrinsic difference, the gas manufacturer to-day sees more clearly that the ship, barge or wagon bringing coal to his works is delivering a load of therms, a certain proportion of which may be distilled off by heat, and that it is his duty to distribute these therms so carefully between gas, tar and coke, or coke, tar and gas, as the case may be, that the process may be carried out with the maximum conservation of thermal energy.

The author's experience in the working up of chemical by-products has brought him into the closest working relationship with the chemical industry, and he has observed that the chemical manufacturer approaches his task with a materially different outlook from that of the manufacturer of gas, who, in the past, has not universally realised that he is operating what is essentially a chemical process. In the chemical industry few reactions are carried out on the large scale to give the full theoretical yield of product, but a fierce struggle exists among chemical manufacturers to attain the highest possible yield, as their power to compete in the open market is largely determined by the efficiency of the process adopted. The amount of aniline made from unit weight of benzol, the amount of beta-naphthol from naphthalene or of anthraquinone from anthracene, is measured and controlled with the greatest diligence. The chemical industry can only flourish if these principles of conservation, necessitating a maximum yield of products together with complete utilisation of by-products, are studied and developed day by day. The gas engineer to-day realises that his task differs from that of the chemical manufacturer only in the fact that he deals in therms and that his efficiency to compete depends upon his ability to market solid, liquid and gaseous therms in the most economical way. Each new development in the knowledge of the constitution of coal or of its behaviour under heat—whether it be derived from the University of Leeds, the Imperial College of Science, the Fuel Research Board or the gas industry itself—reveals the true chemical nature of the coal distillation process.

Obviously the major duty of the gas technologist is to manufacture gas, but this responsibility should not cause him to overlook the fact that it is always possible to distribute the therms of the original coal between gas, tar and coke in a variety of ways. The nature of the distribution is determined by the type of process adopted and by the conditions of its operation. During these lectures it is proposed to deal with these two aspects of the process of carbonisation. For the moment, it will be agreed that in the interests of the main product—coal gas—it is essential that the utmost attention should be devoted (as in the chemical industry) to all subsidiary products. When it is generally realised that these subsidiary products are sources of potential therms, they will be placed in a position only just second to that of gas, and the word "residual," will, it is to be hoped, entirely disappear from the industrial vocabulary and be replaced by the term "by-product."

In pursuing this interpretation of the carbonisation process as one in which the original thermal energy of the coal is distributed into more useful and economic forms, it is interesting to study the distribution effected on the one hand by high and on the other by low temperature carbonisation. Fig. 1 represents the general distribution of therms in each process, the coal being assumed to contain 300 therms per ton.

In the case of high temperature distillation (without the admission of steam), 1 ton of coal containing 300 therms will yield about 72 therms as gas of 560 B.Th.Us. per cu. ft. and some 17 therms as tar, leaving coke containing about 199 therms. The process loss will be of the order of about 12 therms. It will be observed that the loss in the case of low temperature carbonisation is of the order of 16 therms, as compared with 12 therms in high temperature carbonisation. The loss of therms from the original coal substance is due in both cases to the fact that the heat required for distillation is not taken wholly through the walls of the retort, but is partly supplied from the coal substance itself, principally during the early stages of its carbonisation. It is, therefore, not surprising to find that the loss experienced during the low temperature process, when exothermic reactions predominate, is greater than in complete carbonisation, where the loss due to the liberation of heat during the exothermic period is partly neutralised by the conversion of sensible heat into potential heat at the higher temperatures. The low temperature carbonisation of 1 ton of coal containing originally 300 therms yields some 35 therms as gas of 1090 B.Th.Us. per cu. ft. (3200 cu. ft.) together with 26 therms as low temperature tar, and 223 therms as coke still containing 9.3% of volatile matter. Determinations made upon low temperature fuel containing about 10% volatile matter have shown that the 9.3% of volatile matter remaining in the coke would represent about 29 therms per ton of the original coal. Now if this potential volatile matter be added to the amount actually obtained, there is practically no difference in the yield of so-called volatile therms and coke therms in the two methods of carbonisation. Such slight difference as does exist is to the advantage of high temperature carbonisation but this may be fortuitous. There is, of course, a difference in favour of low temperature carbonisation represented by the somewhat lower fuel consumption required for the process of distillation, but the by-products, gas and tar, and even the solid fuel

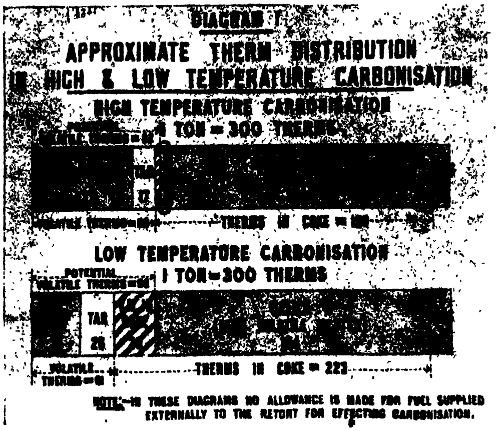

FIG. 1.

itself, must not be utilised for this purpose; the therm in its cheapest form should be employed, as is the case with coal gas manufacture.

From these results, which have been obtained from the same sample of coal, it would appear that the low temperature process is not superior from the point of view of efficiency of distribution. It simply results in a different distribution of the thermal energy of the original coal—it is the high temperature process arrested. This is a most important observation, in view of the fact that the pure chemist is naturally inclined to believe that high temperature carbonisation, involving as it does drastic decomposition of the coal substance, is a wasteful process, and that the low temperature treatment is more conducive to the conservation of the energy of the coal substance. It is known that drastic decomposition can and does take place, and this subject will be dealt with later. Provided, however, the high temperature process is conducted so as to obtain yields similar to those indicated in the diagram, there would appear to be no ground for supposing the low temperature process to be definitely superior from the point of view of conservation of energy.

The 29 therms of potential volatile matter retained in the low temperature coke are subsequently burned in the household fire as a low calorific value gas, for there are no complex hydrocarbons to be distilled away or partially burned with the production of soot or smoky flames, as is the case with ordinary household coal; the material is, in fact, a coal-gas coke mixture. There is no wonder, therefore, that agreeable results are obtained, but the question is whether the consumer of this fuel can afford to pay for the potential coal gas left in it. Apart from the technical difficulties involved, the problem of low temperature carbonisation is largely one of economics. Coal is conveyed to, and lifted into, the retort, heated to a temperature of some 600° C., 61 therms of volatile matter per ton distilled away, and the material remaining subsequently cooled and discharged. If this process were carried out at a higher temperature, and for a slightly longer period, thus entailing no appreciable increase in labour costs, the volatile matter would be converted to gaseous therms and sold at the ruling price of gas per therm. There is not likely to be an appreciable difference between the value of the therm in high and in low temperature gas and, unless the tar produced in the low temperature process commands a higher value on the thermal basis than high temperature tar, it would appear that the consumer of low temperature fuel must be prepared to pay for practically the whole of the potential volatile therms at their true gas price before the process of low temperature distillation can be expected to be as remunerative as that of high temperature.

This somewhat lengthy analysis of the low temperature process has been introduced partly for the purpose of demonstrating the fact that the destructive distillation process should be viewed as a means of converting the energy of the original coal into therms of different value distributed between the various products, partly with the object of proving the value of the therm interpretation of carbonisation results and finally to prepare the way for demonstrating that the manner of distribution of the volatile therms—whether as gas, tar or as part of the solid fuel—is controllable and may be altered or adjusted by the method of distillation adopted.

It is now proposed to deal with the loss of gaseous therms which frequently takes place in carbonisation practice. The secret of preventing wastage of gaseous therms and of conserving the energy of the original coal lies in the possession of a suitable design of retort bench fittings and accessory plant, and in the maintenance of these in the highest possible state of efficiency and repair. This cannot be over-emphasised, for in the gas industry there are many investigators striving to devise processes which shall represent a superior degree of coal conservation during the distillation process, whereas the author believes that what can be done in this respect is small compared with the economic advantages to be gained by increasing the efficiency of working results from existing installations.

In the design of retort settings the engineer and chemist agree that the following requirements are essential:—

(1) That the distribution of heat throughout the length of each retort should be fairly uniform.

(2) That the temperature should decrease sharply at the ends of the retort.

(3) That the rate of transmission of heat

through the wall of the retort should be practically the same in the case of all retorts in one setting.

(4) That the retort should be of such dimensions that complete carbonisation of the coal charge is possible, and whatever be the mass of charge decided upon, it is naturally of great consequence that it should lie evenly throughout the retort. This latter factor is, of course, dependent upon well-designed and well-operated charging machinery.

This list of requirements could, as is well-known, be materially expanded. A technical chemist accustomed to making chemical and physical determinations in the retort-house possesses concrete ideas of the fundamental requirements in the design and working of furnaces and retort settings, and is appreciative of their influence upon the final carbonising results. He is thus able to indicate sources of loss, and the conditions which produce unsatisfactory process yields, but his ability to design or re-design large scale retort settings and plant, in order to attain the required end, is limited. So far as the author's experience goes, the desired adjustments are better left conjointly in the hands of the technical chemist and of the observant gas engineer, the latter, by a process of trial and error in the design of retort settings, having become master of the subject.

The question of the effect upon thermal yield and upon the constitution of the gas, of maintaining in a state of good repair the retort and its external fittings, is one to which considerable attention has been given by the author. Carbonising trials have been carried through both in sound and in leaky retorts, and the effect of different types of leaks upon the volume, calorific value and composition of the gas produced has been examined. These trials have been conducted in an experimental plant in which it was possible to carbonise 3 tons of coal per day. A typical Durham gas coal has been used throughout, and the conditions maintained have been such as to reproduce results normally obtained by carbonising 10 cwt. charges in 20 ft. retorts for a period of 10 hours, with a combustion chamber temperature of 1320°C. The vacuum maintained during the period of carbonisation was 3/10″ water pressure, obtained by the maintenance in the hydraulic main of 13/10″ vacuum and 1″ liquor seal.

It will first be necessary to examine some typical carbonising results obtained, under these conditions, in tight retorts, and fig. 2 shows an average result obtained under the stated conditions. The gaseous thermal yield is of the order of 73.5 therms per ton, the total volume of 566 B.Th.Us. gas produced being 13,000 cu. ft. The first curve shows the volume of gas produced hourly and the second curve the gradual decrease in the calorific value of the gas during the period of carbonisation. One is at once impressed by the small amount of useful work effected in the last few hours when the rate of heat transmission through the walls of the retorts has been considerably reduced, and an examination of the analysis diagram, which

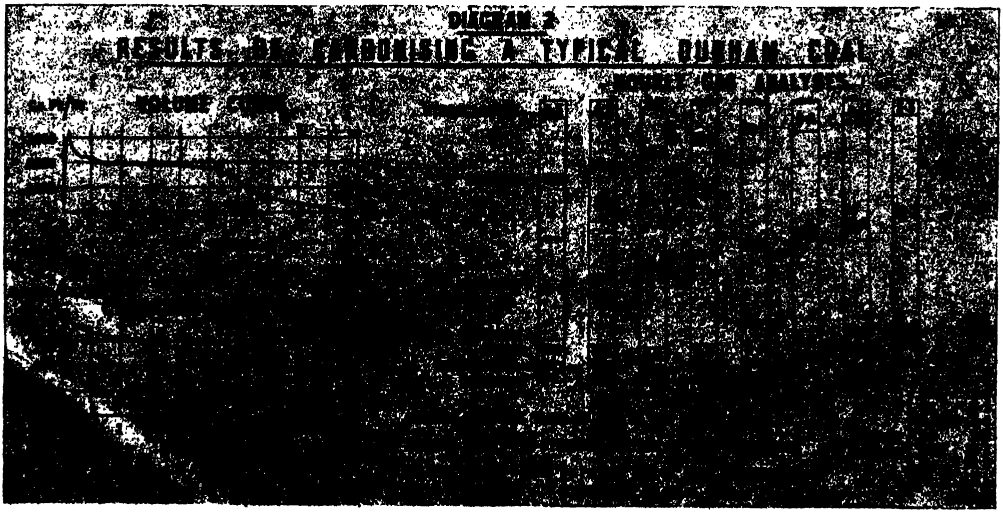

FIG. 2.

indicates according to the known method of presentation, the hourly changes in the constitution of the gas, confirms this impression.

The author has found that a convenient method of examining the amount of useful work effected during each hour of the carbonising period is to produce a thermal model. This is constructed by combining the hourly volume and calorific value curves of fig. 2. In fig. 3 it will be seen that the length A of the thermal model represents the time of carbonisation in hours, while the height B represents the volume of gas produced per hour and the breadth C the calorific value. The value of this means of representation is, in the first place, that the mass of the model itself is proportional to the thermal yield of gas from the coal, and, secondly, that a section taken at any one period shows in its area the amount of work being done at that instant. Fig. 4 shows sections of the model taken from the middle 10 minutes of the first and last hours of the carbonising period, and the immense difference that exists in the amounts of useful work done in each case will be noted.

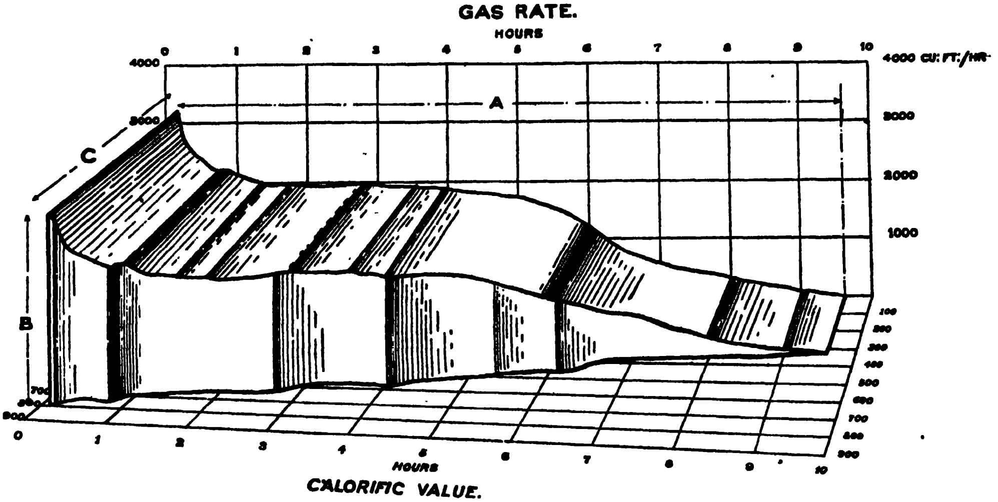

FIG. 3.

SECTIONS SHOWING THERMAL YIELD DURING MIDDLE 10 MINUTES OF FIRST AND LAST HOUR OF CARBONISING PERIOD.

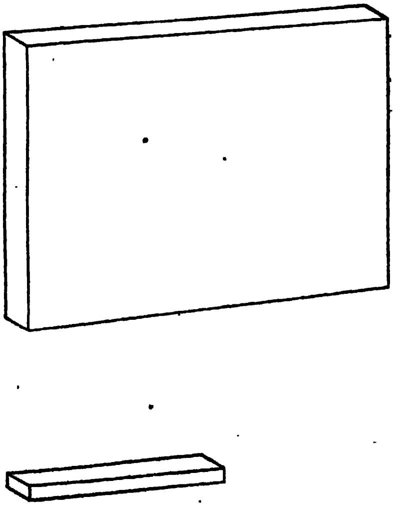

FIG. 4.

The thermal model shown in fig. 3 is constructed from a series of carbonising trials on an experimental plant, but the results are comparable with those which may be obtained in average practice. As indicated before, one of the outstanding observations to be made is the large volume of gas of very high calorific value evolved in the first ten minutes after closing the door of the retort. In this period 5.04% of the total gaseous therms is produced, and knowing that the constituents of such a gas are unlikely to be sufficiently stable to withstand contact with the heated sides of the retorts, it was decided to attempt to apply a much higher vacuum during this early stage of the carbonising period for the purpose of preventing decomposition. Carbonising trials were carried through in which there was an initial vacuum of 20/10", which was reduced by 3/10" every 10 minutes, until the normal vacuum of 3/10" was attained. There was thus a gradually decreasing vacuum — higher than the normal — operating during the first hour

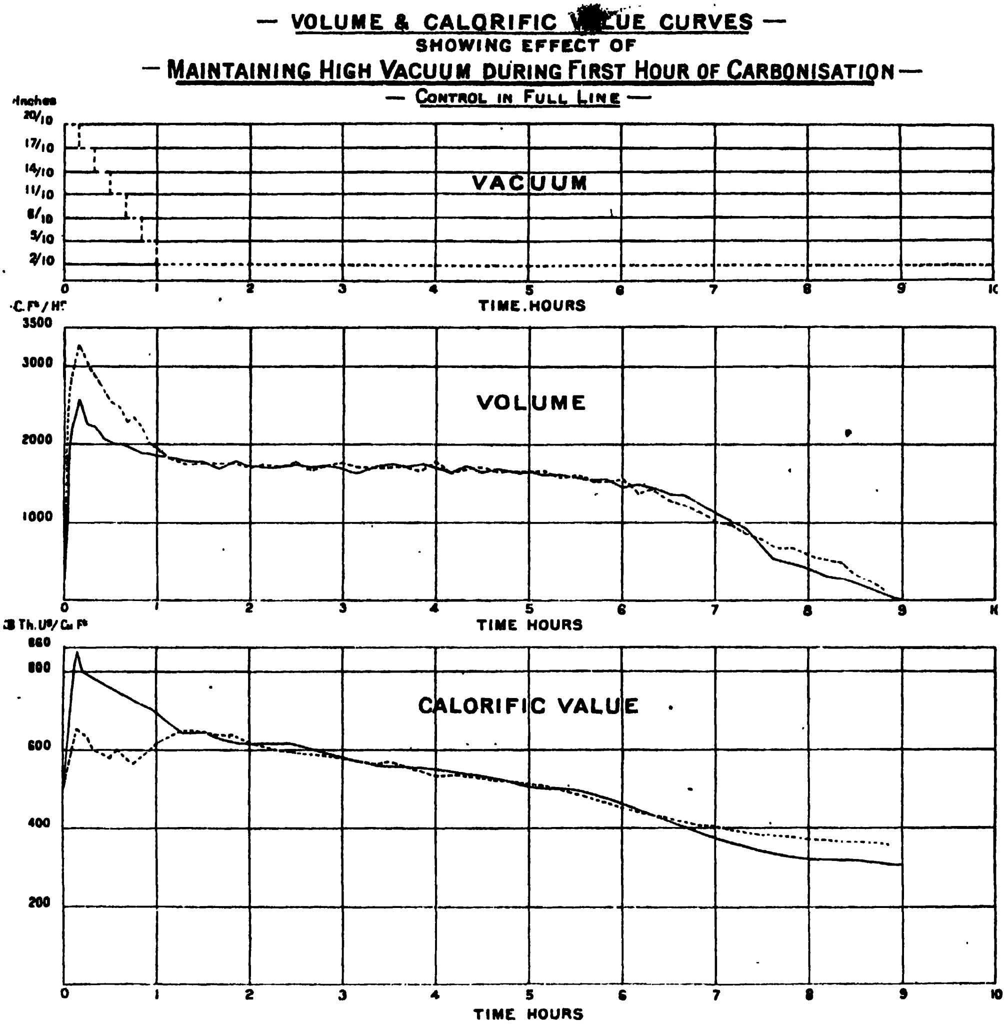

Fig. 5.

of carbonisation, while the normal vacuum was maintained throughout the remaining carbonising period. These conditions proved successful in materially reducing the calorific value and extending the volume of gas made during the early stages of carbonisation (fig. 5). The full line curve represents the control experiment carried out under normal conditions, in which case the average calorific value of the gas was 563 B.Th.Us. and the yield 73.5 therms per ton of coal. A comparison of the resulting thermal model with that obtained under standard conditions also emphasises the effect of the new conditions upon the calorific value and volume of the gas produced (fig. 6). In the carbonisation trial, under these special conditions, the average calorific value of the gas was 542 B.Th.Us. and it is disappointing to observe that there was no apparent improvement in the gaseous thermal yield. It would appear from this and a number of similar experiments, that, provided the retort is tight and in good condition, little advantage is likely to materialise from the adoption of a procedure of this nature. Had there existed a hole or cracks in the retort, this method of working would be expected to prevent losses from the retort when the rate of evolution of gas is at its highest. The procedure is, however, only of academic interest, for it is not generally possible in gas-works practice to produce a high pull only in those retorts which have been newly charged.

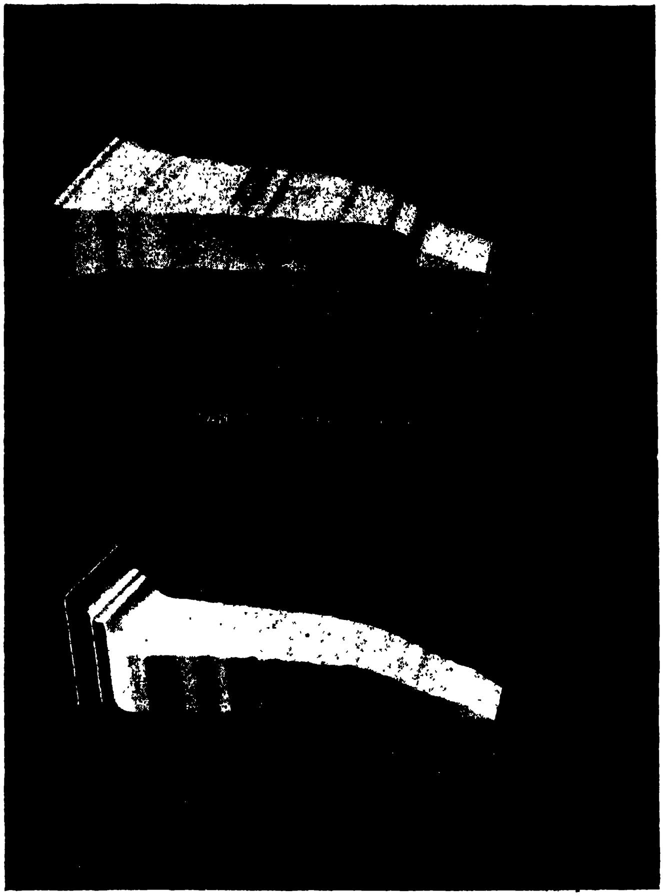

Fig. 6.

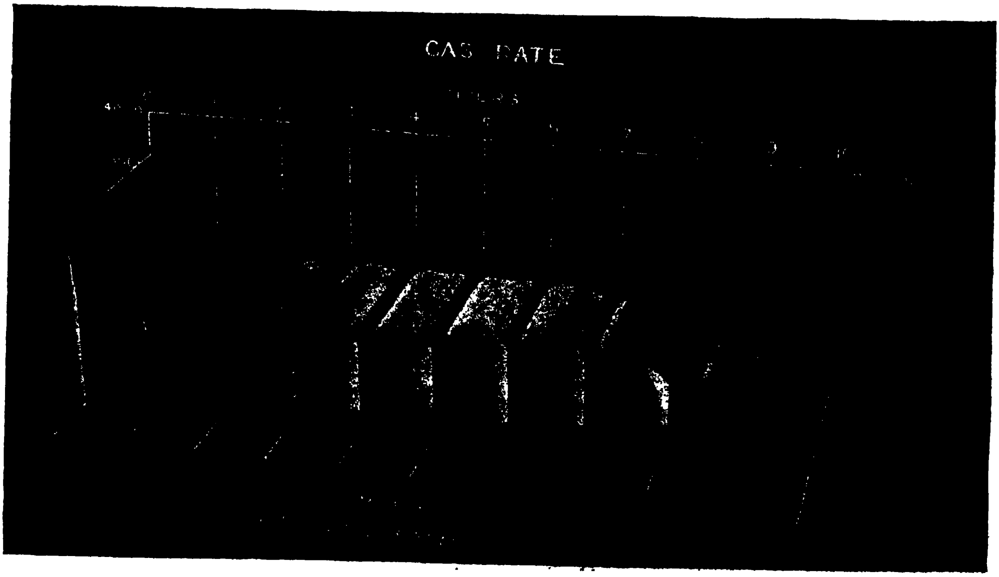

Fig. 7.

The thermal models constitute an excellent device for detecting any slight differences in the carbonising process, or for determining the effect of any adjustments of the conditions of working. The model shown in fig. 7 furnishes an example of the sensitivity of these models. It demonstrates results obtained from normal carbonising procedure. For obtaining a high thermal yield it has been found necessary to reduce the vacuum in the hydraulic main of any one section to level gauge when some of the retort doors of that section are open for charging or discharging. As hourly charging is adopted, it is thus the practice to reduce to level gauge for 10 minutes during each hour. An examination of the thermal model will show that at these periods there is a definite indent in the volume curve, and that immediately following this, when the vacuum is re-established, there is a corresponding peak in the calorific value curve. It is evident, therefore, that gas has been accumulating in the retort during this period of level gauge. Generally speaking, provided the retorts are tight, this method of procedure does not materially affect the thermal yield of gas. It will be demonstrated later how disastrous is this practice in the case of an unsound retort.

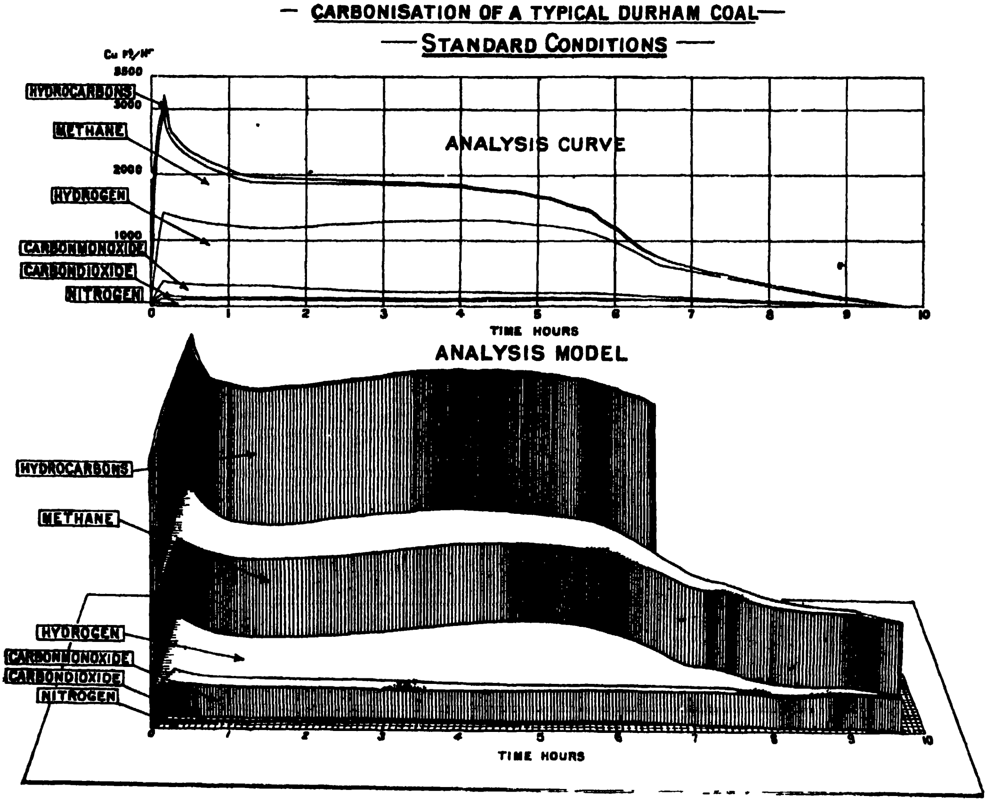

Fig. 8.

In order to show clearly the composition and thermal value of the gases obtained by carbonisation under normal conditions, it is possible to construct from the time/volume curves an analysis model for the various gaseous constituents. The lower portion of fig. 8 shows the structure of such a model, which is composed of various sections representing the different constituents of the gas, the height of each section representing the calorific value of the constituent, and the breadth of the section the volume of that constituent produced at any one moment during the whole period of carbonisation. Thus, at any given time during the carbonisation process, it is possible by reference to the appropriate section of the model to observe exactly to what extent any constituent is contributing to either the volume or the calorific value of the gas being evolved. It is evident that, by looking down on the model in plan, a simple reproduction of the stratified analysis curve will be seen, and the analysis model is produced by making the height of each constituent proportional to its calorific value.

From this analysis curve it will be seen that the production of inert constituents is fairly constant up to the seventh hour; carbon monoxide is evolved fairly evenly until the eighth hour, when it gradually becomes less in quantity, while hydrogen gradually increases during the carbonising period until a maximum is attained in the region of the fourth hour. Methane production is at its height during the first ten minutes and falls off sharply until, at the end of the second hour, a fairly constant quantity is being produced. The unsaturated hydrocarbons, important though they are as regards their contribution to calorific value, are quite small in volume and tail off at the sixth hour. Whereas the analysis curve shows the hourly production of each constituent of the gas, the analysis model demonstrates the contribution of each constituent to the total thermal yield and also to the effective work, at any one moment during the whole carbonising period. It thus shows in a convincing manner the true value of each constituent. In the case of the inert constituents, nitrogen, carbon-dioxide, and oxygen, it is obvious that as these possess no calorific value they will be represented without height in the model, and it will be seen that they are shown at the foot of the model possessing area only. The most outstanding feature of this model is the layer representing the unsaturated hydrocarbons which disappears at the end of the sixth hour. This layer has considerable height owing to the high calorific value of the unsaturated compounds, but is practically a knife edge owing to their small volume.

Reverting now to the soundness of the

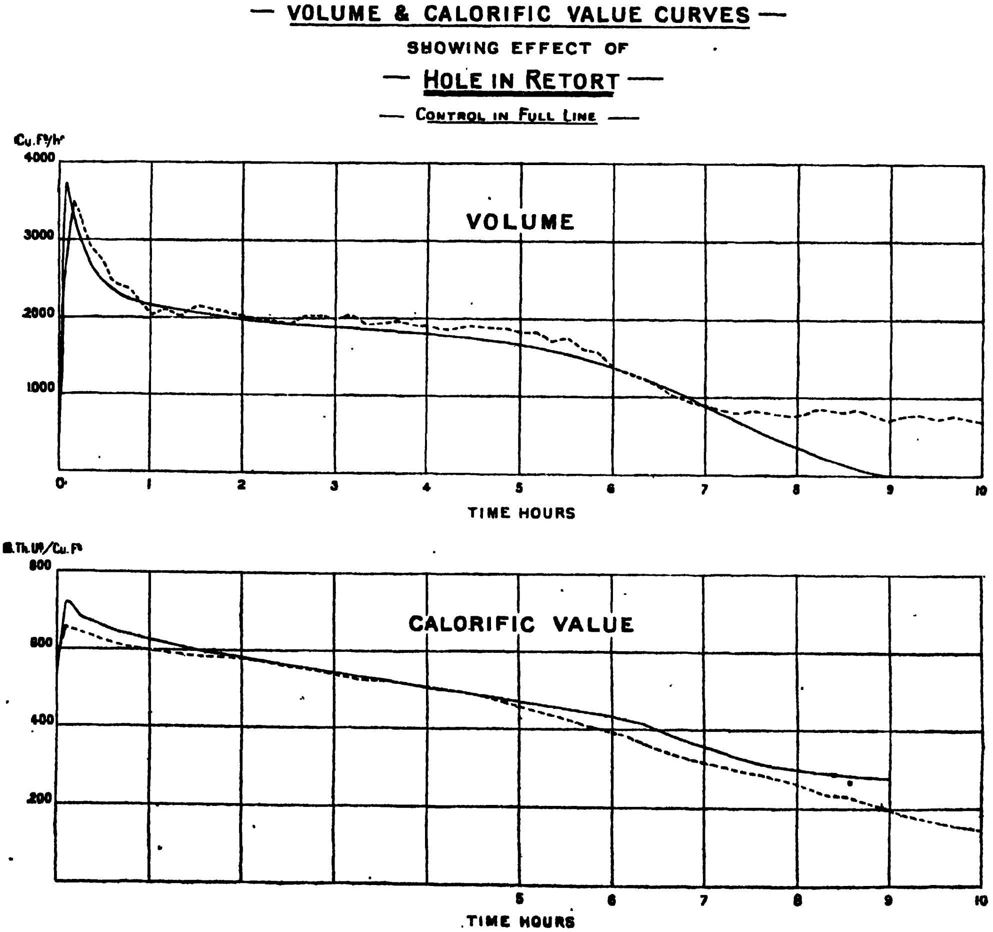

FIG. 9.

retort and its effect upon the nature of the gas made and the yield of gaseous therms, fig. 9 represents the results obtained from working under standard conditions—*i.e.*, with a continuous pull of 3/10″—but with a hole of ½″ diameter in the top of the retort at a point equivalent in position to the centre of a 20ft. retort. The broken curves show, in comparison with the control curves, the changes in volume and calorific value resulting from the hole in the retort. It will be seen that, whereas the volume peak is reduced at the commencement of carbonisation, due to the loss of the rich gases through the hole in the retort, the volume is increased throughout practically the whole of the remaining period of carbonisation. This increase is probably due to the entry of furnace gases, which will not only add to the volume but may also lead to more rapid carbonisation taking place as the result of their scouring action. On the other hand, the calorific value of the gas is lower throughout the whole period of carbonisation, the calorific value of the final gas being 482 B.Th.Us. as against 532 B.Th.Us. in the control experiment. The most interesting observation to be made, however, is that the manufacture of gas does not stop at the tenth hour, for at this period there is being produced about 700 cu. ft. per hour of a gas of 180 B.Th.Us. per cu. ft. This gas is producer gas, as will be seen from an examination of the analysis curve and analysis model (fig. 10). A comparison of these curves with those obtained from a normal carbonisation demonstrates most clearly the actual differences in yields of the various constituents of the gas. The most interesting section of the analysis curve is that relating to the last few hours of carbonisation, where the effect of the producer gas reaction is clearly shown. The large increase in the nitrogen content of the gas passing over in the final stages is to be expected, but it is surprising that the time of contact in the retort is sufficient to convert the carbon-dioxide of the waste gases to carbon monoxide, at the expense of the coke.

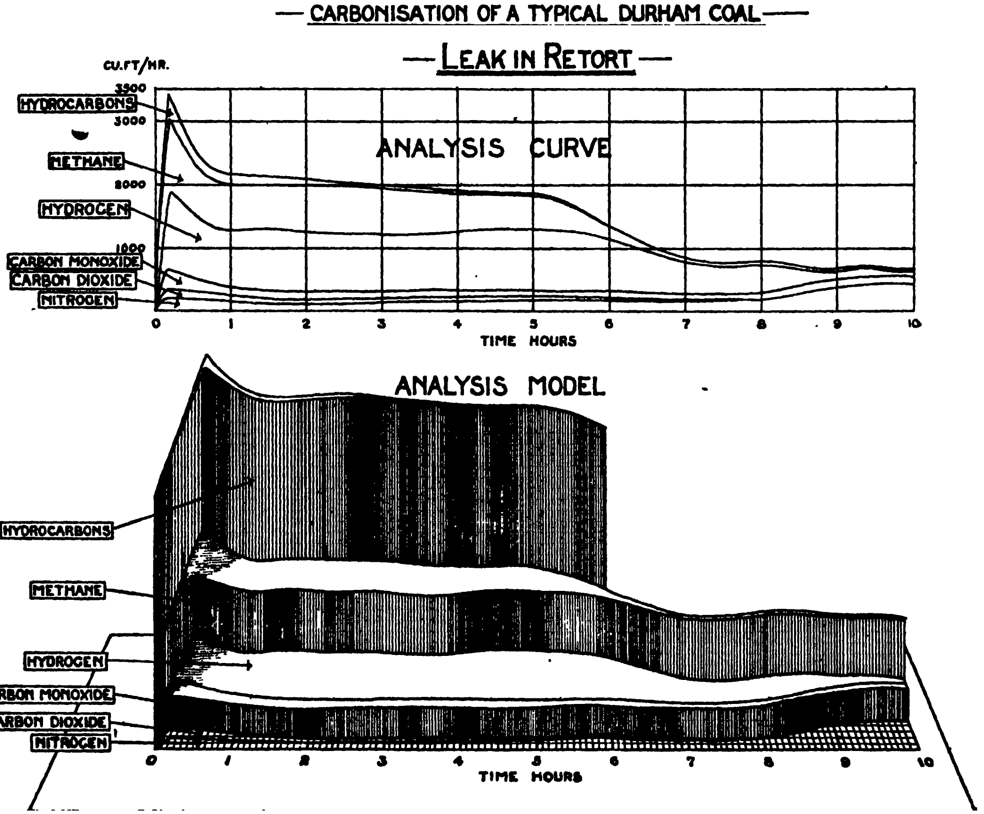

FIG. 10.

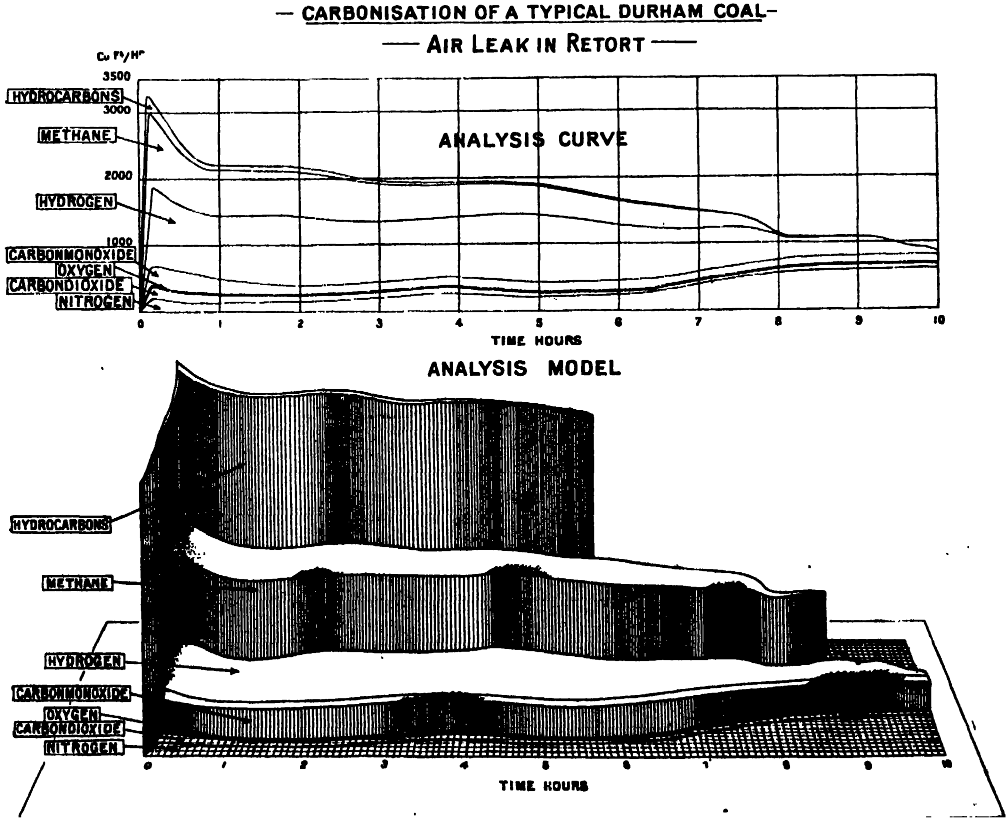
The thermal yield of gas will be dependent upon the time the charge is allowed to remain in the retort and in the above test it amounted to about 75 therms per ton. It is a very difficult matter to determine what is the precise thermal yield of true coal gas under these conditions of carbonisation, for it would be required to know at what stage of the process the producer gas reaction commenced. Rough calculations from the analyses show, however, that 1 to 2 therms of true coal gas have been replaced by producer gas therms. By continuing the carbonisation process and increasing the quantity of producer gas formed it is possible to obtain results apparently superior to those obtained in normal practice with tight retorts. If, however, it be desired to admix producer gas with coal gas for the purpose of dilution, it would be a far more economical process to manufacture the producer gas in the producer itself, and to add it under control (of course, preferably through the charge itself), rather than to cause the reaction to take place as the result of the indiscriminate admission of waste gas through holes or cracks in the retort; the heat required for the reaction has to be supplied through 3″ of fire-clay and the manufacture of producer gas from waste gases in a gas retort under these conditions is a costly process. It will thus be seen that by manufacturing coal gas in a pierced retort it is possible to obtain an excellent thermal yield of gas and, in addition, a volume yield which might be very useful to manufacturers who continue to sell on a volume basis.

Before leaving the subject of the effect of a ½″ hole in the retort upon carbonising results, it should be noted how different must be the results obtained from retorts in which there exists a larger or smaller hole than that selected above, or where the holes are at points different from that in the foregoing example. It stands to reason, for example, that a hole in the retort in close proximity to the ascension pipe would not give conditions conducive to the producer gas reaction. There is but one conclusion to be arrived at, and that is that in the interests of high gaseous thermal yields all retorts should be



— CARBONISATION OF A TYPICAL DURHAM COAL —

— AIR LEAK IN RETORT —

ANALYSIS CURVE

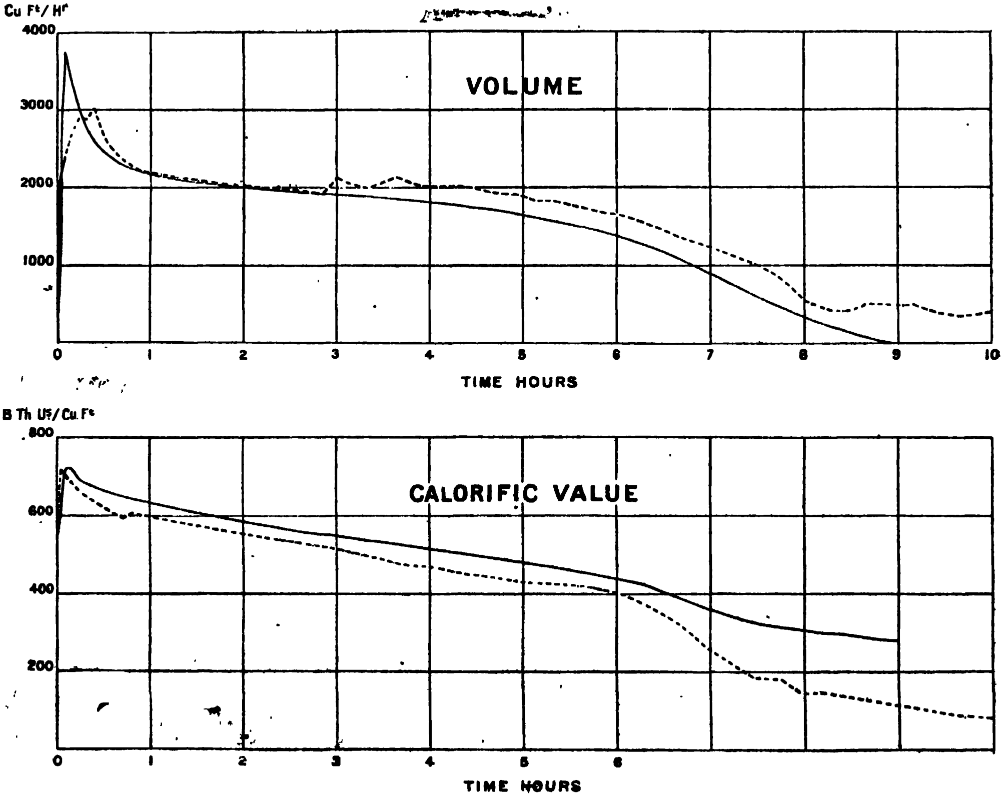
ANALYSIS MODEL

FIG. 11.

maintained in a high state of repair. If it is desired to admix water gas or producer gas, it is certain that this is best done by its admission through the charge as it is undergoing carbonisation, or failing this, by subsequent admixture, but it should always be done under perfect control by means of a regulating valve.

However great may be the disadvantage of drawing into the retort waste gases from the retort setting, the admission of air to the gas before it has cooled below the ignition point of all of its constituents is more than ever to be avoided. Before, however, passing to a consideration of the results of admitting a small quantity of air to the gas before it passes into the ascension pipe, it may be of some interest—perhaps mainly academic—to note the effect of allowing a small current of air, as distinct from waste gases, to enter into what would practically be the centre of a 20 ft. retort. The air introduced eventually does considerable damage, as may be seen from an examination of the analysis curves and model (fig. 11). The destruction of the hydrocarbons by the introduction of oxygen is indicated by the high carbon dioxide content of the gas throughout the whole period of carbonisation, while the producer gas reaction appears to proceed in much the same way as in the pierced retort. The total yield of hydrogen is smaller than in the case of the introduction of waste gases, while the high nitrogen content of the gas passing over towards the completion of the carbonisation is again an outstanding feature of the curve. The final result of the procedure is to manufacture 17,300 cu. ft. per ton of coal carbonised, the calorific value of the gas being 419 B.Th.Us. per cu. ft., and the thermal yield about 70 therms per ton.

A yield of 70 therms per ton is far from a poor one, but if this coal were carbonised in



— VOLUME & CALORIFIC VALUE CURVES —

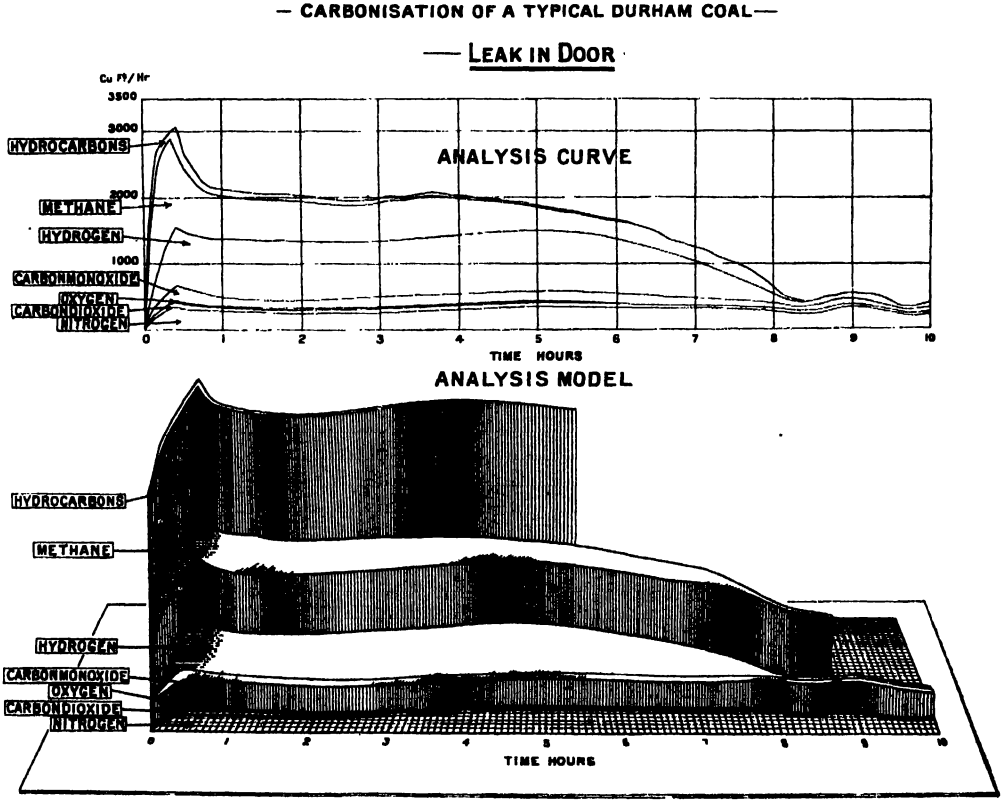
SHOWING EFFECT OF

— LEAK IN DOOR —

— CONTROL IN FULL LINE —

FIG. 12.

a tight retort, and there were added such a proportion of producer gas as was made during the carbonisation process in this example, the final result would probably be at least 75 therms per ton. It may be imagined that what has actually happened is that about 5 therms per ton of coal have been destroyed in the retort, reducing what would have been a 73 therm yield to 68, but that some 2 therms of producer gas have been added at the expense of the burnt out products in the retort. The real conclusion to be drawn from an experiment of this nature is that the gaseous thermal yield per ton of coal carbonised is, when taken by itself, no indication whatever of the efficiency of the process or of the degree to which conservation of thermal energy has been practised.



— CARBONISATION OF A TYPICAL DURHAM COAL—

—— LEAK IN DOOR

FIG. 13.

In order to determine the effect of admitting a small quantity of air into the gas before it passes into the ascension pipe, one door in a through retort was wedged with a 1/32″ distance piece, whereby a mean slit of 1/64″ was produced over the whole door oint. A totally new set of conditions is experienced by allowing a small quantity of air to be introduced at this point. The volume curve (fig. 12) again shows that a quantity of rich gas is lost in the initial stages of carbonisation, while the volume of gas obtained during the last few hours is considerably increased. The calorific value of the gas is also appreciably lower than that obtained under normal conditions. The analysis curves and model (fig. 13) show that there must have occurred a very different set of reactions from those in the foregoing examples of leakages, and the variation in results is attributable to a multitude of reactions which are taking place in the ascension pipe. The two outstanding points to be observed in the analysis model are that the hydrogen yield has appreciably decreased, particularly towards the end of the process, due probably to its conversion into water vapour by combustion in the ascension pipe, while the oxygen content of the final gas is practically the same as in gas obtained from a tight retort. The disappearance of oxygen is an indication that combustion must have taken place to an appreciable extent. It is undoubtedly true that air drawn in at the retort mouthpiece is capable of producing the combustion of gas and tar in the ascension pipe. By this means, higher temperatures are attained in the ascension pipe itself, which is, in consequence, converted into a tar-still, and it is beyond the wit of man to unravel the nature of the reactions liable to be taking place therein. The author suggests that one of the main causes of stopped pipes is the introduction of oxygen, and the conversion of the ascension pipe into a tar-still for the manufacture of pitch.

With the introduction of air into the gas during its passage into the ascension pipe there is again an increased volume of gas produced—15,550 cu. ft. per ton—and once again the therm yield is far from poor—viz., of the order of 70 therms per ton. In this case the destructive effect of combustion in the ascension pipe has been partly replaced by the distillation and cracking of tar. Once again it is impossible to determine the loss of true gas therms by this process of combustion in the ascension pipe. That there has been a considerable loss is evident from the curves and models. The outstanding disadvantages which accompany this method of procedure are the disastrous effect upon the quality of tar produced and the additional retort-house cost incurred by reason of stopped pipes. It follows that these disabilities must occur to a similar degree with a retort door or fitting possessing a slight leak, and the little puff of smoke which may be seen issuing from the retort mouthpiece during the first few hours of the carbonising period does not represent the total loss that may be incurred, for with the disappearance of the smoke there will be drawn in air, which is liable to cause combustion of valuable gases in the ascension pipe, with the production of technical difficulties in the form of stopped pipes,

It has been demonstrated that destruction of gaseous therms takes place with a pierced or porous retort or badly fitting door, or, in fact, any unsound fitting on the vacuum side of the retort-house governor, which allows air to be admitted before the gas has cooled down to the temperature of the ignition point of its own easily combustible constituents. Yet, on the other hand, it has been seen that the therm yields of gas under these conditions are not altogether unsatisfactory. It has been shown, however, that the gaseous therm yield, when taken alone, does not represent the efficiency of the process or the degree of conservation practised. This is due to the fact that, whereas the introduction of furnace gases through the coal charge has a beneficial effect on the therm yield, there is always the possibility that the richer gases, produced in the earlier stages of carbonisation, may escape through the holes by which the scouring inert gases enter. It is evident, therefore, that the highest thermal yield in the form of gas is to be obtained by carbonising in the soundest possible retort. Now it is impossible to imagine that even in the very best conducted works all retorts are maintained in a state of first-class repair. Since it has to be assumed from present knowledge of fire-clay materials that retorts must be expected to develop cracks or holes, the best means of obtaining the highest thermal yields from a setting in a bad state of repair will be to operate each retort according to its condition. This will necessitate varying the vacuum maintained during carbonisation to a different degree

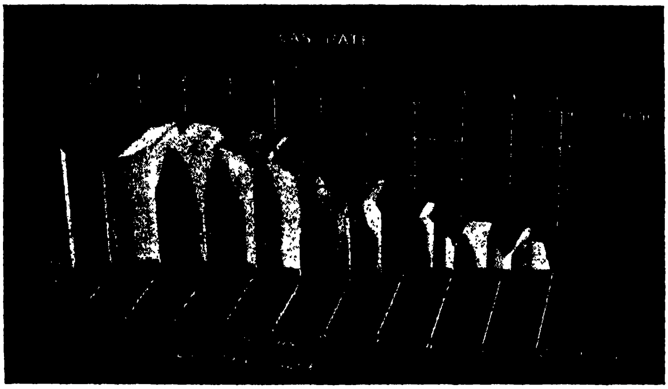


FIG. 14.

in each retort, and the possession of a device to effect this would carry with it many other advantages which need not be analysed at the moment.

Fig. 14 shows how disastrous may be the result, in the case of a pierced retort, of the practice of reducing the vacuum to level gauge when the retort doors of a section are open for discharging and charging. The thermal model, the analyses curves, and analysis model (fig. 15) need little comment.

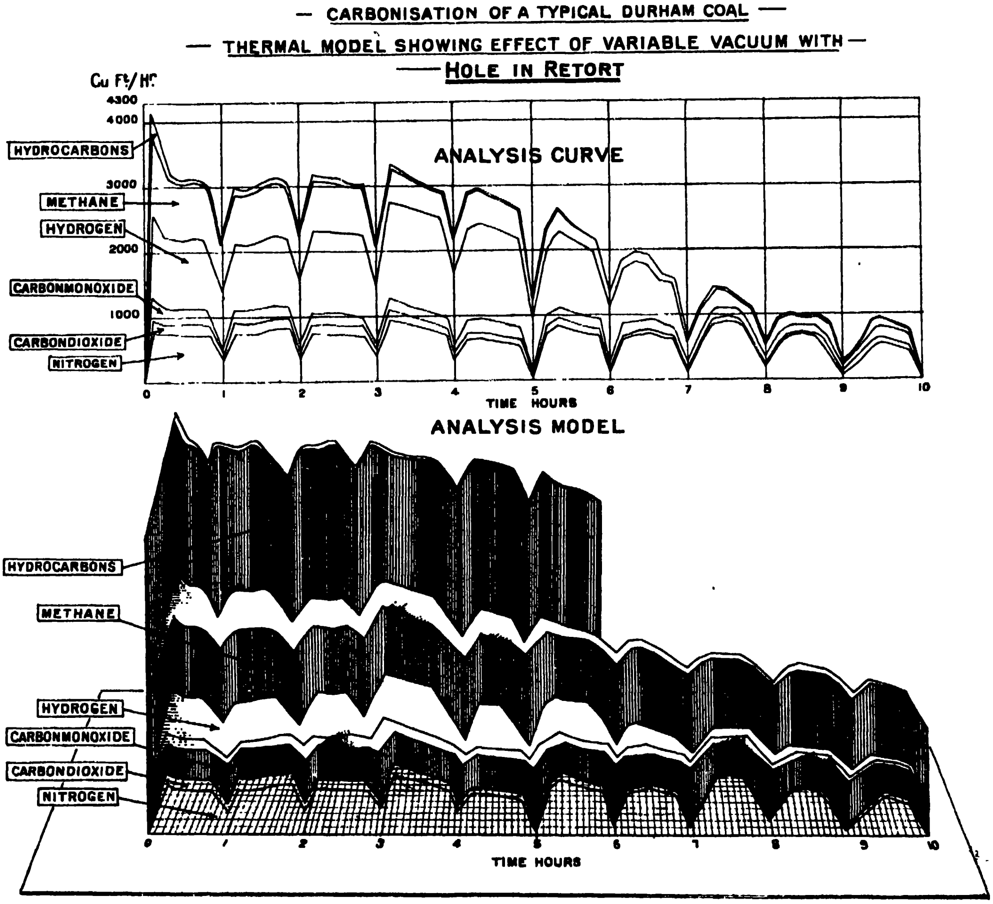

FIG. 15.

At each period of releasing the vacuum a large loss in volume is realised and the curves become almost mountainous. The thermal yield of gas was as high as 74.6 and the calorific value of the gas below 400 B.Th.Us. per cu. ft.

One point to be noted with regard to the thermal models relates to the varying volume of gas made immediately subsequent to closing the retort door, as exemplified by the different heights assumed by all these models. It has been found that the volume of gas produced is determined by the temperature that the retort itself has attained during the interval between discharging and recharging. The temperature of the walls of the retort mounts rapidly after the withdrawal of the charge, due partly to the increased rate of heat transmission which occurs and to the fact that retort carbon is burned by the air entering through the open door. Apart from many other reasons why it is advantageous to close the door as rapidly as possible after recharging the retort, this is given as one which is not usually appreciated.

Finally, it is interesting to attempt to realise how uncontrollable becomes the carbonisation process by allowing the retort-house to fall into disrepair, or by attempting to utilise unsuitable plant and machinery.

The retorts, some of which may be scurfed, while others require scurfing, will present different degrees of porosity, and either loss of gas or the producer gas reaction will take place, according to the length of time the charge has remained in the retort, and the position of the hole in the retort. Many retorts are controlled by one governor, and the conditions under which the retorts are operated must be the same, though retorts in bad condition require to be operated differently from those in good condition. An unequal distribution of heating gas in the setting not only causes certain retorts to be maintained at appreciably different temperatures, but produces in any one retort an unequal heating effect. By no system of control can individual retorts be operated according to their condition, or age, or to the evenness and degree of their heating, or the lie of the retort charge, or the tightness of the retort door, and yet the influence of these factors, not only on the nature of the gas made, but upon the thermal yield of true coal gas, is very appreciable.

As a chemist, the author is not displeased to find chemists well established in the retort-house, and in a well-designed and conducted house they can save large sums of money. They are incapable, however, of serving any useful purpose in a retort-house which manages itself by virtue of its uncontrollable conditions. This picture is perhaps drawn a little forcibly, but it is substantially true, and the retort-house chemist or foreman, or whoever may be responsible for efficiency, obtains the best result circumstances allow. With carbonising conditions only partly under control, the process becomes an art, or a knack, or an acquired additional sense, and the author has seen some fine old artists in the form of retort-house foremen work miracles in the management of "unmanageable" retort-houses. Wonderful pottery was fired by the ancients, fabrics were dyed in a beautiful way by natives with vegetable dyes applied in the crudest manner, and an observant cook may prepare an excellent dinner with half the burners of a gas cooker stopped up with fat and grease, but all these methods are costly and the percentage of failures is high. The carbonisation of coal becomes a science only when the reactions taking place are carefully controlled by the chemist, so as to obtain the most efficient results, and this is possible only when the engineer installs a first-rate retort-house and maintains it in a first-class condition.

NOTES ON BOOKS.

◆

Colour Schemes for the Home and Model Interiors. By Henry W. Frohne and Alice F. and Bettina Jackson. London: J. B Lippincott Company. 25s. net.

There are some fortunate individuals so gifted with an eye for colour that they cannot make a mistake when they set about decorating a room. These, however, are the rare exceptions. Most of us, when we set about the task of home-making, find that, in spite of the best intentions, we have made bad mistakes and condemned ourselves either to live with what displeases us or to incur further expenditure in correcting our errors. For such as these the volume before us will prove a godsend. The authors have stated broadly the more fundamental principles of good design and colour harmony, and while wisely abstaining from any academic exposition of these principles, they have given the lay reader sufficient guidance to enable him to produce a comfortable and harmonious home.

The book is written by Americans and naturally deals largely with American conditions, but that only affects to a very small extent its value for non-American readers. Clever hints are given as to the best ways of treating rooms of ugly or awkward shapes, the choice and disposition of curtains, floor coverings, and the principles which should guide one in selecting furniture. Specimens of rooms furnished according to the authors' taste are shown in a number of excellent photographs, and a word of praise must be added for the very charming and delicately coloured plates giving suggestions for the decoration schemes of various rooms.

RHUBARB IN SZECHWAN.

Rhubarb plants are found throughout the highlands of the Chinese-Tibetan border, but, as in the days of Marco Polo, the best is obtained from the regions of Tangut, which stretch from Sungpan, Szechwan province, to the south-eastern corner of Kansu province. Rhubarb grows among scrub and rocky watercourses at 7,500 ft. to 18,500 ft. altitude. It is, however, also cultivated, but the wild rhubarb is esteemed the best drug. The finest rhubarb, according to the *Chinese Economic Bulletin*, is secured from the species of plant known botanically as *Rheum plamatum, var, tanguticum*, and this is the variety most commonly met with in the extreme northwest of China and the contiguous Tibetan regions. From Tachienlu, a second grade rhubarb is exported in considerable quantities, mainly derived from *Rheum officinale*, although the variety *tanguticum* also occurs sparingly in that neighbourhood. Other species grow in the West, and are used as adulterants. In north-western Hupeh, *Rheum officinale* occurs in the forests, and is also cultivated by the peasants, but the quality of the drug is very poor. The Tangut regions enjoy a dry sunny climate, and here the preparation is a much easier task than in the other districts mentioned. The change of climate probably affects the quality.

Unsightly pieces of rhubarb are occasionally rendered more attractive in appearance by turmeric; the same is true of powdered rhubarb. In testing the quality of the drug, about five grains of rhubarb are placed on white blotting paper with a few drops of chloroform. When the paper surrounding the powder produces a deep yellow stain similar to turmeric, a pinch of powdered borax is added, also a single drop of hydrochloric acid. If the stain is produced by the rhubarb, its colour will not be affected, but if the rhubarb contains turmeric, the colour will change to a distinct red in a few seconds.

The exact production in Szechwan province is unknown, but it is usually estimated at 10,000 to 15,000 piculs a year.

FORESTS AND FORESTRY IN ONTARIO.

In the course of a paper read before the British Association for the Advancement of Science at Toronto, Mr. E. J. Zavitz stated that of Ontario's total land area of approximately 407,262 square miles, 240,000 square miles might be classed as forest land. With a forest region so vast in area and running low in acreage yield, Ontario was confronted with a difficult problem in forest protection and administration.

About one-third of the acreage of this forest was of merchantable character, the remaining being either inaccessible or composed of areas of young growth.

Ontario was in a favourable position from the standpoint of the future development of forest policy, as the greater part of the forest area remained in the Crown, the timber-cutting rights only being leased. Of the forest area, approximately 23,000 square miles was dedicated and set aside as parks and forest reserves, although no real forest management had as yet been introduced.

Ontario's forests provided annual revenue to the State of approximately $3,000,000. The annual value of Ontario's forest products at the place of production totalled something over $100,000,000, with an investment in mills and equipment amounting to over $200,000,000.

WATER-POWERS OF CANADA.*

Canada is particularly fortunate in the nature, extent, and location of her power-producing resources. The water-power resources of Canada are widely distributed and of great extent. They are to be found in every province, and are most abundant in the central provinces, where the absence of native coal makes them of special value. Climate and topography are both favourable to the presence of water-powers on a large scale. The rainfall is abundant, the mountain systems are extensive, and the snow-fields of the Rocky Mountains and the uncounted lakes of the Eastern Plateau form vast natural reservoirs. Water-power is indeed one of the principal natural resources of the Dominion, and its development may, without exaggeration, be termed one of the romances of engineering industry.

The modern water-power industry began in Canada about 1895, and has shown a steady and remarkable growth which promises to be even more rapid in the future than in the past. During the last ten years, while the population increased 22 per cent., the developed water-power increased nearly 100 per cent. and its use in industry 245 per cent. The total water-power throughout the Dominion is estimated at over 18,000,000 horse-power, of which 3,227,414 horse-power is now developed, and 750,000 additional horse-power is under construction.

The capital invested in water-power development, transmission and distribution has grown from $121,000,000 in 1910 to $688,000,000 in 1923, and the opportunities for further investment in such enterprises are numerous and attractive. Natural resources are abundant, labour conditions are stable, agriculture and manufactures are increasing their yield, and new markets are being developed. The conditions in the central station, pulp and paper, mining and other industries, show their dependence upon water-power development.

The greatest part of the undeveloped water-powers of Canada belong to the Crown, either in the right of the Dominions, as in Alberta, Saskatchewan, Manitoba and the Territories, or in that of the provincial governments, as in the other provinces. The Crown grants issued under the various jurisdictions afford security of tenure and reasonable protection to capital, combined with such extent of control as is considered necessary in the public interest.

In some of the provinces developments have been made directly by Government agencies; in others private enterprise is alone responsible for the supply of hydro-electric energy. Each in its own sphere has given beneficial results.

AGRICULTURAL RESEARCH AND FORESTRY IN THE FRENCH ZONE OF MOROCCO.

In the course of his Report on the economic and commercial conditions in the French Zone of Morocco, H.M. Consul at Casablanca points out that the Protectorate is rendering considerable services in this new country by its practical research work. Apart from several stud farms, it has five experimental farms—at Fez for cereals; near Mazagan, in "sahel" soil, for pasturage plantations and shrubs and trees; at Marrakesh to study irrigation requirements of different cereals and trees: at Casablanca for vineyards, market gardens and pig breeding; and at Oudjda to study the breeding of mules.

---

* Extract of a paper read before the British Association for the Advancement of Science, at Toronto, by Mr. J. B. Challies, Director of the Water Power and Reclamation Service.

At Rabat, Meknes, and Marrakesh experimental gardens exist for growing flowers, fruit, vegetables and trees, and at Sefrou a silk-worm farm is carrying on investigations. Every effort is made to bring all results to the notice of farmers.

Forests.—The forests of Morocco are now under the enlightened supervision of the Forestry Service, and their area is already on the increase. For centuries, however, the forests were wantonly destroyed. The area under the various trees is estimated as follows:—

	Acreage.
Argan tree (arar wood) ..	1,000,000
Thuya (conifer)	750,000
Cork, oak	650,000
Oak, green	500,000
Juniper, fir trees, etc.	500,000
Cedar (alone or with other trees)	400,000
	3,800,000

The cork and cedar are alone industrially exploited at present.

GENERAL NOTE.

Revival of Manaar (Ceylon) Pearl Fishery.—The Government of Ceylon has decided to revive the pearl fisheries near the port of Manaar on the north-west coast of Ceylon, and operations will probably be started in the autumn of this year. This is the first time, writes the United States Consul at Colombo, that pearl fishing has been attempted in the locality since 1908, when an unsuccessful expedition in the hands of a private fishing company was undertaken. It is believed that the fishery should be successful as the number of oysters is said to be very large and such pearls as have been procured are of fine quality.

Artificial Silk Industry in France.—Artificial silk manufacture in France has experienced a very rapid development in recent years. As early as 1911, when the production of artificial silk in the world was estimated at 5,000,000 kilos, France contributed more than 1,000,000 of the total. Since that time, however, writes the United States Commercial Attaché at Paris, the manufacture of this product has received a great impulse in other countries. Nevertheless, in spite of periodic fears that local manufacture may outrun its market, the French industry has continued to prosper, due in a large degree to the fact that natural silks have not increased greatly in supply, while the demand for silk textiles has constantly grown.

Australian Motor Trade.—A Melbourne correspondent, writing in the *Times Trade & Engineering Supplement*, of 28th June, says:—"The cheap American cars find favour in this country. The market is flooded with them, while commercial cars of similar origin are increasing in numbers to a surprising degree. During the past 12 months the number of motor chassis imported into the Commonwealth was 56,157. The value of these imports was £7,442,000. America contributed 27,765 chassis, valued at £3,743,950. Next in order was Canada, with 23,483 (£2,056,818), while the United Kingdom was third on the list with 2,007 chassis, worth £905,162. Imports from France numbered 1,189 valued at £265,226, and from Italy there were 1,281 cars of a value of £384,693. Imports from other countries were negligible, although of late German cars have reappeared on the market." With regard to the Australian motor-body building industry statistics show that the car importers have given a great fillip to the local trade. Chassis importers purchased from Australian body-builders 46,851 bodies, valued at approximately £3,279,570. During the year there were 13,941 bodies imported from America, 1,332 from Canada, 625 from the United Kingdom, 154 from France, and 148 from Italy. In April, 2,638 new motor vehicles were registered in Victoria alone.

Aerial Photography and Surveying.—In a paper read before the British Association for the Advancement of Science, at Toronto, Mr. A. M. Narraway, Controller of Surveys, stated that during the past two seasons considerable experimental work had been carried on in Canada in the utilisation of aerial photography for mapping purposes. The results obtained had enabled the Topographical Survey of Canada to apply these views in a practical and economical manner to supplement ground surveys. Marked progress had been made in mapping by oblique aerial photographs the important mineralised areas in Northern Manitoba and the intricate system of waterways in that district, and in obtaining information relative to forest cover by this means. Aerial photographs were also being used extensively in land classification, revision, and soil surveys.

The Severn Barrage Scheme.—Preliminary investigations to ascertain the feasibility of the scheme for using the tidal power of the Severn in the production of electrical power by the erection of a barrage across the river are to be proceeded with at once. The work has been entrusted to the Department of Scientific and Industrial Research and will be supervised and directed by a committee presided over by Mr. G. S. Albright, C.B.E., while Sir Maurice Fitzmaurice, C.M.G., F.R.S., and Sir John Purser Griffith, M.A.I., M.Inst.C.E., have been asked to submit a joint report before the end of this year as to the possibility of constructing a barrage on one or more of the sites suggested, on the assumption that safe foundations exist. The data provided by the geological and hydrographical investigations will be placed at the disposal of Sir M. Fitzmaurice and Sir J. P. Griffith.

CANTOR LECTURES.

A STUDY OF THE DESTRUCTIVE DISTILLATION OF COAL.

By Edward Victor Evans, O.B.E., F.I.C.,
Chief Chemist and Products Manager, South Metropolitan Gas Company

Lecture II.—*Delivered March 3rd,* 1924.

In the first lecture it was demonstrated that to determine only the gaseous thermal yield in the carbonising process was useless from the point of view of computing the efficiency of that process. It was shown that, though high gaseous thermal yields could be obtained with a hole in the retort or a leak in the mouthpiece, there was always a loss of true coal gas, the extra gas therms being made indiscriminately at the expense of another therm-containing constituent of the coal. It followed that the most economical results were to be attained by carbonising in a tight retort, and, if dilution were needed, by admitting a diluent gas under careful control.

Experience has shown that, if a system of very tight retorts is operated at a combustion chamber temperature of 1300°/1350° C. and maintained under a reasonable vacuum of $\frac{3}{10}''$ water gauge, the gas manufactured possesses the characteristics shown under A in Fig. 16. Such a gas contains so small a percentage of inert constituents and is consequently of so low a density and high calorific value that it is unsuitable for use in the inverted bunsen burner. There are many methods of adjusting the composition of this gas, as for example, by adding under control water gas, producer gas or waste gases. It was imagined that the least economic method would be to reduce the calorific value by raising the temperature of distillation, whereby undue degradation of the gas itself might result. It was decided, therefore, in the case in point, to add waste gases to the crude coal gas prior to purification. The effect on the calorific value and specific gravity of the gas of adding waste gases—*i.e.* inert constituents—is shown in Fig. 16. It was desired to add a proportion of waste gases sufficient to remove point A on the curve to B in order to produce a gas of 572 B.Th.Us. per cu. ft. which, upon subsequent admission of air to the purifiers, would be reduced to the desired calorific value, viz., 561 B.Th.Us. per cu. ft. The installation used for this purpose is shown in Fig. 17. A small exhauster drives the required volume of waste gases through the large meters shown in the illustration, and the quantity is very carefully controlled by reference to the recorded calorific value of the gas before and after treatment. Typical calorific value curves are shown in Fig. 18; the two upper charts indicate the nature of the gas made in the retort houses before adjustment and the lower chart the nature of the gas after dilution. It will be seen that a remarkably constant gas, from the point of view of calorific value, is delivered into the holders.

The great advantage of such an installation lies in the constancy of the thermal value of the gas and the close approximation to the declared calorific value which may be attained. This is not only of advantage to the consumer, but also to the gas manufacturer, who is frequently forced to supply a gas of calorific value materially higher than that declared, in order to be assured that the minimum calorific value never approaches the 6% penalty limit. The net result of operating the installation above described is to produce without marked degradation of gas or tar a 560 B.Th.Us. gas of very constant physical characteristics. No apparent increase in gaseous thermal yield has been observed and this is attributable to the fact that, when higher temperatures are maintained for the purpose of decomposing the gas down to the required standard, a certain degree of tar cracking takes place.

Fig 16.

This does not occur with the adjustment plant in operation and in consequence a higher yield of tar is obtained. Whether or not it is advantageous to crack tar into gas is a question of economics which will receive consideration later, but the point to be made at this stage is that, whereas it has been shown in the first lecture that the thermal yield of gas alone is of no use in computing the efficiency of the process, the conclusion is now arrived at that, as the therms of tar and gas are interchangeable, no true appreciation of results may be obtained unless the thermal value of tar be also taken into account. In controlling the carbonising process, it is necessary, therefore, to determine not only the yield of gas therms, but also that of tar therms, and it is convenient to class these together under the heading of "volatile therms." Results of working may thus be expressed as follows: There has been obtained a total yield of 90 volatile therms of which 73 are in the form of gas.

In this lecture it is proposed to deal solely with the very close relationship existing between gas and tar, as the author does not think this subject has in the past received sufficient attention from the gas industry.

The introduction of the therm system has rendered practically useless the investigations of men in the gas industry who have expressed their results in terms of cubic feet of gas of a certain illuminating power per ton of coal. This is to be regretted, but it is the result of circumstances. The absence of data relating to the calorific value of the tar recovered is not so serious an omission since if the yield of tar be known an average figure may be taken for the purpose of ascertaining a very approximate tar thermal

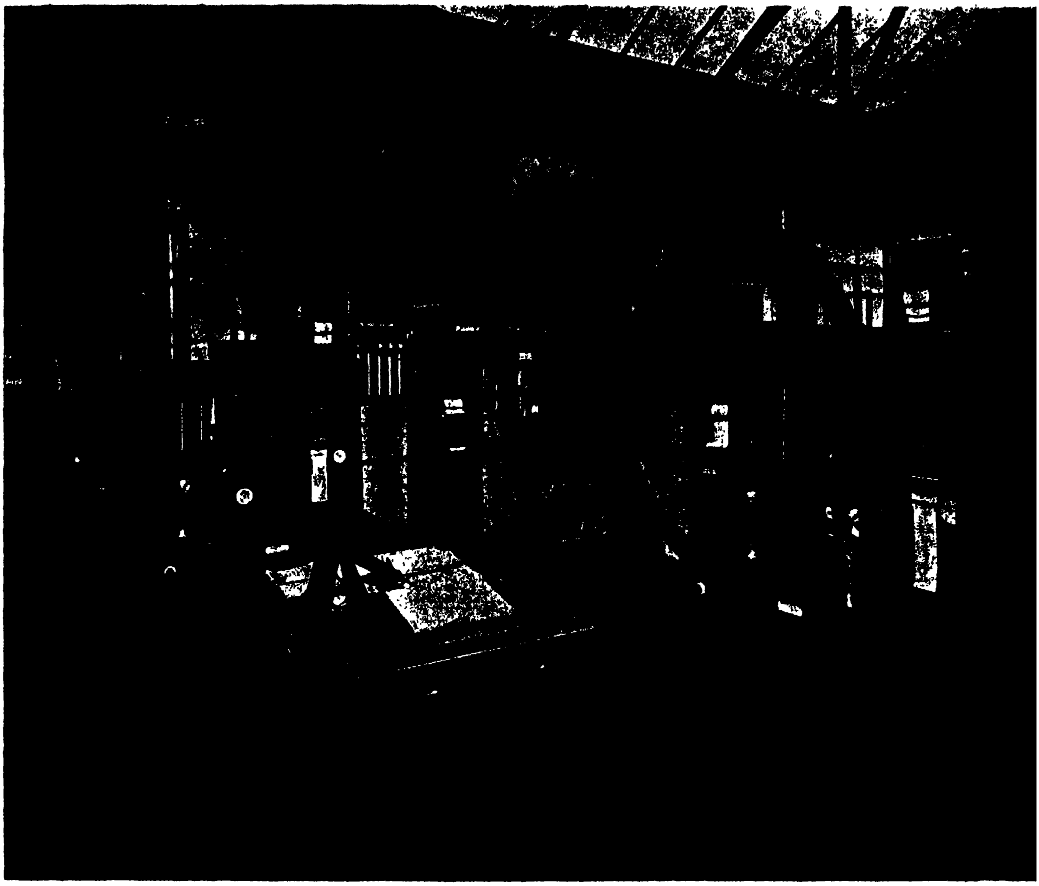

FIG. 17.

yield, but the fact that investigators have failed to note the volume and nature of tar recovered, when studying the effect of varying conditions upon the carbonisation process, shows a lack of appreciation of the part that may be played by tar. The results of sound investigations in the gas industry to be of any value must be expressed upon the basis of the thermal yield of each of the products, gas, tar, and coke, but many of the reports, dissertations and claims appearing in the gas literature of to-day are entirely misleading, as they are made by investigators who have failed to appreciate the thermal interrelation between the three products derived from the carbonisation of coal. While one Works is able to obtain 80 therms of a gas which is obviously not true coal gas, another obtains a high yield of a gas the analysis of which indicates that it must have left behind pitch instead of tar. No data, however, are given concerning the yield and nature of the resulting tar, so that it is impossible to obtain any accurate conception of the efficiency of the carbonisation process. If one is looking for high gaseous thermal yields and if the whole of the volatile matter is expelled from the coke, then there is a certain limit beyond which gas must be manufactured at the expense either of coke or tar, and the investigator who, in studying the effect of certain carbonising conditions, overlooks this, paints only half a picture and obtains results which bring little enlightenment to the gas industry. The importance of considering the yield of volatile therms will be apparent when it has been demonstrated how this yield and the proportion of gas therms to tar therms are affected by the nature of the distillation process.

The results of an investigation carried out to determine the effect of the rate at which the coal charge is heated upon the relation between the yields of gas therms and tar therms will now be examined. The results

of this investigation are embodied in Table A. These tests have been carried out upon only 100 grammes of coal, but to secure uniformity, a large sample has been finely ground and small briquettes have been made of the mixture (under pressure without binding material) for the purpose of obtaining homogeneous samples. The author is well aware that carbonising trials on such a small scale are likely to be misleading. These results in so far as they relate to the points in question, are generally in accord with Works practice and it is on this account that they may be considered to possess technical interest.

The coal used in these small scale carbonising trials was a typical Durham coal, the analysis of which is shown in the next column. The apparatus used consisted of a silica retort 2" in diameter and 24" in length, packed at its closed end with asbestos. This retort was charged with five cylindrical briquettes placed end to end within the central portion of the retort, the total combined length of the briquettes being approximately 7". A pyrometer was fitted to the retort and the latter was either plunged into a fully heated furnace or introduced into a cold one which was gradually heated to the required temperature over a definite period; the final temperature attained within the retort was the same in all cases. A sectional view of the furnace is shown in Fig. 19, while Fig. 20 is a photograph of the whole apparatus. For the purpose of this lecture and until a detailed description of the work is published, the author wishes it to be assumed that the construction of the apparatus, and its manipulation, together with weighing and analytical

FURNACE USED IN THE CARBONIZATION OF BRIQUETTED COAL AT VARYING RATES

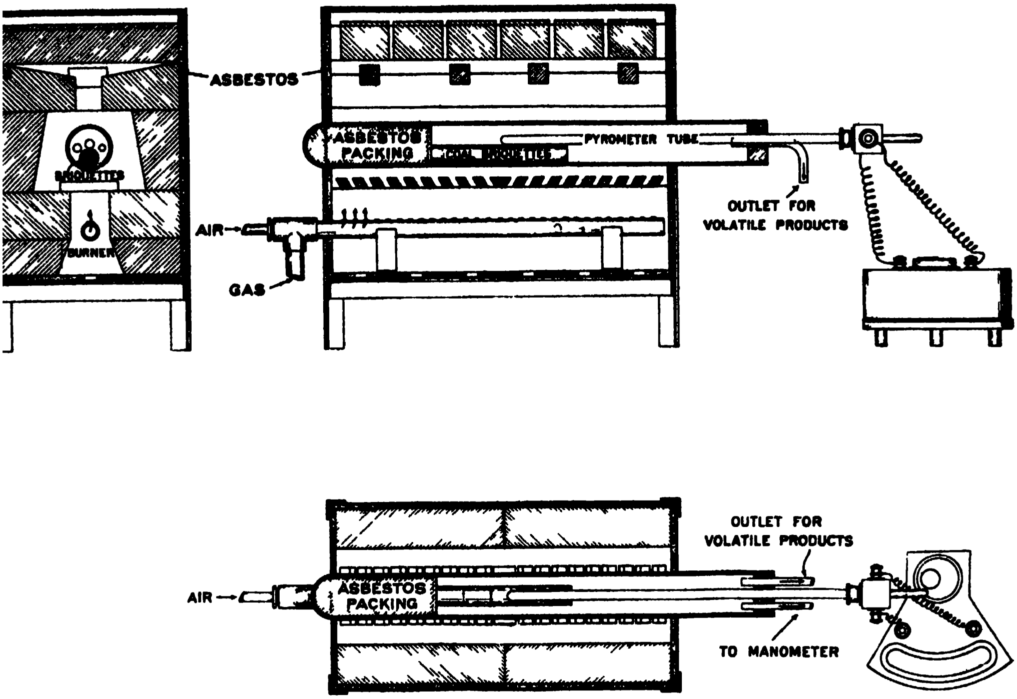

FIG 19

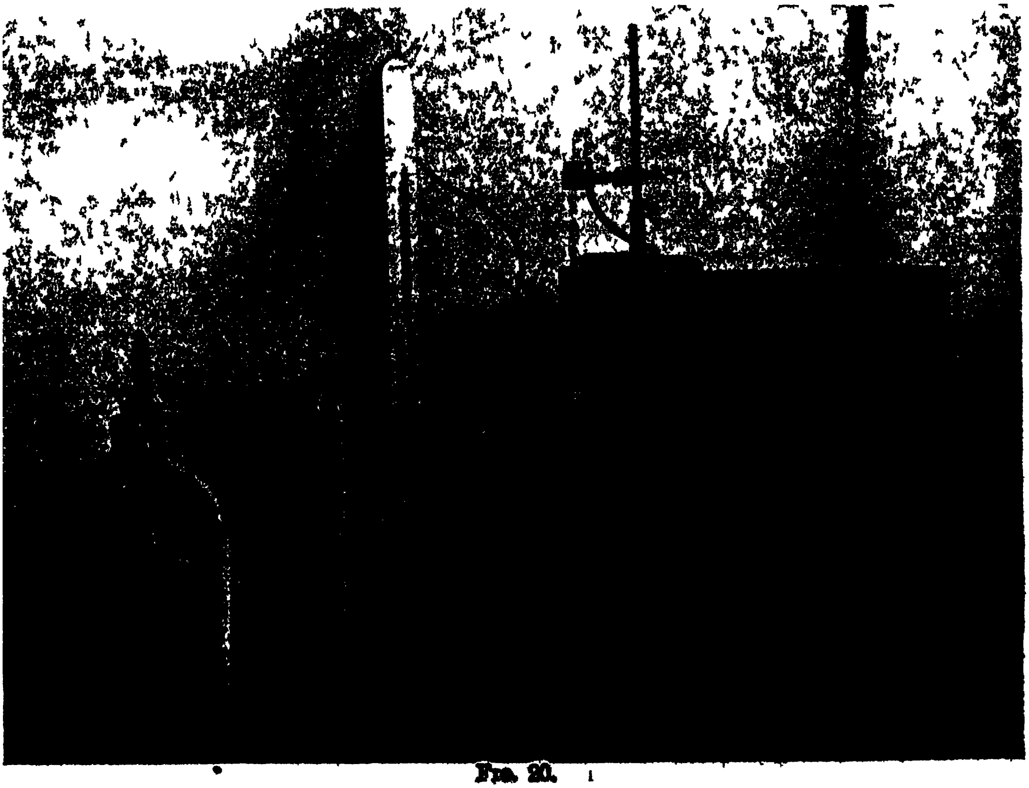

FIG. 20.

operations, were carried out in an approved manner.

It will be observed from Table A that the final temperature attained in this series of carbonisations was 1000°C., but that the time taken to attain this temperature varied from 18 minutes to 13 hours. In the first experiment the retort was placed in a furnace already heated to 1000°C. In this respect this experiment differed from the remaining carbonisations, in which the furnace was gradually heated up until a temperature of 1000°C. was attained in the retort within the required time. An important point to be made is that, however quickly the final temperature, as observed by the pyrometer, was reached, the carbonising process was always practically finished at this stage, and though each test was extended for some time after the final temperature was attained, the quantity of the products distilled was found to be small. In computing the results of all experiments, a correction has been made for the residual gas in the retort and other apparatus at the end of the experiment by adding 1.5 therms per ton to the yield of therms calculated from the volume of gas actually collected and its calorific value. This figure of 1·5 was based upon an experimental determination of the approximate composition and volume of the residual gas.

The following points will be noticed from an examination of the table :—

(1) The yield by weight and the total thermal content of the coke increase slightly as the rate of heating decreases.

(2) The tar by weight and thermal content increases rapidly to a certain maximum and then falls off.

(3) The thermal yield of gas falls rapidly as the rate of heating decreases, until a certain limit is reached beyond which there is no further reduction.

(4) The carbon and pitch (which is the material other than coke left in the retort after the test) falls to a minimum both in weight and thermal content, but again rises with exceedingly slow carbonisation.

It will now be of interest to study the relationship existing between gas therms and tar therms and the effect of the rate of carbonisation upon the total number of volatile therms produced. The two most important observations to be made in this connection are :—

(1) The total volatile therms computed by adding together tar therms and gas therms, show a gradual decrease as the rate of carbonisation becomes slower, there being a marked decrease in the case of exceedingly slow carbonisation. There is thus a lower, rather than a higher, yield of volatile therms resulting from the slow and careful carbonisation of the charge.

(2) Although the yield of total volatile therms falls but gradually with a reduction in the rate of carbonisation, the ratio of gas therms to tar therms undergoes considerable variation. It will be observed that whereas rapid carbonisation favours the production of gas, slow carbonisation up to a point has the effect of preserving tar yields.

As the first of these observations appeared to be contrary to preconceived ideas of carbonisation, it was proposed to carry out the carbonisation in two stages, for the purpose of ascertaining whether this more careful method of carbonisation would still give a low yield of volatile therms. Table B shows the results thus obtained.

In these tests the same type of coal and the same apparatus were used as in the first series of carbonisations. Carbonisation was, however, effected in two stages, a temperature of 525°C. being attained in the first stage. This temperature was maintained until no further volatile matter was expelled and the residue was then heated up to 1000°C. to complete carbonisation. The preliminary temperature of 525°C. as well as the final temperature of 1000°C. was attained in varying times in the three experiments. From the results it is obvious that this two-stage distillation process is a more careful—*i.e.* a less drastic—carbonising process. It is less drastic in that there is obtained an abnormally high yield of tar, very little carbon and pitch and a yield of gas therms which is quite poor when considered in the light of to-day's working result. It will be observed that the percentage of unsaturated hydrocarbons in the final gas is low. The total yield of volatile products is, however, of the same order as the yields obtained in the moderately slow carbonisations of the first series of experiments.

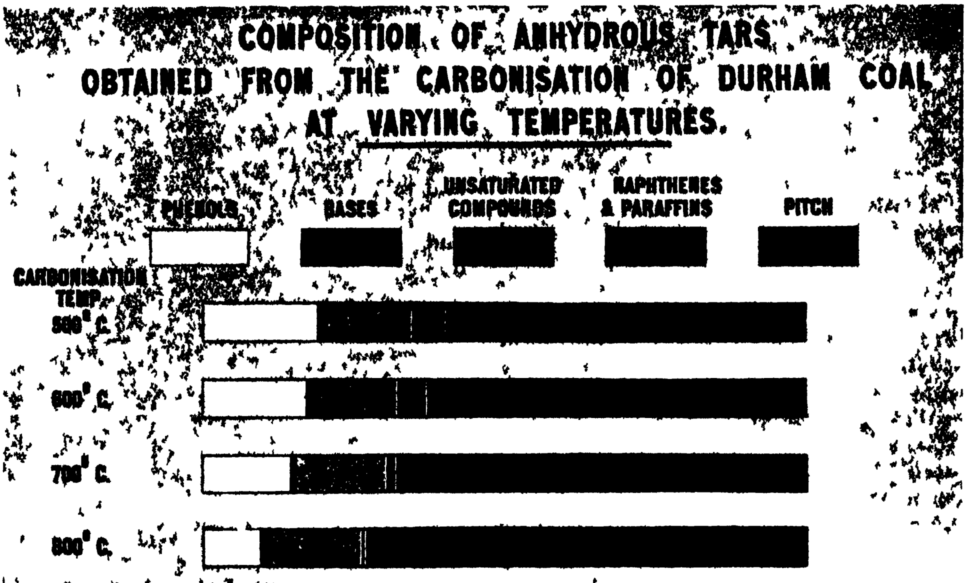
It is a remarkable fact that under conditions of careful and slow heating the yield of volatile therms obtained should be so low, but this observation forms the basis of important conclusions to be developed subsequently. The first hypothesis which was

suggested to explain the results obtained was that some molecular rearrangement of the coal substance itself took place at a moderately low temperature, before true carbonisation commenced, and that on this account the coal became less suitable for gas manufacture. The author is, however, now convinced that a very much simpler explanation lies in the suggestion that when the coal is very slowly distilled there occurs simultaneously a fractional distillation of the tar, with the consequent formation of pitch. An observation which tends to confirm this hypothesis is that the tar obtained is a limpid brown liquid containing a very small proportion of pitch and practically no free carbon and when the carbonisation process is very protracted, it is comparatively small in quantity. Further, such a hypothesis would account for the considerably augmented coke yield, as well as for the increase in the quantity of pitch and carbon found in the retort, which otherwise would be inexplicable after such special precautions had been taken to carry out a very careful distillation of the coal. There is much more evidence to support this hypothesis which will be presented at a later stage.

The second important conclusion which resulted from a study of these experiments will now be considered—*i.e.*, that the more rapid the carbonisation the greater the thermal yield of gas. It is evident that the additional gas produced during rapid carbonisation results principally from the cracking of tar within the retort. This decomposition of the tar is at its maximum in the case of the most rapid heating, as may be seen also from an examination of the nature of the gas produced. The most outstanding characteristic of the gas is the high proportion of unsaturated hydrocarbons—a fact which points to the judicious decomposition of tar. It is of interest to note, however, that tar cracking—to the extent to which it is practised in these experiments—appears to proceed without any appreciable loss in therms, for it will be seen from Table B that, for all practical purposes, it may be said that the therms lost from the tar are approximately recovered in the gas. These results dispose of the objection to horizontal retort working which has been put forward by those interested in promoting a slow and more careful method of distillation. This objection is founded upon a belief, which the author knows to be mistaken, that the rapid heating of coal is very wasteful of thermal energy.

The outstanding conclusion to be drawn from this work is that there is a tendency for the highest volatile therm yield to be obtained by practising the most rapid heating possible, and, while such a condition is certainly conducive to high gaseous therm yields, slower and more careful distillation is a tar conserving process and exceedingly slow distillation a coke conserving one. Beyond this, the work is only of academic interest, as the conditions of these experiments are not directly comparable with large scale working of to-day. The excellent yields of volatile therms obtained in these experiments are explicable and have formed the basis of further investigations of the principles of obtaining enhanced yields of volatile therms.

Returning to the important question of the extent to which tar may be profitably cracked into gas, certain chemical aspects of the mechanism of tar cracking should be presented. By this means it is possible to demonstrate that there is a certain limit to the quantity of gas which may be produced from tar, the over-stepping of which limit results in the deterioration of the tar to such an extent that the process becomes untenable from many points of view. It is almost unnecessary to explain that in the production of gas at the expense of tar—an operation which is proceeding to a varying extent at all stages of coal distillation—it is not a certain proportion of the tar which is changed into gas, leaving the remainder unchanged, but the character of all the tar is entirely altered, as regards both its physical properties and chemical constitution. The brown limpid fluid obtained under conditions of slow heating is replaced under the conditions of rapid heating and high temperatures by a thick black tar, which becomes more and more viscous with increasing decomposition. These points are very well developed in Fig. 21, which shows the analyses of tars obtained from the carbonisation of a Durham coal at increasing temperatures. It is apparent that with increasing temperatures the naphthenes, paraffins and phenols gradually disappear, while the pitch content is appreciably augmented. Another point of considerable interest, which may be seen from the table in that diagram, is the degree of decomposition which has taken place in the pitch as exemplified by its free carbon content, which is 8.6% in 500°C. tar and as much as 36.1% in 800°C. tar.



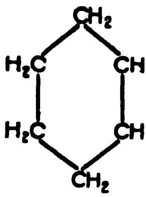
CHARACTERISTICS OF PITCH

CARBONISATION TEMPERATURE °C	FREE CARBON %	SOFTENING POINT °C
500	8·6	30·0
600	12·8	48·1
700	16·5	72·2
800	36·1	97·0

Fig 21.

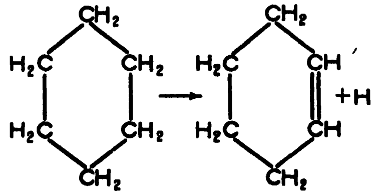
The tar obtained from a low temperature distillation may now be regarded as primary and that from a high temperature distillation as secondary Considerable work is being carried out by investigators at the present moment in connexion with the constitution of these primary tars, and some of the work is leading to such interesting conclusions and would form such a delightful subject matter for lectures, that the author has almost been tempted to incorporate some of it in the present series There is, however, little satisfaction in presenting the work of others and it is suggested that those who are interested should make themselves acquainted with the work of these investigators

The most important class of compounds present in primary tar consists, as first shown by Pictet and his collaborators, of hydrocarbons of the closed ring type similar to those found in petroleum. They may be either fully saturated, as cyclohexane (C_6H_{12}), or only partly saturated, as cyclo hexene (C_6H_{10}), and in order to attempt to trace the mechanism of tar cracking it is proposed to consider in detail the effect of heat upon these two hydrocarbons which may be regarded as typical of other members of the same series The cracking of cyclo hexane forms a very interesting picture of the complicated nature of the multitudinous reactions which take place in the thermal decomposition of a primary tar Complex though the reactions are, they are not so complex as in the case of the decomposition of phenols by heat, for cyclohexane only contains atoms of carbon and hydrogen in the molecule, while the phenols possess also one or more oxygen atoms In the case of cyclohexane, the six carbon atoms in the molecule are linked together in the form of a ring, each carbon atom being attached to two other carbon atoms and two hydrogen atoms It is hexa hydrobenzene, C_6H_{12}

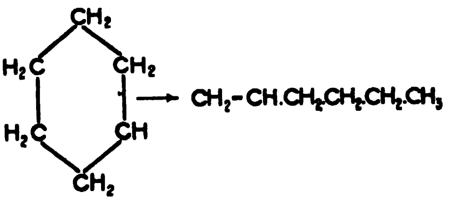


This is usually regarded as a most stable grouping and, in fact, cyclohexane is found to be specially resistant to attack by most chemical reagents. Resistant though it may be to chemical attack, the molecule becomes very unstable at high temperatures, and from this one chemical compound there may originate innumerable compounds, solid, liquid and gaseous. The thermal decomposition of cyclohexane has been studied by several workers (notably by D. T. Jones) and a detailed study has also been made by the author of the liquid and gaseous products of decomposition. This experimental work has formed the basis of a diagram representing the course of decomposition of this hydrocarbon; though some of the reactions indicated may be hypothetical, they are based as far as possible on facts supported by experimental evidence. The object of presenting this imaginative picture is to allow some small appreciation of the innumerable reactions likely to take place in a retort at any one moment.

A large number of the possible reactions which may be conceived to take place in the decomposition of cyclohexane by heat are grouped together in Fig. 22. The decomposition appears to commence either with the elimination of hydrogen, forming the compound cyclohexene, or by direct fission of the ring, when molecular rearrangement will take place resulting in the formation of an open chain hydrocarbon of the unsaturated type, as for example, the olefine n. hexylene.



CYCLOHEXENE.



(*A kinematograph film showing the decomposition of cyclohexane to cyclohexene and to n.hexylene was thrown on the screen*).

The two reactions proceed simultaneously, and probably with similar velocities. The two products of decomposition, n.hexylene and cyclohexene, may undergo further decomposition on heating. In the first place, the possible course of the decomposition ot the n.hexylene is considered. Using the conception of ($CH_2=$) residues originated by Prof. Bone, it may be imagined that this hypothetical group becomes separated from the rest of the molecule by breaking of the double bond—a special point of weakness in the molecular structure—and that the remaining portion then undergoes rearrangement with the formation of the lower olefine amylene

$$\begin{gathered} CH_2{=}CH.CH_2.CH_2.CH_2.CH_3. \\ \rightarrow CH_2{=}CH.CH_2.CH_2.CH_3+(CH_2{=} \\ \text{Amylene.} \end{gathered}$$

(*This reaction was illustrated by a film.*)

Amylene itself may similarly be decomposed with the formation of butylene; and this in turn may give rise to propylene and then to ethylene. Ethylene may finally decompose into two ($CH_2=$) groups.

$$\begin{gathered} CH_2{=}CH.CH_2.CH_2.CH_3 \\ \rightarrow CH_2{=}CH.CH_2.CH_3 \quad +(CH_2{=}) \\ \text{Butylene} \end{gathered}$$

$$\begin{gathered} CH_2{=}CH.CH_2.CH_3. \\ \rightarrow CH_2{=}CH.CH_3 \qquad +(CH_2{=}) \\ \text{Propylene} \end{gathered}$$

$$\begin{gathered} CH_2{=}CH.CH_3 \\ \rightarrow CH_2{=}CH_2 \qquad +(CH_2{=}) \\ \text{Ethylene} \end{gathered}$$

$$\begin{gathered} CH_2{=}CH_2 \\ \rightarrow (CH_2{=}) \qquad +(CH_2{=}) \end{gathered}$$

It should be pointed out at this stage that these ($CH_2=$) residues would be too unstable to exist as such; they would necessarily be very reactive and become involved in other reactions which will be mentioned later. They are, however, especially useful, as Bone has previously shown, in constructing a picture of the mechanism of hydrocarbon decomposition.

Returning to cyclohexene—the primary product in the alternative method of decomposition of the original cyclohexane—this

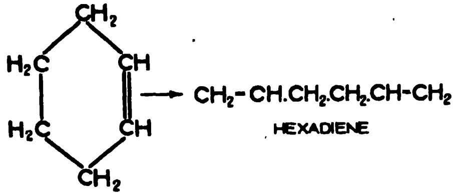
compound cannot resist further decomposition, owing to the presence of the double bond. The major portion, through fissure of the ring at the double bond and rearrangement of the molecule, is converted to open chain unsaturated compounds. The initial product is probably the diolefine hexadiene, and this may be expected to undergo further decomposition, splitting off ($CH_2=$) residues, and giving rise in turn to butadiene and finally acetylene.

(*A film depicting the decomposition of cyclohexene to hexadiene was shown.*)



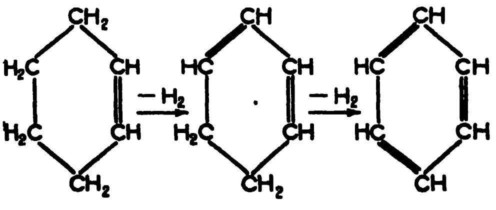
$$CH_2=CH.CH_2.CH_2.CH=CH_2$$
$$\rightarrow (CH_2=)+CH_2=CH.CH=CH_2+(CH_2=)$$
Butadiene.

$$CH_2=CH.CH=CH_2$$
$$\rightarrow (CH_2=)+CH\equiv CH+(CH_2=)$$
Acetylene.

The acetylene may then break down either to the hypothetical ($CH\equiv$) residues or finally to carbon and hydrogen.

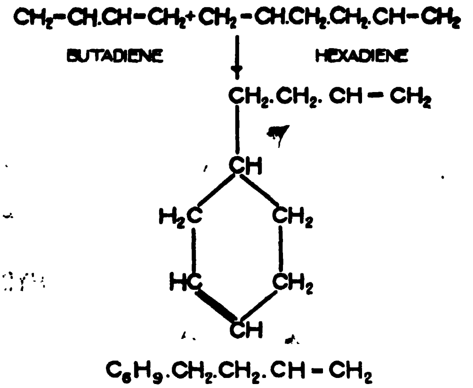
$$CH\equiv CH\rightarrow (CH\equiv)+(CH\equiv)$$
$$CH\equiv CH\rightarrow 2C+H_2$$

A smaller portion of the cyclohexene undergoes loss of hydrogen, resulting ultimately in the formation of benzene. Dihydrobenzene possibly represents a transition stage.



CYCLOHEXENE. DIHYDROBENZENE. BENZENE.

Simultaneously with the other reactions already described, it would appear that some polymerisation and condensation of the unsaturated molecules take place, resulting in the formation of high boiling point unsaturated bodies and aromatic compounds. For example, it is possible to conceive that butadiene and hexadiene may unite to produce tetrahydrophenylbutylene,



$C_6H_9.CH_2.CH_2.CH-CH_2$

TETRAHYDROPHENYLBUTYLENE

which on dehydrogenation may give phenylbutylene

$$C_6H_9.CH_2.CH_2.CH=CH_2\rightarrow$$
$$C_6H_5.CH_2.CH_2.CH=CH_2+2H_2$$
Phenylbutylene.

This compound is well known to be capable of condensing to naphthalene, with the elimination of hydrogen.

$$C_6H_5.CH_2.CH_2.CH=CH_2\rightarrow C_{10}H_8+2H_2.$$

(*A further film showed the formation of naphthalene from butadiene and hexadiene.*)

Before leaving the olefines already referred to, it must be pointed out that these may be hydrogenated to paraffins. A glance at Fig. 22 (in which the hydrogen evolved or absorbed in the various reactions is indicated by dotted lines) will show that there is always present for this purpose sufficient hydrogen produced during the reactions of decomposition. In this way, hexylene may be converted to hexane, and similarly, pentane, butane, propane and ethane may be formed from the corresponding unsaturated hydrocarbons.

$$CH_3.CH_2.CH_2.CH_2.CH=CH_2+H_2$$
Hexylene.
$$\rightarrow CH_3.CH_2.CH_2.CH_2.CH_2.CH_3$$
Hexane.

A reverse change may, however, take place, resulting in the formation of methane and an olefine containing one carbon atom less than the original paraffin. For example, hexane may give rise to amylene and methane.

$$CH_3.CH_2.CH_2.CH_2.CH_2.CH_3$$
$$\rightarrow CH_2=CH.CH_2.CH_2.CH_3+CH_4$$
Amylene. Methane.

The hypothetical ($CH\equiv$) and ($CH_2=$) residues which have been assumed to be produced at various stages of the decomposition, together with a considerable quantity of hydrogen, may undergo interaction or decomposition, with the formation of compounds such as the following :—

(*a*) Methane
$(CH_2=)+H_2 \longrightarrow CH_4$
(*b*) Ethylene
$(CH_2=)+(CH_2=) \longrightarrow CH_2=CH_2$
(*c*) Acetylene
$(CH\equiv)+(CH\equiv) \longrightarrow CH\equiv CH$
(*d*) Benzene
$6(CH\equiv)$ or $3\ CH\equiv CH \longrightarrow C_6H_6$
(*e*) Naphthalene
$C_6H_6+ \begin{matrix} 4(CH\equiv) \\ \text{or} \\ 2CH\equiv CH \end{matrix} \longrightarrow C_{10}H_8+H_2$
(*f*) Carbon and Hydrogen
$(CH_2=) \longrightarrow C+H_2$

portions of free carbon and gas increase with the temperature, while the liquid decomposition products become more aromatic in character. The insignificant amount of benzene produced calls for attention. When the temperature is sufficiently high, complete degradation to carbon and hydrogen may take place. From this picture it is evident that a whole series of both analytical and synthetical reactions are in progress during the decomposition of cyclohexane by heat. When it is realised that, in the first place, cyclohexane is not nearly so complex as most of the other constituents of primary tar, and, secondly, that it is only one of the innumerable compounds present in that tar, no apology will be required from the chemist for his inability to gain anything but the haziest notion of what is taking place in the retort.

The relative proportions in which these various decomposition products are present will be considerably influenced by the temperature at which the cracking takes place. The accompanying diagram (Fig. 23) shows approximately the relative proportions of the important products formed at three different temperatures, 650°, 700° and 750°C. It will be noted that the pro-

Our experiments, though perhaps indicating a slightly different interpretation of the mechanism of cracking of cyclohexane from that suggested by other investigators lead to the same general conclusions :—

(1) Hydrocarbons of the cyclohexane and cyclohexene type are the main gas

yielding constituents of primary tar. The gas resulting from their decomposition is rich in unsaturated compounds, together with ethane and methane, and is consequently of high calorific value.

(2) The higher aromatic compounds, such as naphthalene, anthracene, etc., are formed to an appreciable extent by the polymerisation and condensation of the unsaturated compounds present in the gaseous decomposition products.

(3) Direct dehydrogenation, with the formation of benzene and its homologues takes place only to a very small extent, insufficient to account for the quantity of these compounds present in high temperature tar.

It will have been seen that cyclohexane lends itself admirably to the cracking process and it is probable that the gas industry depends greatly upon the cracking of hydrocarbons of this type for the production of gas sufficiently rich to allow of the subsequent admixture of water gas without unduly lowering the calorific value below that requisite for economic distribution. It is probable that such hydrocarbons as cyclohexane are selectively cracked in the decomposition of primary tar, leaving a residue of secondary tar which is less suitable for further cracking. This question of the cracking of primary and secondary tars has been studied in a series of experiments in which high and low temperature tars have been cracked in a somewhat artificial way in the laboratory. In these experiments the tars have been heated to various temperatures and their vapours cracked over heated coke in the presence of nitrogen or coal gas. Though the results of these experiments are presented, it is beyond the wit of man to interpret the results obtained in terms of the actual chemical reactions which have taken place.

FURNACE USED IN TAR CRACKING EXPERIMENTS.

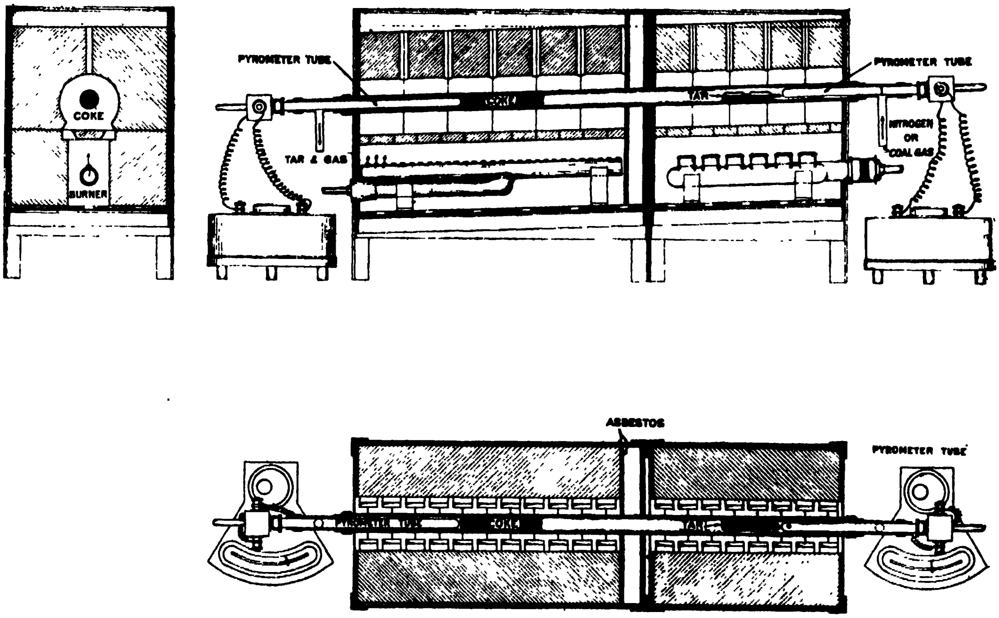

Fig. 24.

The apparatus used is illustrated in Fig. 24. A silica tube 36" long was heated by two separate furnaces so that the two parts of it could be maintained at different temperatures. In one portion of the tube was placed a boat containing 10 grammes of tar and in the other a quantity of coke to act as a heated contact material for the cracking of tar. A stream of nitrogen or coal gas was passed slowly through the tube from the tar boat end, and the gases and condensable liquids were conducted away from the opposite end. The method of procedure was first to heat the coke to a definite temperature, and then to raise the contents of the boat to a similar temperature over a period of either two or four hours. Representative samples of low and high temperature tars were used in these experiments and the results obtained are indicated in Tables C and D. It will be readily appreciated that the conditions of these experiments are very dissimilar to those which may be experienced during the cracking of tar in the carbonisation process on a large scale. Notwithstanding this, the results are of considerable interest.

As regards low temperature or primary tar, it will be seen that a fair yield of gas is obtained at temperatures as low as 600°C., a large proportion of the tar being recovered as a liquid which is of the nature of secondary tar. The figures relating to the quantity of tar recovered refer only to the tar condensed and do not include the residue in the boat. The residue obtained in the case of low temperature decomposition was a pitch-like coke, while that remaining at higher temperatures was virtually a coke containing practically no volatile matter. The yield of gas and tar recovered at 600°C is of the order of 62—74%, whereas at 800°C. the yield is less satisfactory. At 980°C. the process has already become poor from the point of view of total yield—the efficiency of cracking to tar and gas having been reduced to 30—40%. The tar recovered at this temperature is small in quantity and is of an inferior quality, being thick and viscous. Moreover, it is evident from the gas analyses that with increasing temperatures the gas itself has suffered considerable deterioration, the hydrocarbons having been largely decomposed, and the hydrogen percentage materially increased. The gas made at the lower temperatures is rich in saturated and unsaturated hydrocarbons and poor in hydrogen. The vital necessity of clearing the rich gas from the retort as quickly as possible and avoiding long contact with heated surfaces is clearly demonstrated in the experiment at 700°C. where an extension of the duration of the experiment from two to four hours results in a considerable degradation of the gas, the unsaturated hydrocarbons alone having decreased from 9 to 2.6%.

In dealing with the results obtained from the cracking of high temperature tar, it will be seen that the yields by weight of gas and tar at 1000°C. only amounted to 20%, while only 25% of the thermal value of the tar was recovered as gas—and very poor gas too. But, above all, it should be noted that the residual tar obtained by this procedure was little else than free carbon. In all cases of the cracking of this high temperature tar the gas consists mainly of hydrogen. Only a small percentage of unsaturated hydrocarbons is present, and methane is also a much less important constituent than in the gas from low temperature tar.

The conclusion that should be drawn from these experiments is that, directly a primary tar has been converted by cracking to secondary tar, it should be removed from the retort as quickly as possible, as the high temperature tar is a most unsuitable material to be submitted to the cracking process. The compounds present in high temperature tar are comparatively stable, having resulted from the decomposition of less stable bodies, and are only decomposable at the highest temperature of carbonisation. They decompose mainly by the elimination of hydrogen and the formation of compounds of increasing molecular complexity, and it would appear that the process ends finally with the formation of carbon itself. It has been suggested that, in view of the production of carbon in this way, the structure of the carbon molecule itself is far from simple. It is probable that the yield of gaseous therms obtainable from such a tar is very limited and can only be attained by sacrificing at considerable loss valuable constituents such as benzene and its homologues, thus rendering the tar of little value as an industrial commodity.

Before leaving the consideration of these experiments it should be noted from these results, and also from those shown in tables A and B, that the nature of the gas obtained during carbonisation is indicative of the nature of the reactions taking place in the retort. The greater the percentage of unsaturated hydrocarbons in the gas, the greater the quantity of primary tar which has been converted to high temperature tar and gas. On the other hand, a low proportion of these hydrocarbons may mean that the gas and tar have been subject to too long an exposure to heated surfaces.

The author is unable to draw a clearer picture of the process of tar cracking, but is sure that there is justification for supposing that the first products of high temperature

carbonisation are similar to those of low temperature working, owing to the fact that the heating of coal is a gradual process, however rapid it may be. Thus, a study of the cracking of low temperature or primary tar gives some indication of the reactions likely to occur in the high temperature process. Yields in actual practice are, in fact, likely to be superior to those obtained by artificially cracking primary tar, as that tar itself may have suffered some degree of decomposition before its recovery, whereas the primary tar obtained during the actual working of the high temperature process is cracked, so to speak, *in statu nascendi.*

The most important conclusion to be drawn from this work is that the cracking of high temperature tar in large scale practice is likely to be an uneconomical process. The yields and quality of gas produced in the small scale experiments are poor, while the nature of the tar itself is degraded. When one commences to manufacture gas from high temperature tar by the maintenance of excessively high temperatures or by allowing too great an exposure of the products of distillation to high temperatures, it is then that the thermal energy of the coal begins ruthlessly to be wasted.

Having considered some of the chemical principles and the mechanism of tar cracking the question now arises whether it is economical to replace tar by gas. This question carries with it a few problems of accountancy.

The underlying principle of gas works accountancy is that all charges upon the undertaking and the revenues from all sales, including those from by-products, shall be expressed wholly as a debit or credit to the cost of gas manufacture; the revenue arising from the sale of coke, tar, ammonia, etc., is utilised solely for the purpose of reducing the selling price of gas. It is proper, of course, that this should be, as these subsidiary operations are carried out for the purpose of making and selling gas cheaply, but, in order to compute the relative values of a therm in gas, tar and coke, it is necessary to view the revenues from these products from a different perspective and to cause each to bear its own cost of raw material and working expenses. The revenue from tar, both in the case of an undertaking possessing its own tar-works and in those cases where tar is dehydrated or disposed of directly, is expressed as net revenue, after deducting all direct charges incurred in obtaining that revenue. The same applies to coke and this method of gas works accountancy causes tar and coke to be residuals in every sense of the word, for no contribution has been made by them for their share of the cost of the original coal, for expenses incurred in the retort-house, and, indeed, for the general overhead charges common to a gas undertaking. In order that the therms of the coal may be distributed in the most remunerative way, it is desirable that the accounts of the gas undertaking be analysed to show these points clearly. Although the author does not claim to be an authority on questions of accountancy, he has attempted to analyse the accounts of the three London Companies to show the contribution of *tar as tar* and *tar as gas* in reducing the selling price of gas. In this way it should be possible to obtain a conception of the relative values of the gas therm and tar therm. The selling price of gas was determined assuming

(1) That the tar has no value and is thrown away.
(2) That the tar is sold as tar and that its net revenue is deducted from the cost of gas manufacture (the usual practice).
(3) That the therms of the tar are converted with 100% efficiency into gas therms, allowance being made for the additional costs incurred in purification and distribution of the gas but not for the cost of conversion of tar to gas.

The figures obtained from the balance-sheets of the London Companies are as follows :—

Selling Price of Gas per Therm.

	1920.	1921.	1922.	1923
	d.	d.	d.	d.
Tar thrown away	11.8	12.7	11.3	9.6
Tar sold as tar .	10.6	12.2	10.9	8.8
Tar sold as gas .	10.1	10.9	9.7	8.2

It is thus seen that in the four years under consideration the contributions of *tar in the form of tar* to reducing the selling price of gas in the case of the London Companies are 1.2d., 0.5d., 0.4d., and 0.8d., per therm. Contrast these figures with the reductions in the selling price of gas which would have resulted had all the tar been converted into gas with 100% yield and without incurring any process costs (except purification, distribution, etc.) —*viz.*, 1.7d., 1.8d., 1.6d., and 1.4d., per therm. On this basis, therefore, for the four years in question, tar in the form of gas would appear to have been respectively 1.4, 3.6, 4.0, and 1.7 times as valuable as it was in the form of tar.

It is difficult, however, to imagine that it is possible to convert all the high temperature tar into gas with 100% yield, but, provided the process of gasification of a part of the tar can be carried out with a high degree of efficiency without decreasing the market value of the remaining tar, and provided no additional retort-house costs are incurred, particularly in regard to stopped pipes, then the process of gasification is an economical one and should be practised. The degree to which tar gasification should be practised, however, is entirely dependent upon market conditions, and from the figures given above, it would appear that in the years 1920 and 1923 it would not have been a paying proposition to gasify tar to any considerable extent. Unfortunately, to determine the wisdom or otherwise of gasifying tar under any conditions of market price, calculation and some experimental determinations are required which cannot conveniently be practised universally. For general purposes, however, it may be stated that, year in and year out, it is economically sound to gasify as much tar as possible, as long as troubles are not being experienced with stopped pipes in the retort-house and the free carbon content of the residual tar does not exceed 15%. (This figure is given as one above which serious deterioration and waste of secondary tar may result.)

It is not proposed to deal with the characteristics of high temperature tar, but it may be of interest to note in passing that the free carbon content of the tar is not only an indication of the amount of secondary decomposition that has taken place, but is also an indication of the ease with which the tar may be distilled at the tar works. A tar possessing a high free carbon content has the power to emulsify with water and it becomes increasingly difficult to separate the water by distillation as the percentage of free carbon increases.

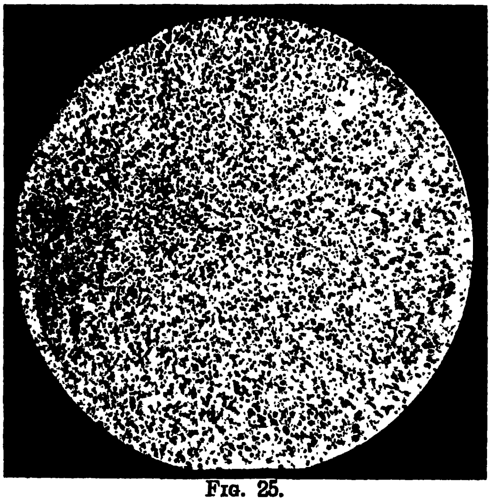

FIG. 25.

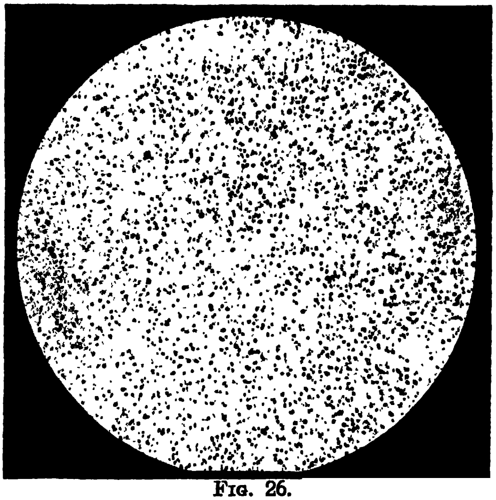

FIG. 26.

A ready method of observing the free carbon content of tar is to produce a microscopic slide smudge. Fig. 25 represents a smudge obtained from horizontal retort tar, and Fig. 26 one from vertical retort tar.

It is now proposed to attempt to determine the practical applications of the experimental results and theoretical considerations submitted in this lecture. Large scale experience, as well as the experimental work presented, demonstrates that the gas manufacturer who wishes to obtain a maximum gaseous thermal yield must carbonise coal as rapidly as possible. If two retorts of equal length and volume are taken and in one 6 cwt. of coal are carbonised up to 1000°C. in 6 hours, and in the other 10 cwt. are carbonised up to the same temperature in 10 hours, then the rate of heating will be greater in the case of the small charge, and it is a recognised fact that the old method of 6 hour work and 6 cwt. charges gives better gaseous therm yields. This method of working, however, carries with it so many disabilities in the form of stopped pipes (the costs of which cannot be computed in terms of therms per ton), that the quest for gaseous therms must of necessity give way when such troubles become acute. By increasing the weight of the charge and the period of carbonisation, the tendency is to conserve the tar, but there must come a stage when the tar yield is so high and the gas yield so low, that means have to be taken for promoting the cracking process. Moreover, considerable difficulty is experienced in preventing the very fluid tar from refluxing in the ascension pipe and the main disability of distilling 12 cwt. charges in 12 hours has been the loss of tar at the mouthpiece, though means have now been adopted for obviating this loss. To-day the tendency in horizontal retort working is to approach rapid carbonisation by raising the temperatures of the setting, so that a maximum charge of coal may be carbonised in a smaller number of hours than the weight of the charge in cwts.—*i.e.*, 10 cwt. in 8 hours—13 cwt. in 11 hours, etc. This is the method now being adopted to obtain the most rapid carbonisation in horizontal retorts without incurring the difficulties of stopped pipes, and it is the way in which high gaseous therm yields are obtained, although the tar yield naturally suffers slightly. There will, however, come a time when these modified weights and periods of carbonisation will tend to produce the disadvantageous conditions of the light charge; the author does not know precisely where the transition point lies. With the manufacture of fire-clay material of greater and greater fire-resisting and heat-transmitting properties, too great a degree of drasticity of distillation will tend to be reached, with the result that the limit of efficient working will be overstepped and retort-house disturbances will be incurred. Further, it has been shown that the cracking of tar as it is produced, or at the very instant after its production, differs appreciably from the cracking of secondary tar in a heated chamber. It follows from this that the cracking of tar in the coal substance is one thing, whereas the cracking of tar in the heated free space of a half-filled retort is an entirely different matter. The tendency of modern carbonising practice in horizontal retorts is to reduce the free space to an absolute minimum, and the author is certain that this is advantageous to the distillation process. What is required, however, is greater rate of heat transmission within the coal substance and this subject will be dealt with in the next lecture.

In conclusion, the author has demonstrated in one set of experiments the value of rapidly heating the charge. Rapid heating means the maintenance of high temperatures at the retort walls. The second set has shown the folly of attempting to gasify secondary tar, and at high temperatures, even primary tar, while the experiments have indicated also the necessity for preventing the products of distillation from coming into contact with highly heated surfaces. Good carbonisation is a fight between these two factors, and it is impossible to recommend any hard and fast rules of procedure to be adopted in the gas industry. Each gas undertaking is almost a law unto itself, governed by its existing plant, its geographical position, its market for by-products, and the requirements of its consumers. It has not been generally realised in the past that the conditions of carbonisation can be readily modified in order to give the required distribution of therms, and to-day it is not a difficult matter for a chemist to determine the conditions likely to be most remunerative and satisfactory with the plant at the disposal of the engineer.

Some of the hypotheses put forward for consideration may one of these days be found to be hopelessly unsound, but even if this be the case, the main point of this lecture will still hold—*viz.*, the inadequacy of thinking in terms of gaseous therms alone and the necessity for taking into consideration the total volatile therms in the form of both tar and gas.

The author takes the opportunity of acknowledging the help afforded by Mr. E. Anson Dyer, who has prepared the film used for demonstrating some typical chemical changes. The large amount of work entailed has been undertaken by him in the belief that this method of depicting chemical reactions will play an important rôle in the teaching of chemistry in the future.

LA VIE INDUSTRIELLE EN FRANCE.

Un Nouvel Appareil pour le Tracé Automatique de la Route sur la Carte à Bord des Navires.

La Marine française a expérimenté dernièrement un nouvel appareil traceur de route, inventé par le Lieutenant de vaisseau Baule. Cet appareil intègre tous les mouvements du navire et les trace sur la carte à mesure de la marche du bâtiment. Il décompose l'enregistrement du cap et de la vitesse en mouvements distincts, à une ou deux secondes d'intervalle ; il trace des éléments rectilignes très petits, qui pratiquement, se confondent avec la route exacte.

Dans cet appareil, la carte est tendue sur un cadre au-dessous duquel est disposé un mécanisme électro-mécanique. Sur la carte même se trouve une bille en acier enduite d'encre, qui se déplace en laissant une trace sur la carte, sous l'action d'un électro-aimant faisant partie du mécanisme. Ce mécanisme se compose principalement d'un chariot portant l'aimant, capable de se déplacer le long d'un bras rectiligne articulé à un côté du cadre ; ce chariot repose d'autre part sur un plateau qui peut recevoir un mouvement rectiligne alternatif, et un mouvement de rotation. Le mouvement de rotation est asservi avec celui du compas du navire ; il traduit donc sur la carte les changements de direction.

Le tracé des secteurs représentant les parcours pendant chaque unité de temps est effectué sous l'influence du fonctionnement d'un loch à bulles. Dans cet appareil, un réservoir d'air comprimé à faible pression laisse échapper par une soupape une certaine quantité d'air dans un tube parcouru par un courant d'eau résultant de la marche du navire. Les bulles d'air passent successivement sous un plot électrique disposé à l'arrière du tube. Chaque bulle qui passe interrompt le courant électrique d'une pile qui passe par ce plot, ce qui commande en même temps l'envoi de la bulle suivante. La succession des bulles peut ainsi être employée à envoyer dans un circuit électrique des impulsions en nombre proportionnel à la vitesse, toutes les fois, par exemple que le navire a parcouru 1/200ème de mille. Ces impulsions sont traduites sur le traceur de route, au moyen d'un mécanisme trop compliqué pour être décrit ici, par un déplacement du chariot, qui trace sur la carte un secteur de 1/200ème de mille. Ensuite, si la direction a changé, le plateau tourne d'une manière correspondante, puis s'immobilise pour le tracé du secteur suivant, et ainsi de suite.

Avec cet appareil, le rôle de l'officier de quart se borne à la vérification de l'échelle suivant la latitude. Le traceur a encore l'avantage de se prêter facilement à la répétition du tracé en un point quelconque du navire : dans le bureau ou le blockhaus du commandant, par exemple. Un appareil simplifié, relié à l'appareil principal par des connexions électriques suffit à cette répétition.

Des expériences faites sur des trajets compliqués ont montré l'exactitude du fonctionnement de l'appareil.

L'Usine Électrique Marémotrice de l'Aber-Wrach, près de Brest (Finistère).

Depuis plusieurs années, les ingénieurs français s'occupent d'utiliser la force des marées pour la production d'électricité, dans des groupes turbo-alternateurs actionnés par le flux et le reflux de la mer. Le principe est très simple, mais l'application l'est beaucoup moins, car le fonctionnement de l'usine est forcément intermittent. Plusieurs combinaisons ont été proposées pour atténuer l'irrégularité de la puissance, et l'une des plus intéressantes est celle de l'Ingénieur belge Defour. Ce n'est cependant pas ce système qui a été adopté pour la première installation marémotrice qui vient d'être décidée en France. On s'est arrêté à une conception très simple de l'usine marémotrice, en demandant à une seconde usine ordinaire de régulariser son débit en fournissant à chaque moment la puissance supplémentaire au réseau.

L'Etat français ayant décidé de faire construire une première usine marémotrice, pour mettre au point l'étude pratique de ce problème, a choisi la solution de deux usines conjuguées, situées à 25 Km. au nord de Brest, elles alimentent ce port de guerre, qui a également une certaine importance industrielle.

L'usine marémotrice de 6,000 h.p. sera installée sur l'estuaire de l'Aber-Vrach. Elle sera conjuguée avec une usine hydro-électrique d'eau douce qui utilisera la force de la rivière le Diouris, affluent de l'Aber-Vrach ; les eaux de ce cours d'eau seront retenues par un barrage de 30 mètres de hauteur. Une ligne à haute tension reliera les deux usines avec Brest.

Une loi de Décembre, 1923, avait fixé la participation financière de l'Etat à cette entreprise, et deux décrets d'Août, 1924, viennent de concéder l'exploitation des deux usines et de la ligne à haute tension à la "Société financière pour l'Industrie." Ainsi se trouve close la période de préparation, et celle de réalisation vient de s'ouvrir. On peut ainsi espérer voir bientôt construite la première usine marémotrice française.

L'Electrification des Chemins de Fer de la Banlieue de Paris.

Les Chemins de fer de l'Etat exploitent à l'ouest de Paris un important réseau de banlieue qui comporte actuellement 800 kilom. (500 miles) de voies simples et dessert la partie la plus peuplée des environs de Paris. Il possède dans Paris 3 grandes gares : celles de Montparnasse et des Invalides sur la rive gauche, et celle de Saint-Lazare sur la rive droite de la Seine. Cette dernière assure la plus grande partie du trafic : sur 70 millions de voyageurs amenés par an avant la guerre par le réseau de l'Etat, 60 millions arrivaient par la gare Saint-Lazare. Le nombre des voyageurs quittant la gare pendant l'heure la plus chargée (de 18 h 30 à 19 h 30) était de 13,000 en 1910, 18,000 en 1920, et dépasse actuellement 23,000.

Pour répondre à un tel accroissement de trafic, on a décidé d'électrifier les lignes de petite banlieue.

Les deux premières lignes électriques, les plus chargées, viennent d'être mises en service, ce sont celles de Paris à Bois-Colombes, et à Bécon-les-Bruyères.

La traction est assurée au moyen d'automotrices à courant continu à 650 volts. Le courant est produit dans deux usines principales appartenant au chemin de fer, l'une à Bezons, l'autre aux Moulineaux, de 20,000 kilowatts chacune, cette puissance devant être doublée plus tard. Le courant est produit sous forme triphasée à 15.000 volts, et il est transformé en courant continu dans une quinzaine de sous-stations réparties dans tout le réseau.

Les automotrices et les remorques sont de construction analogue. Elles sont entièrement métalliques, établies sous la forme d'une "caisse-poutre" de grande résistance. L'automotrice est portée par deux bogies moteurs, chaque bogie étant actionnée par deux moteurs de 165 h.p.; la puissance totale est donc de 660 h.p. Les trains sont formés d'éléments de traction indécomposables, constitués par une automotrice et une remorque. Suivant l'affluence des voyageurs, les trains sont constitués de 1 à 4 éléments semblables, et la puissance est ainsi toujours proportionnelle à la charge. Pour faciliter la formation de ces trains, les extrémités de chaque élément sont munis d'un attelage automatique. La commande peut se faire, soit de la cabine principale de l'automotrice, soit d'une petite cabine auxiliaire, à l'extrémité de la remorque, pour la marche en sens inverse.

L'équipement est du type Sprague multiple Unit Control; il est constitué de façon à pouvoir fonctionner indifféremment sous 650 volts ou sous 1,500 volts, pour le cas où l'on adopterait plus tard cette dernière tension; l'appareil de manœuvre principal, du type électropneumatique, est placé dans la cabine du wattman, de sorte que toutes ses parties sont facilement accessibles.

Un élément de traction, formé d'une automotrice et d'une remorque, peut transporter normalement environ 370 voyageurs, dont 70 de première classe, de sorte qu'un train moyen de 3 éléments en transporte plus de 1,000. Aux heures d'affluence, le matin et le soir, les trains sur les deux lignes électrifiées partent à intervalles de 15 minutes, de sorte que les gares intermédiaires communes aux 2 lignes sont desservies à intervalles de 7½ minutes.

La traction électrique sera mise en service sur une seconde zone l'année prochaine, et l'ensemble du réseau de banlieue sera électrifié en 1927.

OBITUARY.

◆

Edward Tancred Agius.—By the death of Mr. E. T. Agius, from heart failure, on September 21st, at his residence, No. 3, Belsize Grove, Hampstead, the Society loses a supporter of long standing, he having been elected a member in 1896. Mr. Agius, who had reached his seventy-sixth year, was senior member and managing director of Messrs. E. T. Agius, Ltd., of 10 and 11, Lime Street, E.C., a firm established over half a century ago and possessing branches at Cardiff, Newcastle-on-Tyne, Glasgow, Liverpool, Swansea, Hull, Southampton, Genoa, Malta and Alexandria.

The oldest active member of the Baltic Shipping Exchange, he was also a member of the London Chamber of Commerce and of many other chambers of commerce; Commissioner for Malta at the British Empire Exhibition; and since the autumn of 1923 he has represented the interests of Malta on the Dominions and Colonies Section Committee of the Royal Society of Arts. He was well known for his generous assistance to deserving charities.

VICTORIA AND ALBERT MUSEUM.

The Victoria and Albert Museum has recently acquired, through the generous gift of Mrs. Gabrielle Enthoven, her Collection of Play-Bills and Theatrical Programmes, representing the active enthusiasm of many years. The Collection, which is by far the largest in existence, contains many prints, autographs and architectural drawings as well as play-bills, and comprises over 50,000 items ranging from the beginning of the 18th century until modern times. The earliest bill is for a performance of "Comus," at Covent Garden in 1730, and the Collection contains almost complete sets of the nightly play-bills, beginning in the 18th century, of theatres such as Drury Lane, Covent Garden, the Haymarket, etc.

The play-bills have already been of service in the identification of drawings of costume and scenery, and many of the bills have considerable literary and dramatic interest. The Collection includes the announcement of the first appearance on the London stage of "a young lady" who was afterwards to be known as Mrs. Siddons, and the bill for the first performance of "The School for Scandal." There are 240 bills referring to Garrick, and almost complete sets for Peg Woffington, Kean and Macready. Mrs. Enthoven's object, however, has not been to collect individual curiosities but to make her collection as complete as possible in order that it may serve as reliable material for the art of the theatre and for theatrical history, which, in the past, has been notoriously inaccurate from the very real difficulty of finding trustworthy records.

The play-bills are to be stored in the Department of Engraving, Illustration and Design, which, it will be remembered, was responsible for the International Theatre Exhibition held at the Museum in 1922. When the work of cataloguing and indexing the collection has been completed the new material will be available in the Students' Room of the Department, which contains a steadily growing collection of designs for theatrical scenery, costume, and architecture.

The main portion of the Enthoven Collection up to the year 1870 has already been placed in the

Museum, and the work of continuing the collection and of filling up gaps, particularly in connexion with modern plays, is being carried on with Mrs. Enthoven's valuable help. Every effort is being made to render this collection as complete and authoritative as possible; and Mrs. Enthoven and the Museum Authorities will welcome gifts of any play-bills or programmes which are missing from the collection.

DUMFRIES AND GALLOWAY BACON.

Dumfries-shire and Galloway have long been celebrated in Scotland for their dairy farms, and there are many well-known herds of Ayrshire and other breeds of cattle in both localities. Naturally, this gives rise to pig-breeding; as separated milk from butter-making, and whey from cheese-making, form excellent foods for pigs.

Generally speaking, the breeds of pigs which are mostly favoured in the South-West of Scotland are three in number, *i.e.*, the Large Black, Large White Yorkshire, and Middle White Yorkshire. These pure breeds and their various crosses are largely favoured by bacon-curers, and there has been much development of pig-breeding in this part of Scotland during recent years, the demands of the bacon-curers having increased very greatly.

Bacon-curing is the natural corollary of pig-breeding, and there is plenty of room in Scotland for development in this particular industry, as the imports of bacon and pig products from overseas are enormous.

The value of such imports into Great Britain at the present time is around 55 million pounds per annum, and it is only reasonable to suppose that a large proportion of this business could be retained at home, if pig-breeding were more developed throughout the country. The home article, also, always commands the highest price.

There have been several new bacon factories organised in Scotland during recent years. The latest of these is at Dumfries, where some very handsome buildings at Terregles, near the town, have been acquired, and are being converted into a modern bacon factory from the designs of Mr. Loudon MacQueen Douglas, F.R.S.E., of Edinburgh. The factory has been equipped, to begin with, to handle about 250 pigs a week; and the lay-out has been arranged so that the capacity of the factory can be doubled with very little trouble.

The work to be carried on will be the production of Scottish rolls, hams, and Wiltshire bacon, and it is confidently anticipated that there will be a large demand for the Scottish-cured Wiltshire sides.

The factory will embrace all the different departments which go to make up the general success of such an establishment, and the most modern machinery and appliances are being installed in the sausage department, ham cooking, and general cooking room, lard department, and bakery and by-products department. It is very little use indeed to try to make a bacon factory a success without specialising in these auxiliary departments, and it is a curious fact that there seems to be unlimited demand for these secondary products, more especially when they are prepared by an expert, such as has been appointed to the Dumfries factory.

It is hoped that the factory will be in a position to receive pigs in large numbers shortly, and that the products will soon become familiar in Scotland and elsewhere.

CEMENT MANUFACTURE IN THE EMPIRE.

The manifold uses of cement and especially its employment for the manufacture of concrete, which is so largely used at the present day in place of brick and stone for structural purposes, render it of no little importance that all countries should be able to obtain cement for local use at a reasonable cost. In many overseas countries, particularly those remote from the present centres of production, the use of cement is greatly restricted owing to the heavy cost of shipment and the consequent high price of imported supplies.

Portland cement is already being made in large quantities in several overseas countries of the Empire, such as Canada, Union of South Africa, Australia, New Zealand and India, whilst operations on a smaller scale are being carried on in the Sudan, Rhodesia and Malaya. It seems probable that the raw products required for cement manufacture exist in nearly all parts of the Empire, but hitherto little information has been available regarding the possibilities of establishing a cement industry in most of the Crown Colonies and Protectorates. Considerable attention has been devoted to this question in recent years by the Imperial Institute, where a fully equipped cement-testing laboratory has been installed, and the first part of an interesting article on the subject is published in the current issue of the quarterly "Bulletin of the Imperial Institute." An outline is given of the manufacture and properties of different kinds of cement, special attention being devoted to the characteristics required in the raw materials used for the several classes of cement now employed in building. This is followed by particulars relating to the opportunities of cement manufacture in the Crown Colonies and Protectorates; under each country is given an account of the deposits so far known, results of tests carried out at the Imperial Institute, and a discussion of the prospects of establishing a cement-making industry. In the first part, now published, British West Africa is dealt with. It is shown that cement materials occur in Nigeria which are worth further investigation and technical trial, particularly in view of the existence in the country of deposits of coal and lignite which could be used as fuel. Suitable limestones appear to occur also in the Gold Coast, but there seems to be little chance of finding in Sierra Leone materials in sufficient quantity for cement manufacture.

CANTOR LECTURES.

A STUDY OF THE DESTRUCTIVE DISTILLATION OF COAL.

By **Edward Victor Evans**, O.B.E., F.I.C.,
Chief Chemist and Products Manager, South Metropolitan Gas Company.

Lecture III.—*Delivered March 10th,* 1924.

In the previous lecture it was demonstrated that rapid carbonisation is essential if the best yields of gaseous therms are to be obtained. It will be remembered that this was considered to be due to the fact that with rapid carbonisation the average temperatures maintained throughout the coal charge are higher than in the case of slow carbonisation and that in consequence the tar is subjected to a higher degree of cracking, with the result that gas is produced at the expense of tar. It was decided that this practice of converting tar into gas was generally the most economical one to adopt in the gas industry, provided that the cracking process was effected without decreasing the market value of the resulting tar and causing retort-house troubles in the form of stopped pipes. The question, therefore, is how to modify the carbonising process in order to increase the rate of heat transmission not only through the retort walls, but also through the charge itself. The use of retorts manufactured of a material which is a better conductor of heat than the fire-clay employed to-day will solve the first of these problems, and, in America, carborundum is coming to the fore in this connexion. The rate of heat transference through the coal charge, however, will still be slow, no matter how rapid it may be through the retort walls, and the more important problem which is presented for solution is that of increasing the conductivity of the coal.

Before passing on to a consideration of the question of treating coal prior to carbonisation in order to increase the rate of heat transmission, the author wishes to describe the physical changes which are believed to take place when ordinary coal is undergoing carbonisation. In a well-filled horizontal retort, with some 3in. or 4in. space above the top of the charge, it is probable that the periphery of the charge, which is in direct contact with the walls of the retort, very rapidly attains a high temperature. The rate of heat transmission to the centre of the charge would, if the material were not undergoing constant physical change, be very rapid during the first few hours, but would gradually decrease as the temperature of the charge approximated that of the retort wall. The physical condition of the coal, however, does change during the period of carbonisation, and particularly during the first few hours, and it is these changes which are deemed largely responsible for the low heat conductivity of the charge. It is known that certain resinous constituents of the coal—the so-called gamma compounds—melt readily, and it is probable that the fusion of these constituents is responsible for the cementing together of the charge. It is conceived that the outer crust of the charge is very rapidly carbonised and cemented into coke and that this may take place even while, in the centre of the charge, there exist pieces of coal which still retain their identity although perhaps they may have become slightly plastic on the surface. As the temperature of the mass gradually increases there appears to be produced a plastic layer which forms a semi-liquid wall enclosing coal which up to this point has remained practically unchanged. As this coal undergoes decomposition, some of the gaseous products force their way through the plastic layer, which in consequence becomes much distended by the bubbles of gas. Meanwhile the semi-liquid layer itself is undergoing decomposition, the gases evolved adding to the effect of those from the decomposing coal within. As decomposition proceeds, the layer gradually loses its plastic nature and ultimately hardens, giving the cellular structure typical of an ordinary gas coke. It is the cellular nature of the carbonised mass which is the cause of the low heat conductivity of the material and it is thus indirectly the plastic layer which impedes the rate at which heat is transmitted into the charge. It is imagined that the gases evolved during the whole of this process fight their way to the wall of the retort either through the plastic layer or through the cellular coke already produced, and if evolved at the side or bottom of the retort, travel between the charge and the retort wall until they reach the space above the charge. An untold hubbub must take place as the plastic layer finds its way towards the centre of the charge and is there gradually heated to the decomposition point. Whereas the volatile matter evolved during the early stages of carbonisation had to run the gauntlet of the heated outer layers only, now every bubble of gas produced must fight its way through the whole mass—through tar and other semi-liquid products—until it finds a means of exit through the innumerable channels of the partly and fully cokified portions. Each step it takes brings it into a hotter zone and the molecule which, as may be imagined, started from the centre of the charge with a wonderful degree of complexity, is submitted to such disruptive influences that by the time it finds its way through the coke it has been reduced to a comparatively simple form. Even then it still has to run the gauntlet of the space above the top of the charge. In all these reactions of decomposition a certain time of contact is necessary and the final form taken by this molecule will depend largely upon whether it be withdrawn from the retort before sufficient time contact has been given to break it down completely. A knowledge of chemistry does not help very much in the interpretation of this picture—in fact it rather tends to complicate matters—for it allows one to appreciate better not only the complexity of the reactions, but also the almost limitless range of reactions that may take place.

This picture of the physical changes which coal is supposed to undergo on heating has indicated that indirectly it is the plastic layer which prevents heat being rapidly conducted through the coal charge—a conclusion which has been reached by a number of investigators. The problem of increasing the heat transmission of the coal substance itself will be solved, therefore, by adopting suitable means for preventing the formation of the plastic layer. The absence of the plastic layer and the avoidance of large cells will allow rapid penetration of heat through the charge, and in consequence one would naturally expect, from the conclusions arrived at in the previous lecture, that an increased yield, not only of gaseous therms, but also of total volatile therms, will be realised. It is known that expansion of the charge during carbonisation may be avoided, or at least very materially reduced, by admixing with the coal to be carbonised an inert absorbent material such as coke or coke-breeze. This material, if intimately mixed, will prevent the formation of a plastic layer by absorbing the tar-like matter formed and by providing an infinite number of small pores and channels through which gases may escape. Moreover, the tendency of the material to expand during carbonisation will be reduced, as the large cells which originate from the plastic layer will no longer be formed. It is these large cells which constitute such a great impediment to heat transmission, and with the particles of coal and inert material lying in close proximity during the whole carbonising period, a small-celled structure will be produced, with the result that the rate of heat transmission will be considerably augmented.

It can be demonstrated by experiment that, by admixing coke with coal and briquetting the mixture without a binder, the rate of gas evolution is materially increased. For this purpose equal weights of the same coal, one sample of which is briquetted with 25% of coke, are heated in silica bulbs in a furnace, the temperature of which is from 900° to 1000°C. The rate of gas evolution is found to be materially greater in the case of the briquetted mixture, showing that the effect of the inert absorbent material in the coal mass is to increase the rate of heat transmission. Such an experiment, although on an exceedingly small scale, demonstrates clearly the difference in the respective rates of carbonisation of coal alone and of coal briquetted with coke. The results of some experiments, carried out on a somewhat larger scale, using quantities of the order of a retort charge

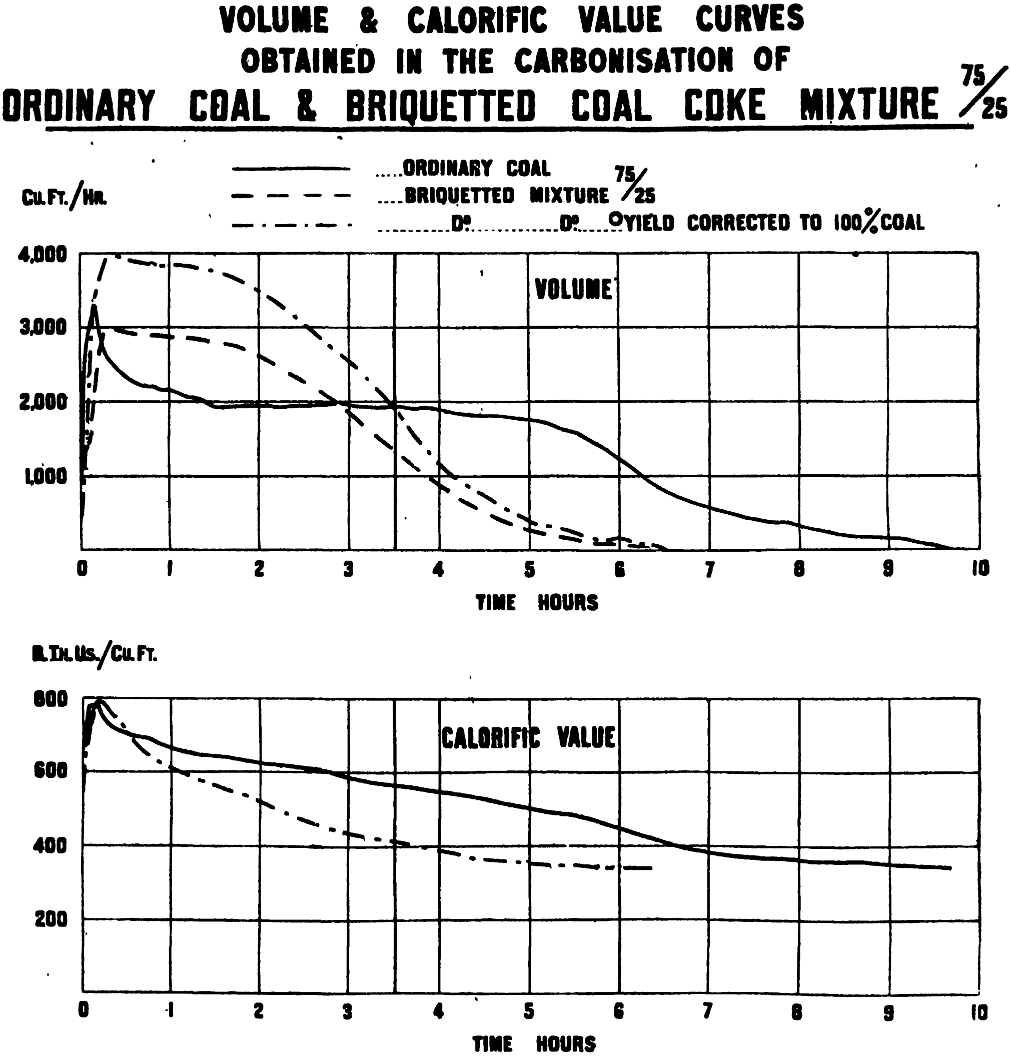

Fig. 27.

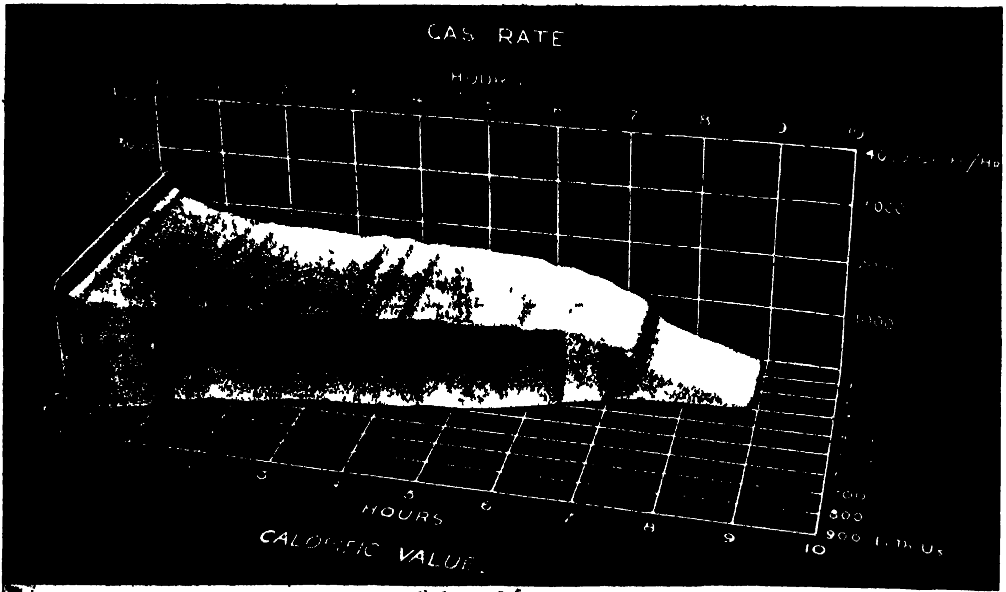
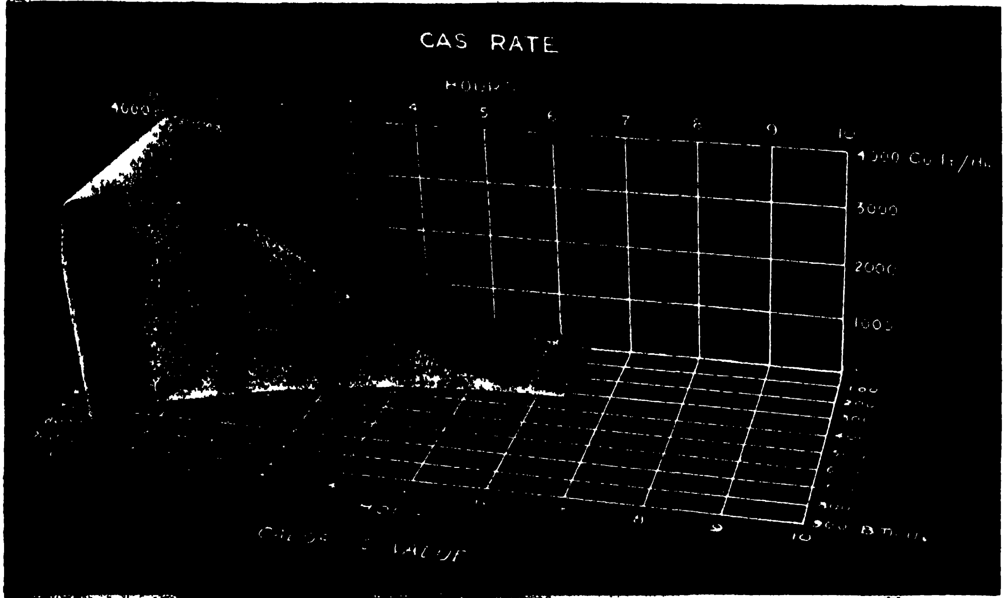
are, however, of still greater interest. In Fig. 27 are seen the volume and calorific value curves plotted from the results obtained in the carbonisation of a briquetted 75/25 mixture of coal and coke; the curves are compared with those obtained as the result of carbonising a similar weight of coal alone under similar conditions. The results relating to the briquetted mixture have also been corrected to 100% coal, and the curves obtained in this case show how the rate of distilling the coal is affected by briquetting with coke.

These curves indicate very clearly that the nature of the carbonisation process is entirely changed when a briquetted coal-coke mixture is used instead of ordinary coal. The carbonising process has been accelerated to such an extent that the whole of the gas has been expelled from the briquettes in 6½ hours, as compared with 9½ hours in the case of untreated coal. The difference between these two periods is 31½%, and if allowance be made for the fact that inert material is mixed with the coal to the extent of 25% it will be found that the throughput of actual coal will be increased slightly when 75/25 briquettes are carbonised. Striking though the diagrammatic curve may be, it is here that the thermal models employed in the first lecture show so admirably the difference in the rate of carbonisation produced by the admixture of an inert material with the coal. Fig. 28



COAL



BRIQUETTED COAL-COKE MIXTURE, 75/25

Fig. 28.

shows the thermal models obtained from carbonisations of ordinary coal and of a briquetted coal-coke mixture. The principle of these models was described in Lecture I.

In the first lecture it was also demonstrated how striking was the difference between the amounts of useful work effected in the retort during the middle ten minute periods of the first and last hours of the carbonising period. Striking though this is, the difference is greatly accentuated in the case of the carbonisation of briquetted coal-coke mixtures. Fig. 29 shows three sections taken from the thermal model obtained from the 10-hour carbonisation of ordinary coal and two sections taken from the

thermal model relating to the carbonisation of an equal weight of a 75/25 coal-coke mixture. The most outstanding observation to be made is that when the briquetted material has lost practically all its volatile matter a large amount of work is still being effected in the case of the slower carbonisation of ordinary coal.

It is quite evident, therefore, that the admixture of an inert material with coal

increases the rate of gas evolution and the next question that arises is whether this enhanced rate of gas evolution is accompanied by the superior thermal yield of gas which is to be expected from the results of the laboratory investigation already described in Lecture II. These results are reproduced in an abbreviated form in Table E.

Carbonising trials with briquetted coal-coke mixtures have been carried out in an experimental plant, but up to the present we have failed to operate the setting in such a way as to obtain through the retort walls the quantity of heat required to effect the degree of tar cracking necessary to give the enhanced thermal yield of gas. What has been done, however, is to obtain the increased volatile therm yields such as resulted from the laboratory experiments. Some typical results obtained are given in Table F:—

TABLE F.

CARBONISING RESULTS FROM DURHAM COAL AND BRIQUETTED MIXTURES OF SAME COAL AND COKE (75/25).

———	Ordinary Coal.	Briquetted Mixture.	
		A.	B.
Yield of gaseous therms per ton of coal ..	74.7	68.2	71.1
Yield of tar therms per ton of coal	16.1	31.0	27.5
Total yield of volatile therms per ton of coal	90.8	99.2	98.6

In the A series of experimental trials, involving altogether 22 tons of briquettes, the combustion chamber temperature was maintained some 50°C. lower than in the B series, where a total of 12 tons of briquettes was carbonised. With the increased combustion chamber temperature a higher gaseous thermal yield has been obtained at the expense of tar, but even under these conditions the process has been operated only as a tar conserving one. Still, notwithstanding the 25% of inert material introduced into the retort, a small increase is to be observed in the throughput of true coal.

It is probably unnecessary to point out that the carbonisation of this briquetted material raises manifold technical problems which are being dealt with as rapidly as time permits. The presentation of these results, however, will be sufficient to demonstrate that an entirely new field is open for the production of a more economic distribution of the therms of the original coal. As many as 8 to 9 additional volatile therms, which are several times more valuable than non-volatile therms, have been obtained from the particular coal under test. These additional volatile therms are, as indicated in Lecture II, obtained at the expense of coke, and it will subsequently be necessary to account for them theoretically. It will be appreciated that the distribution of the thermal energy of coal in this new way will constitute an important contribution to the coal conservation problem. The tar obtained in these experiments possesses a somewhat higher free carbon content than that produced under similar conditions from ordinary coal. The nature of the coke produced, however, is an outstanding feature of this process. It possesses very distinct advantages over the solid fuel produced from the rapid carbonisation of ordinary coal.

(Here an experimental carbonisation of coal and a coal-coke mixture was carried out in silica test tubes and it was demonstrated that the friable product obtained from ordinary coal under the conditions of the experiment was replaced by a stabilised and dense material in the case of the briquetted mixture.

Demonstrations were also made which might be termed "experiments in parenthesis" illustrating the remarkable modifying action of inert material on the carbonisation of sugar and the burning of mercuric thiocyanate, the ash of which results in the so-called "Pharaoh's serpents.")

The question of carbonising briquetted mixtures has here been presented from the point of view of obtaining the maximum yield of volatile therms; other investigators have recommended the addition of inert matter to the coal in order to obtain a resulting solid fuel of high density and with a high degree of combustibility. That this solid fuel is indeed superior to coke has been admirably shown by E. C. Evans. It possesses a greater heat conductivity than ordinary coke, owing to the fact that the the absence of the plastic layer has prevented expansion of the coal, with the result that a small-celled structure is produced. In consequence, combustion proceeds with greater velocity, while the powdered ash, instead of containing as much as 10 to 20% of combustible matter (as is often the case with coke ash), is practically free from carbon. Many investigators are engaged in a study of this fuel and for several years the author

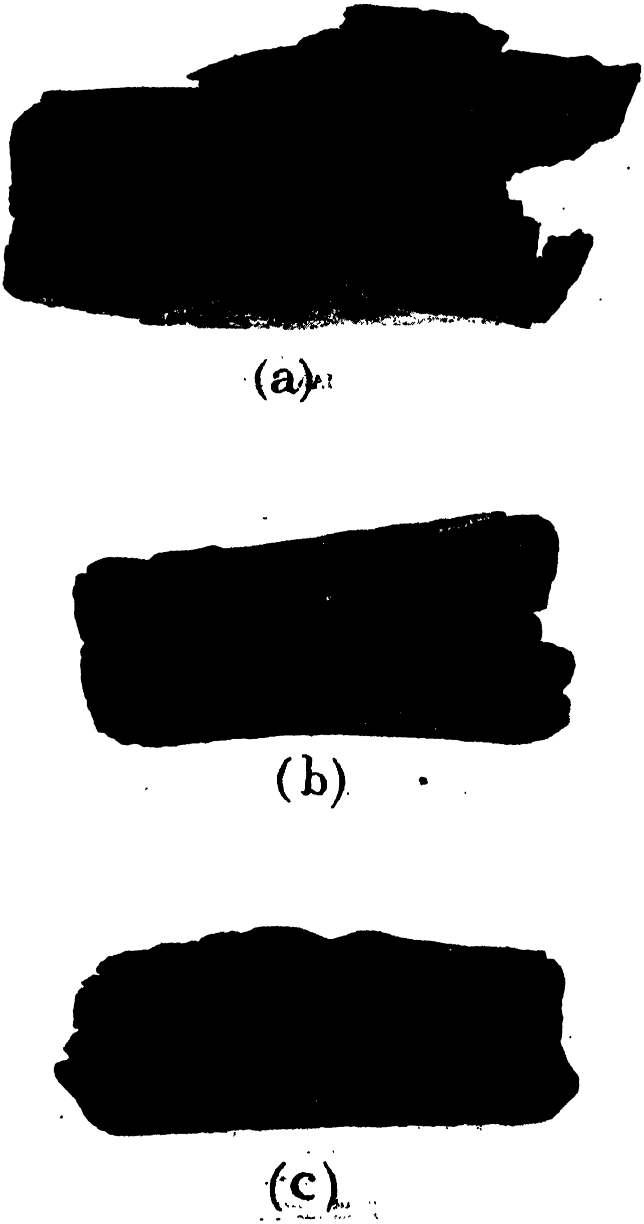

Fig. 80.

has been working upon this question — recently in collaboration with E. R. Sutcliffe and E. C. Evans. It is to their publications and to those of Roberts and others that reference should be made for more detailed information regarding the virtues of this fuel.

It has been demonstrated that the process of carbonisation of a briquetted coal-coke mixture possesses distinct advantages, in that it results not only in an enhanced yield of volatile therms, but also in a very superior solid fuel. Before discussing the advantages and disadvantages of such a process from the gas manufacturer's point of view, it is proposed to deal with the following question :—viz., what is the origin of the additional volatile therms produced in briquette carbonisation ?

It will be remembered that originally it was decided to admix an inert material with coal in order to break up the plastic layer which prevented heat being readily transmitted through the mass. In the first place it is essential to admix the correct proportion of coke, as will be seen from Fig. 30, which shows sections of briquetted fuel from (a) 100% coal, (b) 85/15 coal-coke mixture, (c) 75/25 coal-coke mixture. It will be observed that while the formation of the plastic layer is reduced in the case of 85/15 coal-coke mixture, it is almost entirely avoided when as much as 25% of coke is admixed with the coal. That there is practically no plastic layer formed when the right proportion of coke is used in the briquette may be proved by the fact that if one arrests the distillation process at any time after the third hour the volatile matter remaining is evenly distributed throughout the briquette. The importance of this observation in supporting the contention that the plastic layer is avoided in briquette carbonisation is apparent and it contributes very materially in making clear the new carbonising picture.

Fig. 31 shows sections of ordinary coke and of that obtained from the carbonisation of a 75/25 coal-coke mixture. From these sections there may be seen on the one hand the particular cellular structure so typical of ordinary coke—the result of the ravages of the plastic layer—and on the other hand the very dense small-celled coke which is produced when the formation of the plastic layer is avoided. Now the larger cells of the normal coke necessitate a considerable amount of binding material, and a coking coal is one in which sufficient binding material remains after the period of expansion (*i.e.*, when the plastic layer is bubbling and foaming) to allow the coke particles to be adequately cemented together during the shrinking process. With the production of a small-celled coke, such a large quantity of binding material is not required, and it is conceivable that a large proportion of the parent substance from which the binding material originates is distilled away and converted into volatile therms. The author believes that it is this binding material which is the origin of the additional therms produced in the rapid carbonisation of coal and in briquette carbonisation. In order to develop this hypothesis a further experiment will be shown in which equal weights of coal, in the form of coal alone and of a coal-coke mixture containing 25% coke, are heated in silica bulbs. The only difference between this experiment and the similar experiment already given is that on this occasion the silica bulbs are heated directly by means of Meker burners, so that there is developed a very high heat potential in relation to the weight of coal taken. In the previous experiment special means were adopted to maintain the necessary temperature of carbonisation with a considerably lower heat potential more in accord with large scale practice. It will be observed that the rate of gas evolution in the present experiment is practically the same in both cases, owing to the fact that the quantity of heat available is so great that the coal charge is heated just as rapidly as the briquetted mixture. Under such conditions of drastic heating it can be imagined that practically the whole of the binding material is converted into volatile matter.

Now this observation is of great interest to the gas chemist. It is often said—and with good reason—that the carbonisation of coal in the laboratory is of little value in forecasting the results eventually to be obtained on the large scale. That the laboratory distillation fails is due partly to the fact that the furnace is out of all proportion to the weight of coal charge used, and the amount of binding material evolved as volatile matter is higher than would be realised on the large scale. Further, the size of the retort in relation to the coal charge is also usually out of keeping with large scale conditions and a degree of tar cracking is practised which causes the results to be materially different from large scale experience. The

COKE

COKE FROM BRIQUETTED COAL COKE MIXTURE

Fig. 31.

difficulty of designing laboratory apparatus to yield results comparable with large scale practice is generally realised, but the author does not know whether the underlying cause of these differences is appreciated.

If this hypothesis be correct—that the material which cements together the cell structure of coke may under certain conditions be distilled away as volatile matter—the question arises as to what is the maximum yield of volatile therms that may be obtained in the carbonisation of coal? This the author cannot answer, but one is faced with the fact that a small scale laboratory experiment (see Table E) yielded nearly 100 therms of volatile matter from a coal which under normal conditions of working has given only 90 and this improved yield should be the aim in large scale practice. It may be pointed out in passing that if this hypothesis regarding binding material be true then the usual test for volatile matter in coal is of very limited utility for computing the value of a coal for gasmaking purposes. The test is carried out by heating very rapidly an exceedingly small quantity of coal; and under these conditions of drastic heating the whole of the volatile matter is evolved, the coke is useless, and the result is one appreciably different from that realised on the large scale. What should be known in computing the value of a coal is the proportion of the total volatile matter which is recoverable as volatile therms under the conditions of the practical process to be adopted.

It will be remembered that the carbonising experiments of the previous lecture indicated that not only a maximum volatile thermal yield was obtainable under the conditions of rapid heating, but also that moderately slow carbonisation was a tar conserving process and very slow carbonisation a coke conserving one. The conclusion was then arrived at that, in the slowest process, tar distillation took place as well as gas evolution and that the pitch left by the distillation of tar contributed to the yield of coke. It is now seen that, to a greater or less extent, the tendency to augment the coke yield takes place in all carbonisation processes and that the slower the process the greater the quantity of binding material left in the coke. It would appear that the thickness of the plastic layer is dependent upon the rate of heating and that a quickly heated coal will produce an unsatisfactory coke (unless some special means such as briquetting be adopted) for the binding material required for the purpose of cementing together the large cells will have been distilled away or cracked into gas before the shrinking process commences. This is actually the case; the most satisfactory coke is produced by heating very heavy charges for long periods, while the coke resulting from the rapid carbonisation of light charges yields a high percentage of breeze. The problem, therefore, resolves itself into either determining the minimum amount of binding material required for the coke to be a satisfactory material or, preferably, discovering some means of treating the coal substance prior to carbonisation so that upon cokification it will yield a product which requires a minimum amount of binding material to make it mechanically stable. The latter problem has already been solved, for it has been demonstrated that the carbonisation of briquetted coal-coke mixtures results not only in an increased yield of volatile therms, but also in a compact solid fuel which is far superior to ordinary coke. The author does not wish to overlook the point that carbonisation may take place under conditions which prevent a large degree of expansion of the coke, and it is possible that the prevention of expansion by compression may result in an enhanced degree of tar cracking. Such a process does not, however, result in the recovery of additional volatile therms, because the formation of the plastic layer is not avoided.

It is now proposed to examine briquette carbonisation from the point of view of the gas manufacturer and to discuss the advantages and disadvantages of such a carbonising system. There is no necessity to deal with the financial advantages accruing from the production of an additional 8 to 9 volatile therms per ton of coal carbonised, but at this stage it is proposed to consider what is perhaps equally important to the gas industry—namely, the production of a superior solid fuel. The author is certain that, if greater attention were paid to the manufacture of solid fuel, whereby its application might be greatly extended, a much wider market would be established, a greater throughput of coal would be possible, and the selling price of gas consequently reduced. Gasworks coke commands an excellent market and is so suitable a material in many industrial operations that it cannot be replaced, but its scope would be largely extended if we could render it suitable for those industries which to-day, for certain reasons, prefer to consume raw coal. By reducing the size of the cells present in the coke, by increasing its density and its combustibility, and by reducing the percentage of incombustible matter left in the ash, a solid fuel will be produced which will be of greater value to the industrialist than coal, because, in such a material, the therm will be generated with greater efficiency and with smaller expenditure on labour. Moreover, it is to be foreseen that, if briquetting becomes expedient, then the blending of coals prior to carbonisation will become possible. If this be done, an additional attribute of considerable value will be given to the solid fuel, for the production of a fuel of constant quality will effect an appreciable reduction in labour and control costs. The difficulties experienced in the working of gasworks plant owing to the varying quality of the coal employed are well-known. One of the distinct advantages of coal-gas is its constancy of quality, and the author now wishes to advocate that the gas industry should in the future undertake the responsibility of producing a solid fuel which is also of constant quality.

The whole organisation for dealing with the products of the distillation of coal—*i.e.*, gas, tar, ammonia and coke—exists in the gas industry, and it is to the gas industry that the nation should look for the manufacture of a solid fuel which shall completely displace the use of raw coal both in industrial and domestic appliances. It is required that our solid fuel business should extend in such a manner and with such an increased revenue per therm, that it will reduce the selling price of the gas therm, and so cause gas to be even more generally applicable than it is to-day. There is a strong public movement to achieve the smokeless city and our responsibility in the future must also extend to the supply of solid household fuel for the open fire. If we fail to undertake this responsibility, others will step in and succeed, and in the future we may regret having missed an excellent opportunity of expanding our business. The author is not advocating low temperature carbonisation, for he does not think that in the distillation of coal at low temperatures lies the solution of the household fuel problem. The low temperature process labours under all the disabilities incurred by the production of a plastic layer during the carbonising process. Not only is the distillation process a slow one, but in consequence of the production of the plastic layer, the resulting fuel is large celled and friable (unless special precautions be taken) while the binding material remaining in the coke is high. The distillation process is carried on until the coal charge has been brought into equilibrium conditions at approximately 600°C., and, as a result, some 6 to 10% of volatile matter remains equally distributed throughout the mass. Were the process arrested before equilibrium was attained, an uncarbonised core would result and the fuel would cease to be smokeless. It has already been indicated that in the case of coal-coke briquettes, the absence of the plastic layer allows heat to be transmitted so rapidly through the mass that, after the first three hours, the volatile matter is equally distributed throughout the coke.

Reference to the curves in Fig. 27 will show that if the charge had been withdrawn at the end of the first 3½ hours, 76% of the gaseous therms would have been evolved, and there would have remained 5.6% of volatile matter (17 therms) well distributed throughout the solid fuel. It is thus possible to arrest the high temperature distillation of briquettes after 3½ hours and find 5.6% of volatile matter equally distributed throughout each individual briquette, and this applies, in practice, to briquettes in the centre as well as at the periphery of the retort. This is an important observation, for low temperature carbonising effects as regards the resulting fuel may thus be obtained under high temperature conditions, with a throughput of coal and yield of gas and tar which are very high. The resulting fuel will constitute an excellent substitute for raw coal in the household fire. It will, in fact, be greatly preferred owing to its ease of combustion and its high radiation effect. It possesses, however, one great disability, which must receive careful attention and that relates to its ash content. In order to obtain excellent results in the household fire, the ash content of this solid fuel should not surpass 5 to 6%. The question of the advisability of effecting the separation of ash from the original coal will receive consideration later.

In addition to the two main claims of briquette carbonisation there are one or two incidental advantages which arise from practising this method of distillation. In the first place, it is now a practicable proposition to arrest the distillation process when the amount of work being effected is of such a low order and the cost of recovering the remaining gaseous therms so high, that the loss of gas is more than counterbalanced by the saving effected by the increased throughput of coal. Such a procedure would be impracticable if raw coal were undergoing carbonisation at a high temperature, for to arrest the process in this case would result in an unburnt core in the charge and this would create retort-house annoyance in addition to producing a friable coke from a portion of the charge. Further, it may also be of interest to point out that the introduction of briquette carbonisation in the gas industry would increase the range of coals suitable for gasmaking purposes. It will have been seen from the picture already drawn that a coking coal is one which, after the evolution of gas and the formation of large cells, shrinks to such an extent that the whole mass holds together. The subsequent shrinking operation in the case of briquette carbonisation is certainly important in determining the final density of the fuel and its combustibility, but it is not nearly so important as heretofore, and in consequence a much larger range of possible gasmaking coals is open to the gas industry.

The revolution which the introduction o

briquetted material may produce in the carbonisation process in horizontal retorts may, however, be small compared with the probable effect upon vertical retort practice. Carbonisation in vertical retorts possesses some distinct advantages over that in horizontal retorts, but it is essentially a tar-conserving process, and were it not the usual practice to steam the coal charge, the gaseous thermal yield would be relatively low. The increase in the rate of carbonisation which will result from the use of briquettes is likely to cause a higher gaseous thermal yield to be obtained in the vertical retort, and steaming may then only be practised for the production of a scouring gas, and to utilise the sensible heat of the coke charge. But the advantages will not stop here for the admixture of a suitable proportion of coke or non-caking coal will reduce expansion during carbonisation and will prevent hanging up of the charge within the retort. Moreover, the choice of coals to be used in these installations becomes then almost unlimited. Whatever benefits the prevention of expansion and of the formation of the plastic layer in coal may bestow upon those employing horizontal retorts, the introduction of briquettes may constitute the one link necessary to give the vertical retort complete supremacy in carbonising methods.

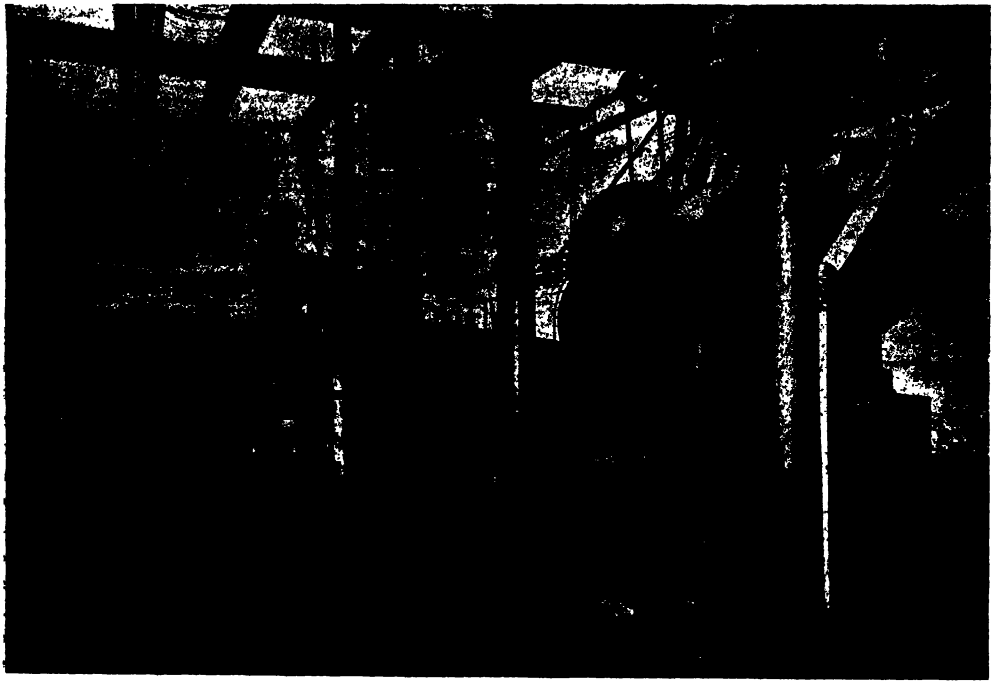

Fig. 32.

The main advantages to be derived from the introduction of briquette carbonisation have now been briefly dealt with and it may be of interest at this point to show the installation for grinding and briquetting which has been used in the preparation of the material for the above experimental trials (see Fig. 32). The engineering problems of briquetting are by no means simple, but E. R. Sutcliffe, who has supplied the necessary plant, has made a study of this problem for many years. On the right of the picture is seen a grinding mill, from which the powdered coal is transported by means of a screw conveyor to the charging hopper of the pressing machine. A briquette weighing some 2 lbs. is made at each stroke of the press and is discharged from the die on to the revolving table. The briquettes are seen lying on the left hand side of the picture.

With regard to the cost of grinding and briquetting, this is estimated by E. R. Sutcliffe and E. C. Evans to be of the order of 3s. 6d. per ton; this figure includes labour, wear and tear, depreciation and interest. The question may be raised as to whether briquetting coal prior to carbonisation is an economically sound proposition and whether the advantages to be derived from this process—namely, enhanced yield of volatile therms, increased throughput and a superior solid fuel—warrant this additional cost. This remains to be determined and several years of experience may be necessary before some of the suggested innovations in carbonisation are realised—if they ever are. It has, however, been necessary to deal in detail with the effect of briquetting in order to present certain aspects of this study of the carbonisation process.

The operation of grinding coal prior to briquetting carries with it several advantages and a few disadvantages. The outstanding disadvantage lies in the fact that coal in a state of fine division is liable to become oxidised, with consequent deterioration in its gasmaking qualities, and thus all plant utilised in grinding and briquetting should be so arranged that only inert gases are brought into contact with the finely divided coal. The author is not sure, in fact, that even this method of operation will entirely prevent some reactions proceeding which may slightly affect the value of the coal as a gasmaking material. Another disadvantage lies in the necessity for taking precautions against fire when dealing with finely powdered coal, although this latter question does not present any material difficulty.

The main advantages of possessing coal in a state of fine division relate to the possibility of chemical treatment being applied prior to carbonisation and to the increased facility with which the operation of de-ashing may be effected. Chemical treatment opens up the wide question of the possibility of hydrogenating the coal substance prior to carbonisation for the purpose of enhancing the yield of volatile products—a question upon which investigators are working at the present time—whilst de-ashing is a problem which is engaging considerable attention in the gas industry to-day. It has already been stated that a process for the removal of ash becomes necessary if we are to aim at the manufacture of a solid household fuel, but the author is not prepared to discuss whether the de-ashing of coal should take place at the colliery or at the gasworks. This question, among others, is determined by geographical position, ease of transit, etc. It is certain that, if the process be carried out at the pithead, the transit of inert material, as well as other labour costs, may be avoided. It will naturally be a question of economics whether or not de-ashing should be practised at the colliery, but it is to be imagined that a large gas undertaking with a favourable solid fuel market and a cheap means of transport is likely to find the de-ashing of coal at the works to be the more remunerative process.

The separation of ash from coal is a problem beset with difficulties, the most formidable of which is that of cost. The processes devised for this purpose fall into three categories :—

(1) Those dependent upon the difference between the density of coal and ash-bearing coal. (The Drescher Table.)

(2) Those based upon the difference in the co-efficient of friction of the coal and ash-bearing coal. (The Spiral Separator.)

(3) Those effecting separation of the ash by taking advantage of the characteristic surface tension effect of certain liquids. (The Minerals Separation, Ltd., Process and the Trent Process).

Most of the known processes have now been studied either directly or indirectly. Each possesses its special attributes and the choice between them largely depends upon the actual requirements of the coal user. Some of these processes effect a very efficient separation of ash and yield tailings containing as much as 70% of ash. Such a degree of separation is inclined to be costly and the author is of the opinion that if de-ashing is to be practised at the gasworks a less perfect process will be preferable. Such a process will be one in which the heads will contain a minimum percentage of ash, while the ash content of the tails will not be too high to prevent their being used in the gas producers required in the gasmaking process. In this way the gasworks would burn its own high ash-bearing coal or coke and at the same time be enabled to manufacture a solid fuel which is capable of becoming a keen competitor to raw coal. In this way, it would be possible to reach the desired goal—namely, the distillation of all raw coal, prior to use, at the gas undertaking of each township.

At this stage it is proposed to summarise the main conclusions which have been arrived at during these lectures and to review some of the earlier statements in the light of the information which has since been presented. The lectures as a whole have dealt with one aspect of the new interpretation of the carbonising process which has arisen from the introduction of the therm system—namely, that the process is in reality one in which the therms of the original coal are distributed into the three forms, gas, tar and coke. No attempt has been made, however, to deal with the important question of heat expenditure during the carbonisation process. In Lecture I, consideration was given to the production of gaseous therms and to means for preventing their wastage in the retort house, while an attempt was also made to indicate the futility of computing the efficiency of a process on the basis of its gaseous thermal yield alone without giving consideration to the two subsidiary products, tar and coke, which are sources of potential therms. This theme was developed in the second lecture when the results of an investigation were submitted which indicated very clearly the inter-relationship existing between coke, tar and gas. These results revealed the fact that by modifying the rate of carbonisation it was possible to convert at will the process of carbonisation into a coke, tar or gas conserving process. Moreover, these results indicated that with very rapid heating, when the process was essentially a gas conserving one, the yield of volatile therms exceeded that normally obtained by 8 to 9 therms. It will be agreed that this observation is one of considerable importance to the gas manufacturer and in this lecture means have been considered for reproducing such results on a large scale. It has been shown that by admixing inert material such as coke with the original coal a rapid rate of heat transmission is attained which results in enhanced yields of volatile therms. Such an innovation in the carbonising process opens up new vistas of possibilities in the development of the gas industry and consideration has been given to some of the radical changes which would be effected both in horizontal and vertical retort practice if briquette carbonisation ever became an accomplished fact. The subject is, however, in its infancy, but it is probably along these lines that future progress in the gas industry may be effected.

It will be seen that the first lecture presented certain facts which may be applied in practice to-day; the second also presented facts but referred to those culled in the laboratory, while the present lecture deals with a few results, and also with a hypothesis which should be treated entirely as such.

All the work has received the inspiration and guidance of my chief, Dr. Carpenter, who more justly should have delivered these Cantor Lectures.

Finally it may be imagined that the large amount of work collected together could only have been carried out with the help of able assistants. It would be difficult to name all who have contributed in their work to the preparation of these lectures. I, therefore, desire to tender my thanks to three senior assistants, Harold Hollings, M.Sc., Harold Stanier, B.A., and Edith Langdon, B.Sc.

PENCIL CEDAR FROM EAST AFRICA.

The timber resources of Kenya Colony have recently been surveyed by the Government and the findings made public. In general it is believed that, for the present, transportation is too little developed in the colony to allow of the profitable exportation of either hewn or sawn timber of ordinary kinds since the regions of supply are hundreds of miles inland. It is thought, however, that certain specialties could be handled with profit at present.

According to the United States official "Commerce Reports," the specialty which will probably first receive the attention of the exploiters is a wood locally known as "mutarawka" (*Juniperus procera*) which it is thought will form a most excellent substitute for the American pencil cedar now in use, which is reported to be rapidly disappearing. Mutarawka is found in the highland forests of the district and is shipped from Mombasa. It is described as a handsome reddish brown softwood with fine even grain which saws, planes, and works up well, is rather brittle, very fissile and, like the original pencil cedar, aromatic. Its chief claim, however, is that it possesses in a high degree that quality indispensable to pencil wood, namely, it whittles well. It is said to be somewhat harder than the *Juniperus virginiana*, but experts believe that the degree of hardness depends very largely upon the age of the tree when cut and the methods of seasoning. The exact quantity of standing timber now available is not yet calculated, but it is estimated that sufficient supplies are available to keep up a sustained export in pencil slats until such time as reforestation, which could be started immediately, would be ready for exploitation. The wood is at present attacked by a fungus, which renders many of the largest and oldest logs subject to internal cavities. This is now being studied with the idea of control and elimination, but for a wood supply to be used for pencils the defect is not considered a serious drawback.

CZECHOSLOVAK FLOUR-MILLING.

Flour mills, naturally of primitive type, are recorded as existing in Bohemia as early as in the 8th century, and windmills are mentioned in chronicles from the commencement of the 11th century onward. By the year 1605, the number of mills in Bohemia driven by water-power alone was 8,500, and this total continued to increase until the introduction of modern machinery, which began about the year 1846. From the time that the milling process began to be industrialised, the mills have declined in number, but those surviving have, of course, increased in size and output.

The 6,940 mills existing, for example, in Bohemia in the year 1875 had declined by the year 1902 to 5,547. At the present moment there are, throughout the whole of Czechoslovakia, 10,715 flour mills, which normally give employment to about 30,000 workpeople. Of these mills, 5,276 are in Bohemia, 2,100 in Moravia, 337 in Silesia, 2,500 in Slovakia, and 502 in Carpathian Ruthenia.

The normal output of the flour mills of Czechoslovakia is placed at, roughly, 5,187,000 tons per annum. On the other hand, the total consumption of the country (for a population of approximately 14,000,000) is about 3,180,000 tons. Wheat and rye, however, are grown in Czechoslovakia to the extent of only 2,100,000 tons annually, so that considerable imports are necessary, and these may, of course, take the form of either grain or flour.

Unfortunately for the Czechoslovak flour-milling industry, the imports of milled products are greatly in excess of those of grain. In 1923, some 220,000 tons of flour were imported, as compared with only 14,000 tons of wheat and rye grain, and in the first three months of the current year, although grain imports have risen to 35,130 tons, compared with 2,517 tons for the same period last year, the flour imports have also risen, totalling 67,265 tons, as against 48,971 tons in the first three months of 1923.

The main imports affecting the milling industry came last year from the following countries:

	Wheaten flour.	Wheat and Rye grain.
	(Value of imports in Czechoslovak crowns.)	
Germany	176,523,059	5,636,040
Hungary	120,506,586	1,966,931
U.S.A.	87,728,297	2,510,334
France	56,455,286	—
Hamburg	49,734,451	—
Austria	46,879,196	6,786,271
Holland	29,806,056	131,803
Great Britain	9,297,796	—
Yugoslavia	2,509,911	8,425,188
Rumania	2,509,294	146,648
Brazil	—	390,170
Canada	—	325,910
Argentine	—	271,102
Other countries	20,337,562	9,309,432

The Federation of the Czechoslovak Millers have made repeated efforts to convince the authorities of the necessity for measures to protect the milling industry. These efforts have not yet met with success and the situation of the mills remains precarious.

Many of the flour mills utilise the flour they mill in their own bakeries, turning out bread, etc., in considerable quantities. One concern of this kind bakes 80,000 loaves per day besides some 150,000 cakes, rusks, etc.

The modern machinery and equipment of the flour mills is entirely made in Czechoslovakia, several of the leading engineering works specialising in this and other mill and factory plant.

CZECHOSLOVAK EXPORTS AND IMPORTS.

The value of Czechoslovakia's imports in June was Kc 1,230,125,178, compared with Kc 1,575,688,150 in the previous month—a reduction of some 345 millions. Exports for June were also lower than the May figure. There was a favourable balance of trade in June of 96 million crowns, while for the first six months of the year the favourable balance was as follows:—

Jan.-June:	Weight in tons.	Value in Czechoslovak crowns:
Exports	6,208,876	Kc 7,831,662,228
Imports	2,267,044	7,263,321,362
	3,941,832	568,340,866

There is thus a favourable balance of over 568 million crowns for the first six months of the current year. Last year the figure was 1,540 millions, and the difference is due to this year's largely increased imports. At the same time the bulk of trade altogether shows a very satisfactory increase, the comparative figures for the two years being:

	1924	1923
Exports	Kc 7,831,662,228	Kc 5,619,107,552
Imports	7,263,321,362	4,072,939,832

The bulk of trade has, therefore, increased by over 50% compared with 1923. The main items of import in June were (in millions of Czechoslovak crowns):

Raw cotton and yarns	236
Grain, flour, pulse	235
Wool, woollen yarns	153
Fats	61
Cattle	42
Fruit vegetables	40
Silk and silk goods	38
Minerals	36

Other imports in June included iron and hardware (33 million crowns), animal products (32 millions), timber and coal (3), flax, hemp and jute (29), common metals (29), tobacco* (22), chemicals (21), waste (17), mineral oils (17), leather (16), Italian wares (13), paints, colours, perfumery (11), rubber and caoutchouc (11), instruments, clocks and watches (10).

Practically all imports show an increase compared with last year, only the item of fats having declined considerably.

The following table shows the imports from the various countries :—

(in millions of Czechoslovak crowns).

	June	June	January to	June
	1924	1923	1924	1924
Germany	433	345	2513	1674
Austria	101	50	570	254
Italy	92	34	591	178
Hungary	77	18	324	130
U.S.A.	62	48	460	314
England	49	31	210	146
Poland	47	16	256	119
Holland	35	34	182	187
France	33	33	263	143
Rumania	32	7	204	67
Switzerland	30	19	194	87
Yugoslavia	20	15	150	114
Belgium	7	6	58	34
Other countries	211	105	1289	623

Imports in June from the United States declined as compared with the figure of 111 million crowns' worth in May. Imports from England, on the other hand, improved from 44 millions in May to 49 in June, the latter figure being well over the monthly average. Last year America was third on the list of countries from which Czechoslovakia gets her imports ; this year she is fourth. England which, early this year, dropped low on the list has risen to seventh.

INDUSTRY IN TURKEY.

Turkey has never been an industrial country. Few factories existed in pre-war days, factory industry being far less important than domestic handicraft. In districts served by railways, domestic handicraft has also declined, peasants finding it more profitable to export their raw materials and buying foreign goods brought within their reach by railway transport.

Industry and domestic handicraft have suffered considerably through military operations, terminating with the Greek debacle and the partial destruction of Smyrna's industrial and commercial centres, as well as those in other localities, of the vilayets of Aidin and Hudavindikiar (Broussa) during the Greek retreat and the Turkish advance. Lack of skilled labour, due to the exodus of the Christian element, is considerably prejudicing the remaining industries in these localities.

In his Report on the Economic and Commercial Conditions in Turkey, the Commercial Secretary at Constantinople remarks that it is not possible at this juncture to form a correct estimate of the ravages caused by the unfortunate campaign in Anatolia. Previous to the war no statistics of Turkey's factory industry and handicraft were ever published.

Statistics were prepared in 1921 by the Government of Angora, but they only covered areas under its direct administration, which did not constitute the richer industrial centres, such as those of the vilayets of Smyrna, Hudavindikiar (Broussa), at that time in Greek occupation, as well as Constantinople, then occupied by the Allies. These statistics are interesting however, as showing how unimportant Turkey's factory industry and domestic handicraft were in 1921 in the areas controlled by Angora's administration.

The richer industrial centres have suffered very heavily, especially those in Smyrna and neighbourhood, in the Broussa district, and in some regions situated in the Asiatic littoral of the Sea of Marmora. The following is an estimate of the value of the output of some of the industries and handicraft furnished in the statistics referred to above :—

	Value of output. Piastres.
Tinware	1,150,000
Copperware	3,127,000
Cutlersware	1,476,000
Sawmills	818,000
Ironware	1,318,000
Armourers	436,000
Cast metalware	337,000
Native stoves	2,476,000
Cartwrights and manufacturers of agricultural machinery	64,762,000
Jewellers	1,455,000
Stone and earthenware	114,182,000
Carpentry	9,264,000
Woodturning	2,481,000
Saddlers	9,852,000
Confectionery	14,667,000
Preserved meats, etc.	30,468,000
Flour mills	214,530,000
Macaroni factories	3,426,000
Olive oil factories	11,607,000
Total	487,832,000

GENERAL NOTE.

◆

Census of French Sawmills.—A census of the number of sawmills, both fixed and portable, existing in France, was taken recently by the Administration des Eaux et Forêts. According to a report furnished by the United States Assistant Commercial Attaché in Paris, the total is 10,835, of which 1,471 are portable. The daily capacity of output is 29,468,000 feet, of which 3,392,000 feet constitute the output of the portable mills. The Bordeaux District, with 892 sawmills and a daily productive capacity of 3,445,848 feet, is the most important. Other districts where the daily productive capacity is over 848,000 feet are Paris, Rouen, Chambery, Amiens, Epinal, Alençon, Tours, Moulins, Niort, Aurillac, and Strasburg. Of the sawmills, 8,695 have a daily output of less than 4,240 feet, although their total capacity output is 13,313,600 feet.

Journal of the Royal Society of Arts.

No. 3,752. VOL. LXXII.

FRIDAY, OCTOBER 17, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICES.

OPENING OF THE 171st SESSION.

The Opening Meeting of the 171st Session will be held on Wednesday, November 5th, when an address will be delivered by Senatore Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., Chairman of the Council. The chair will be taken at 8 p.m.

DOMINIONS AND COLONIES SECTION.

A meeting of the Dominions and Colonies Section Committee was held on Friday, October 10th. Present—Lord Blyth (Chairman of the Committee) in the chair, Sir Charles H. Bedford, D.C.L., LL.D., D.Sc., M.D., Mr. Byron Brenan, C.M.G., Hon. Sir John A. Cockburn, K.C.M.G., Hon. H. P. Colebatch (Agent-General for Western Australia), Mr. Edward Dent, M.A., Hon. G. Fairbairn (Agent-General for Victoria), Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S., and Sir Charles Metcalfe, Bt., with Mr. G. K. Menzies, M.A. (Secretary of the Society), and Mr. S. Digby, C.I.E. (Secretary of the Dominions and Colonies and Indian Sections).

REPRINT OF COBB LECTURES.

The Cobb Lectures on "Certain Fundamental Problems in Photography" by T. Slater Price, O.B.E., D.Sc., F.I.C., F.R.S., Director of Research to the British Photographic Research Association, have been reprinted from the *Journal*, and the pamphlet (price 3*s*.) can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2.

A full list of the lectures which have been published separately and are still on sale can also be obtained on application.

REPORT ON THE SOCIETY'S EXAMINATIONS, 1924.

The Council have much satisfaction in reporting that the total number of candidates entering for the Society's examinations in 1924 again constitutes a record. The figure this year is 67,282, as compared with 64,518 in 1923, which was up till then a record. The curve on page 828 shows how the numbers have grown since the year 1900.

The remarkable increase seems amply to justify the policy adopted by the Council in regard to the conduct of the examinations. They appointed a very strong Committee, which includes representatives of the Board of Education, the London County Council, various other local education authorities, and several important commercial schools. In this way the Council are kept extremely well informed of the needs of students, and they are able to modify or add to the examination syllabuses as occasion may arise. This year, for instance, three new subjects were added, viz., Foreign Exchange, Stock Exchange Law and Practice, and Advertising and Salesmanship; next year Costing will be included; and the Council will always be ready to make further additions as soon as they are assured that there is a genuine need for them.

In order to encourage students to take up group courses of subjects, the Council have decided to offer prizes to the value of £200 in 1925. Fourteen prizes of £10 each will be offered to candidates who are awarded group certificates in commercial subjects in Stage III., and twelve prizes of £5 each will be offered to candidates who are awarded group certificates in Stage II. The regulations relating to these group certificates will be found on page 13 of the Syllabus of Examinations, 1925.

The value of the certificates is becoming more and more widely recognised every year. Many important business and industrial firms encourage their employees to enter for these examinations, and some grade their junior staffs according to the successes which they obtain.

The Examinations were held, as usual, at two periods, April and May-June. In April the number of entries was 27,273, and in May-June, 43,805. The papers worked were divided between the two Examinations as follows :—

	April.	May-June.	Total.
Advanced Stage	2,731	6,345	9,076
Intermediate Stage ..	8,2061	6,808	25,014
Elementary Stage ..	16,336	20,655	36,991

In addition to the 67,282 papers worked in the written examinations, 795 candidates presented themselves for the *viva voce* Examinations in Modern Languages.

The subjects of Examination this year were :—

Arithmetic.
English.
Book-keeping.
Shorthand.
Typewriting.
Economic Geography.
Economic and Social History.
Economic Theory.
Précis-writing.
Commercial Correspondence and Business Knowledge.
Commercial Law.
Company Law.
Accounting.
Banking.
Foreign Exchange.
Theory and Practice of Commerce.
Railway Law and Practice.
Railway Economics.
Shipping Law and Practice.
Stock Exchange Law and Practice.
Insurance Law and Practice.
Advertising and Salesmanship.
French.
German.
Italian.
Spanish.
Russian.
Danish and Norwegian.
Dutch.
Swedish.

Arithmetic.—The total number of papers worked in all three stages was 7,465, as compared with 6,568 in 1923. In Stage III. the number of candidates was 291, of whom 30 obtained first-class certificates, 111 obtained second-class certificates, and 150 failed. The proportion of failures is a good deal higher than it ought to be ; the examiner still finds it necessary to draw attention to great weakness in mensuration and the use of Logarithms, and the application of compound interest to annuities and kindred problems.

In Stage II there were 1,760 candidates, of whom 296 obtained first-class certificates, 883 obtained second-class certificates, and 581 failed. A large proportion of the candidates had evidently not been properly prepared in the subjects of the syllabus, while many failures were due not so much to inaccuracy of calculation as to want of intelligence in reading the questions and grasping their meaning.

In Stage I, out of 5,414 candidates, 3,810 passed and 1,604 failed. It is satisfactory to note that the examiner reports a general improvement in the style of the working, but again he has to draw attention to the lack of common sense on the part of some candidates. Thus, in one paper the cost of gravel for a garden path was given as £1,131,642,159 12*s.* 8*d.*, while in another the number of paupers on every 1,000 acres was given as 27,173,898,380,190.

English.—The importance of English as the basis of any sound education in this country can hardly be over-estimated. Over and over again have examiners in almost all subjects of the Society's examinations drawn attention to the fact that candidates are very deficient in the power of expressing themselves, and that even in the higher stages many make the most elementary mistakes in spelling, grammar and composition. There is some satisfaction in noting that the number of those entering for the examination in English is steadily growing. This year the total was 5,690, as compared with 4,997 in 1923, and 3,790 in 1922 ; but the quality of much of the work submitted was very poor, and in view of the large number of candidates in all subjects, 67,282, one cannot but feel that the proportion of those taking English ought to be very much larger than it is.

In Stage III there were 337 candidates, of whom only 20 obtained first-class certificates, 160 obtained second-class certificates, and 157 failed. While much of the work submitted was fairly good, very little of it was really excellent. Many of the candidates would have done well in Stage II, but fell short of the requirements of Stage III, where both the standard and the passmark are very considerably higher. The examiner comments on the tendency of students to use such worn out phrases as "wend our way," "feathered tribe," etc. Teachers cannot impress upon their pupils too strongly the value of a simple and direct style, free from the "flowery" and the meretricious.

In Stage II there were 1,505 candidates, of whom 93 obtained first-class certificates, 984 obtained second-class certificates, and 428 failed. As in Stage III, the proportion of first-class work is disappointingly small, and here again the examiner has to complain that the style of many of the essay-writers suffers from the same faults as those commented on in Stage III.

In Stage I there were 3,848 candidates, of whom 2,127 passed and 1,721 failed. The total number of entries shows an increase of exactly 600 over the corresponding figure for last year, but unfortunately, it seems to be the bad centres which contribute most to the increase. A good many of these candidates are a good deal below any reasonable standard of examination, as will be seen from some of the specimens of answers quoted by the examiner in his report.

Book-keeping.—This continues to be far and away the most popular subject of examination, the total number of entries being 20,409. In Stage III there were 3,448 candidates, of whom 422 obtained first-class certificates, 1,496 obtained second-class certificates, and 1,530 failed. The leading papers were exceptionally good. Some candidates possessed little or no knowledge of the forms of various registers in the case of limited companies, and many were at fault in their treatment of debentures issued as collateral security for a loan, while in numerous cases neatness was wanting in the worked exercise.

In Stage II there were 7,375 candidates of whom 866 obtained first-class certificates, 4,541 obtained second-class certificates, and 1,968 failed. It is very satisfactory to note that the examiner reports a distinct improvement this year in the standard of first-class papers.

In Stage I there were 9,594 candidates, of whom 5,890 passed and 3,704 failed. Here, too, there is a distinct improvement in the work submitted by candidates as compared with former years. The examiner, in his report, draws attention to a number of points in which candidates showed weakness, and teachers would do well to study these comments and to bring them to the notice of their students.

Shorthand.—The number of entries in this subject has again increased, the total figure being 13,518, as compared with 12,679 in 1923, and 11,229 in 1922. In Stage III. there were 1,273 candidates; 88 passed the test at 140 words per minute; 180 at 120 words a minute, and 1,005 failed. These results are extremely disappointing, and the examiner has taken a great deal of trouble to ascertain the causes of the heavy percentage of failures. He finds that the average age of candidates entering for Stage III. in shorthand is lower than that of those entering for the same stage in other subjects, and consequently their knowledge of English cannot be expected to be so good as that of candidates whose studies have extended over a longer period. Further, there are evidences that many of the candidates have attempted to acquire speed too quickly, a practice far too common now-a-days; while in many cases candidates, instead of being content to complete one of the passages and to do it well, attempted both passages and finished neither.

In Stage II. there were 6,132 candidates, of whom 1,111 passed the test at 100 words per minute, 2,676 at 80 words per minute, and 2,345 failed. The work submitted was very fair, and the spelling on the whole was good. The word "pneumatics" seemed to be quite unknown to many candidates, one of whom transcribed it as "auctomatacus."

In Stage I. there were 6,113 candidates; 2,471 passed the test at 60 words per minute, 2,022 at 50 words per minute, and 1,620 failed. The results here were very satisfactory, and there was a noticeable improvement in the spelling.

Typewriting.—It is very regrettable that the examiner should have to comment on the bad spelling of candidates in all stages of the typewriting examination. A typist who cannot spell correctly is of little use to anyone, and this brings us back once more to the point on which we have had to insist so often in former years, that a sound knowledge of English is essential as a preliminary basis for preparation for any subject of study in this country. In Stage III, at all events, where a first-class certificate is recognised by many educational authorities as a Teachers' qualification, serious misspellings should be unthinkable. Apart from this failing, the work appears to have been on the whole quite excellent.

In Stage III there were 596 candidates of whom 120 obtained first-class certificates, 360 obtained second-class certificates, and 116 failed. In Stage II there were 2,356 candidates, of whom 1,055 obtained first-class certificates, 1,070 obtained second-class certificates, and 231 failed. The papers worked in this stage were particularly good, as the results show; and quite a large number of candidates made over 90 per cent. of the marks.

In Stage I there were 3,524 candidates, of whom 2,482 passed and 1,042 failed. The examiner in his report quotes a number of misspellings which are deplorable. The exercise of the least grain of commonsense would have saved the candidate from stating that the training ship *Exmouth* was "dry-docked and her boots cleaned."

Economic Geography.—In Stage III there were 49 candidates (as against 33 last year), of whom 4 obtained first-class certificates, 31 obtained second-class certificates, and 14 failed. The examiner reports that this year there is a real change of standard, the work being altogether better than on previous occasions. Apparently, however, teachers have not yet learnt the necessity of instructing their pupils as to the really important features of relief maps.

In Stage II there were 158 candidates. Unfortunately, the examiner was not able to award a single first-class certificate, 94 candidates obtained second-class certificates, and 64 failed. The quality of the papers worked in this stage is as discouraging as that of the Advanced Stage is encouraging. Over 60 per cent. of the candidates only secured from 40 to 50 marks, while two or three failed to obtain 8 per cent. of full marks.

In Stage I there were 292 candidates, of whom 185 passed and 107 failed. On the whole the general standard of the work seems to be steadily improving, but the examiner draws attention to the tendency of candidates to misread the questions. This gives evidence of insufficient training in regular examination work; for no candidates doing regular examination work and being properly penalised for careless reading of the questions set could make the mistakes shown in these papers as a whole. It is earnestly hoped that teachers will make a note of this point.

Economic and Social History.—There is a satisfactory increase in the number of candidates taking this subject, the figure being 146, as compared with 48 last year. In Stage III there were 17 candidates. Only one failed, but on the other hand only one obtained a first-class certificate. The general level of the work was satisfactory, and gave evidence of careful and intelligent study. In Stage II there were 44 candidates, of whom 5 obtained first-class certificates, 22 obtained second-class certificates, and 17 failed. The papers varied widely in quality, the best being of considerable excellence, and the worst bad failures. In Stage I there were 85 candidates, of whom 49 passed and 36 failed. None of the work submitted reached a very high standard.

Economic Theory.—The total number of entries in this subject was 378, as compared with 355 in 1923. In Stage III there were 150 candidates, of whom 17 obtained first-class certificates, 90 obtained second-class certificates, and 43 failed. A considerable number of the papers were creditable, and some remarkably good. In Stage II there were 228 candidates, of whom 12 obtained first-class certificates, 155 obtained second-class certificates, and 61 failed. While some of the questions were answered well, there were very few papers in which a high level was maintained throughout.

Précis-writing.—The number of candidates taking this subject continues to be small, indeed, there is a slight decrease as compared with last year, the respective figures being 101 and 113. On the other hand, the examiner reports a continuance of the general improvement in the standard of work which he noticed in 1923. In Stage III there were 46 candidates, of whom 6 obtained first-class certificates, 30 obtained second-class certificates, and 10 failed. In Stage II there were 55 candidates, of whom 10 obtained first-class certificates, 31 obtained second-class certificates, and 14 failed.

Commercial Correspondence and Business Knowledge.—The total number of entries in this subject was 3,996. In Stage III there were 101 candidates, of whom 8 obtained first-class certificates, 42 obtained second-class certificates, and 51 failed. In Stage II there were 951 candidates, of whom 72 obtained first-class certificates, 708 obtained second-class certificates, and 171 failed. In Stage I of 2,944 candidates, 1,931 passed and 1,013 failed.

Commercial Law.—433 candidates entered in this subject. In Stage III there were 162, of whom 45 obtained first-class certificates, 80 obtained second-class certificates, and 37 failed. There were several brilliant papers, but, speaking generally, candidates were not well grounded in the law of bankruptcy, and a more detailed and exact knowledge of this branch of the syllabus will be expected in future. In Stage II there were 271 candidates, of whom 71 obtained first-class certificates, 159 obtained second-class certificates and 41 failed. The examiner reports that the work was not up to the usual high standard shown by candidates in this examination, the two commonest faults being inaccuracy and irrelevance.

Company Law.—The total number of entries in this subject was 308. In Stage III there were 111 candidates, of whom 20 obtained first-class certificates, 64 obtained second-class certificates, and 27 failed. A number of excellent papers were worked which showed not only a grasp of fundamental principles, but a knowledge of detail and a familiarity with leading cases. Most of those who failed would have been better advised to attempt the Intermediate examination. In Stage II there were 197 candidates, of whom 67 obtained first-class certificates, 123 obtained second-class certificates and only 7 failed. Most of the papers showed an intelligent knowledge of the elementary principles of Common Law, and gave evidence of skilful teaching combined with careful study. It is curious that the examiner finds it necessary again to comment on the erroneous statement of a candidate, which was referred to in his report last year, that the Royal Society of Arts is a trading company which has obtained permission of the Board of Trade to omit the word "limited" as the last part of its name. How the statement came to be made in the first place is difficult to understand; how it came to be repeated is incomprehensible.

Accounting.—The number of candidates in this subject was 623, of whom 70 obtained first-class certificates, 284 obtained second-class certificates, and 269 failed. The work submitted was of average merit. Many candidates showed a lack of knowledge of costing: this is a subject of great and growing importance, and it is hoped that its addition as a special subject of examination in next year's syllabus will lead to its receiving more careful attention in future.

Banking.—Only 31 candidates entered for this subject, of whom 5 obtained first-clas certificates, 10 obtained second-class certificates, and 16 failed. The examiner complains that, as was the case last year, candidates showed lack of knowledge of bank book-keeping.

Foreign Exchange.—This subject, introduced for the first time this year, attracted 25 entries in all. In Stage III there were 11 candidates, of whom 1 obtained a first-class certificate, 8 obtained second-class certificates and 2 failed. In Stage II, of 14 candidates, 4 obtained first-class certificates, 7 obtained second-class certificates, and 3 failed. Once more the examiner has to complain of the very defective command of English possessed by the candidates generally.

Theory and Practice of Commerce.—The total number of entries in this subject has risen from 768 in 1923 to 1,040 this year. 182 candidates entered in Stage III, of whom 23 obtained first-class certificates, 90 obtained second-class certificates, and 69 failed. In Stage II there were 479 candidates, of whom 24 obtained first-class certificates, 293 obtained second-class certificates, and 162 failed. In Stage 1, of 379 candidates, 254 passed and 125 failed. In last year's report it was mentioned that entirely new syllabuses had been prepared in all three stages of this examination, and it is satisfactory to note that the results this year have been far more normal than was the case in 1923. There would still appear to be difficulties in finding sufficient suitable teachers of this subject, but the Examinations Committee has brought this fact to the notice of the London County Council, and it is hoped that means may be found to provide special training for this purpose.

Railway Law and Practice.—The examiner again reports an improvement in the quality of the work submitted in this subject, but unfortunately, the number of entries continues to fall, being 58 as against 107 in 1923, and 207 in 1924. Of these, 11 obtained first-class certificates, 32 obtained second-class certificates, and 15 failed. In view of the very large staffs attached to the many railway companies of the country, this decrease is distinctly disappointing. While the candidates generally have shown a sound knowledge of the law, many of them appear to be using out-of-date editions of text-books.

Railway Economics. — 29 candidates entered this subject, of whom 6 obtained first-class certificates, 15 obtained second-class certificates, and 8 failed. For the most part they appeared to be well grounded in the subject, but the number in the first-class would have been considerably greater had the candidates been more careful to write exactly on the points mentioned in the questions.

Shipping Law and Practice.—The number of candidates this year was 33, as against 21 last year, but this is still a very exiguous figure compared to the great size and importance of the shipping industry. 5 candidates obtained first-class certificates, 15 obtained second-class certificates, and 13 failed. Many of the entrants showed distinct ability in dealing with the problems and cases set in the question paper, but there was a general weakness in explaining legal terms.

Stock Exchange Law and Practice.—The examination in this subject, held for the first time this year, attracted 45 candidates. In Stage III there were 23, of whom 3 obtained first-class certificates, 13 obtained second-class certificates, and 7 failed. In Stage II 8 obtained first-class certificates, 8 obtained second-class certificates, and 6 failed. The examiner reports that on the whole the papers in both stages were very fairly done, but a number of candidates did not possess sufficient command of English to express themselves properly.

Insurance Law and Practice.—Of the 19 candidates in this subject, 4 obtained first-class certificates, 13 obtained second-class certificates, and 2 failed. The results are satisfactory, though not quite as good as in 1923, when there were 25 candidates. Very few were able to define insurable interest, or to give a concise statement of the law as to disclosure of material facts.

Advertising and Salesmanship.—This subject, introduced into the syllabus for the first time this year, attracted 41 candidates, of whom 7 obtained first-class certificates, 28 obtained second-class certificates, and 6 failed. With few exceptions the work submitted gave evidence of careful preparation, intelligent study, and sound knowledge of the theory of advertising. Some of the answers were exceedingly good.

MODERN LANGUAGES.

French.—The total number of candidates in French this year was 4,808. In Stage III there were 612 candidates, of whom 77 obtained first-class certificates, 293 obtained second-class certificates, and 242 failed. Some excellent work was submitted: indeed, the examiner reports that among the April papers was some of the best work he has ever had the pleasure of examining in a long experience: one of them was practically flawless, and secured full marks—a very rare thing. The number of first-class candidates would have been considerably higher but for weakness in syntax shown by otherwise good students.

In Stage II there were 1,799 candidates, of whom 119 obtained first-class certificates, 1,020 obtained second-class certificates, and 660 failed. The work shows that French is being carefully taught by a large number of skilful teachers with very satisfactory results.

The Examiner in Stages III and II has been at considerable pains to draw up a long statement containing advice, based on wide experience, as to the best means of studying French. This contains some exceedingly practical and valuable hints, and it is earnestly hoped that all students entering for the Society's examinations in French will carefully digest them and cultivate some of the admirable practices which he suggests.

In Stage I there were 2,397 candidates, of whom 1,879 passed and 518 failed. The general results were satisfactory, and it is gratifying to know that the grammatical questions were answered better than in previous years.

German.—In Stage III there were 58 candidates, of whom 24 obtained first-class certificates, 21 obtained second-class certificates, and 13 failed. In Stage II there were 136 candidates, of whom 18 obtained first-class certificates, 73 obtained second-class certificates, and 45 failed. In Stage I, of 141 candidates, 80 passed and 61 failed. Unfortunately, the standard of work generally was not high, great weakness being shown in elementary syntax and grammar, even in the advanced stage; but happily, there was a marked improvement in this respect among the candidates for the Stage I examination in April.

Italian.—In Stage III there were 17 candidates; 2 obtained first-class certificates, 13 obtained second-class certificates, and 2 failed. In Stage II, of 25 candidates, 1 obtained a first-class certificate, 17 obtained second-class certificates, and 7 failed. In Stage I there were 56 entries; 36 candidates passed and 20 failed.

Spanish.—The total number of candidates taking this subject was 638. In Stage III there were 99, of whom 11 obtained first-class certificates, 67 obtained second-class certificates, and 21 failed. As a result of this examination the examiner concludes that the student who devotes his attention to learning the language thoroughly without limiting himself to what he considers its purely commercial aspect, makes much more rapid progress. "Whereas the literary candidates display a sound knowledge of grammar and a good acquaintance with modern authors—in some cases of more extended periods of literature and history—the commercial candidates are distinctly inferior, and show the weakness of their acquirements by inventing words and making use of French or Italian expressions or terms of speech."

In Stage II, of 242 candidates, 27 obtained first-class certificates, 183 obtained second-class certificates, and 32 failed. The composition and essays showed a fair amount of promise, but weakness in grammar accounted for the small number of first-class awards.

In Stage I 244 candidates passed and 53 failed. The general average of the work submitted was very satisfactory, but the examiner still considers that there is a lack of adequate verb drill.

Russian.—This subject shows no sign of recovering the popularity which it enjoyed when the "Russian steam-roller" was expected to flatten out our enemies before it. In 1917 there were 266 entries; this year there were only 22. In Stage III, of 3 candidates, one obtained a first-class and 2 obtained second-class certificates. The work of the first candidate, who secured the Russian Embassy Prize, is described by the examiner as "almost perfect." In Stage II there were 7 candidates, of whom 4 obtained first-class certificates, 2 obtained second-class certificates, and 1 failed. The work done here was very satisfactory. In Stage I, of 12 candidates, 9 passed and 3 failed. The answers were of very moderate quality and show that candidates are apt to enter for this examination at too early a stage in their preparation.

Danish and Norwegian, Dutch, and Swedish.—For several years examinations have not been held in these languages, but as a certain number of students were anxious to enter this year, it was decided not to disappoint them. Unless, however, the numbers increase, it will not be possible to hold examinations in future years, except perhaps at rare intervals. In Danish and Norwegian there were 10 candidates. In Stage III 2 entered, of whom one obtained a first-class certificate, and one failed. In Stage II 8 entered, of whom 5 obtained first-class, and 3 second-class certificates. In Dutch, 4 candidates entered for Stage II, 2 obtained second-class certificates and 2 failed. In Swedish also, 4 candidates entered for Stage II, of whom one obtained a first-class, 2 obtained second-class certificates, and one failed.

ORAL EXAMINATIONS.

The results of the Oral Test which is now compulsory for all Candidates in the Advanced Stage of French, German, Spanish and Italian were not so good as last year; although there were 99 less candidates than in 1923, there were 53 more failures this year. An important part of the Oral Test is the taking down of a passage dictated in the foreign language by the examiner, and in the past this has been a source of great weakness with many candidates. It is gratifying to be able to state that the examiners now report a very great improvement in this branch of the examination.

COMMERCIAL KNOWLEDGE CERTIFICATES.

The increase, noted in last year's report in the number of Candidates entered from Higher Elementary Schools, and also the new Central Day Schools set up under various Education Authorities, has been well maintained. Most of these Candidates take a group of subjects qualifying for the Certificate in Elementary Commercial Knowledge. To gain this special Certificate Candidates must pass in Arithmetic, Book-keeping, English and one other subject within three consecutive years, but it is satisfactory to find that many pupils from Day Schools pass in the necessary subjects in one year. In view of the fact that a fairly high standard is maintained in the Elementary Stage (it is by no means a first year's examination) the results at these Schools give evidence of really excellent preparation.

The thanks of the Council are once more accorded to the Court of the Clothworkers' Company, who have generously renewed their grant of £40, towards providing medals in all the subjects of examination where the work of candidates attains a sufficiently high standard. There is no doubt that there is very keen competition for these medals, and that they have done much to maintain or raise the level of excellence in the papers worked.

The Examination Syllabus for 1925* has been issued. In it will be found the fullest possible information about the examinations, a syllabus of each stage of each subject, and list of centres. The papers set in 1924 have been reprinted in six pamphlets. Each pamphlet contains in addition to the papers of each stage, the syllabuses of the subjects in the pamphlet and the Examiners' reports on the papers worked. Both teachers and students are strongly advised to study not only the syllabuses, but also the remarks of the various examiners on the results of last year. It will be found that these contain many valuable and helpful suggestions, and the work of the candidates year after year shows that far too little attention is paid to them.

The regulations for the Oral Examinations in Modern Languages are also given at full length in the syllabus.

---

* The price of the Syllabus for 1925 is 4*d*., post free. Copies can be obtained on application to the Examinations Officer, Royal Society of Arts, Adelphi, London W.C.(2). The price of the pamphlets containing the 1924 papers is 4*d*. each, post free. Particulars of these may be obtained as above.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

COLLOID CHEMISTRY.

By ERIC K. RIDEAL, M.B.E., Ph.D., D.Sc., F.I.C.

LECTURE I.—*Delivered January 21st*, 1924.

The growth of what is generally termed civilisation is dependent in great measure on the increase in knowledge of the properties and uses of the materials and forces placed at our disposal in the universe. The periods of development may roughly be divided into five: the prehistoric, stone, bronze, iron and the present. If we examine the complicated mosaic which constitutes our age we note that the subject of colloidal phenomena and properties of colloids is becoming increasingly important. It would take too long a time to enumerate the various directions into which the subject matter intrudes, but its significance will be understood when we remember that the animal and vegetable and many mineral products, which in major part form our bodies, clothes and food and fuel, are endowed with and operate in great measure under the influence of those forces which are the *raison d'être* of colloidal phenomena.

The term colloid was introduced in 1861 by Thomas Graham, who distinguished colloidal substances from crystalline materials by the relatively rapid rate of diffusion of the latter class of substances, and he believed that the distinction between a crystalloid and a colloid was a fundamental one. It has, however, been shown that such a distinction is invalid since not only are many typical colloids, *e.g.*, colloidal gold and grass fibres, crystalline, but the rates of diffusion of all particles in a medium obey the same fundamental laws, whether those particles are sub-microscopic in size like the simple molecules or clearly visible even to the naked eye, such as coarse suspensions.

The fundamental property which imparts to colloidal systems their peculiar characteristics is exhibited most clearly by the property of adsorption. Adsorption is purely a surface effect, and conditions under which adsorption may occur are brought about whenever a fresh surface is produced. Such surfaces are necessarily interfaces, *e.g.*, at the boundary of a solid exposed to a gas or liquid; even in a high vacuum we must imagine the existence of a gas phase consisting of the vapour of the substance: thus with the possible variation in interfaces produced by the mutual contact of phases such as gas, immiscible liquids and immiscible solids, a great variety of colloidal systems may be produced. Since the chemical and physical properties of a system are, as it were, in competition with the properties of the interfaces of the system, it is necessary, if these latter are to be dominant, so to prepare the system that it shall contain a large specific surface or that one phase shall be extremely subdivided; such division is readily accomplished by dispersion. When we enquire further as to the cause of the property of adsorption exhibited by interfaces we find that we must attribute to liquid and solid surfaces a certain surface energy. In the case of liquids it is a relatively simple matter both to demonstrate and measure this surface energy. That soap bubbles, small drops of liquid, or, as in Plateau's beautiful experiments, a mass of oil suspended in water, take up, when in a position of equilibrium, a perfectly spherical form indicates that some force is operative in causing both drops and bubbles to present the minimum of surface compatible with their volume. It is also clearly evident in a qualitative manner at least that a molecule in the interior of a liquid is attracted by its neighbours by the forces of cohesion equally in all directions, whilst a molecule on the surface is only attracted downwards and laterally; thus the surface energy of a liquid is closely related to the forces of molecular cohesion.

Again we find out readily by experiment that bubbles have to be blown; work is done when we expand the film of the bubble just as we must do work when we blow up a football or balloon. A simple mathematical calculation shows us that there exists an intimate relationship between the pressure of air inside the bubble and the surface energy of the material of the film; the excess pressure is directly proportional to the surface energy and inversely proportional to the radius. By this and several other methods it is possible to measure with a high degree of accuracy the surface energy of liquids; these vary in a marked manner from liquid to liquid as indicated by the following figures.

Substance.	°C.	σ in ergs. per cm^2.
H_2	—252	2
Ar	—186.1	12.7
Br_2	+20	38.0
NH_3	—29	41.8
C_6H_{14}	20	17.4
CCl_3H	20	26.3
C_6H_6	20	28.2
$C_6H_5NH_2$	20	43.8
H_2O	0	75.7
K Br	734	88.8
Li Cl	608	140
K	58	360
Hg	15	436
Ag	1060	750
Fe	1200	ca. 1000
Pt	1770	1500–2000

Applying a reasoning similar to the above to the case of small drops of liquid we find that the vapour pressure above a small drop will be greater than that above a large drop, a matter of importance. we may note in passing, in the formation of mists and fogs.

Since liquids exert a surface tension it is only reasonable to assume that solids also are endowed with this characteristic property, which is the resultant of the unbalanced forces of molecular cohesion.

Unfortunately, a solid is not readily deformed by the surface forces, the forces of crystallisation being so much stronger; thus direct methods of measuring the surface energy of solids are not available, we are forced back to indirect methods of computation. On the assumption that small crystals behave in a manner similar to small drops of a mobile liquid, an estimation of the surface tension of a solid may be computed as Pawlow has shown from the melting point, or as investigated by Ostwald and Hulett from the solubility of such small crystals. The computed values determined in this way gave a value for calcium sulphate of 1,050 ergs. per sq. cm.; more recent experiments by Dunden and Mack have reduced this value to 370 ergs. per sq. cm. It is, however, very doubtful whether the basic assumption of identity in behaviour of a small crystal and a drop of liquid is correct, thus casting doubt upon the validity of these values.

The very fact, however, that a certain amount of energy must be expended in breaking a crystal indicates at least the existence of powerful forces at solid surfaces; that these forces persist after cleavage is made clear by the fact that clean sheets of mica, of optical glass and of smooth clean metals, can frequently be joined together again by the exertion of but a slight pressure to form a solid, showing no discontinuity at the original plane of separation.

When considering the part played by this surface energy in adsorption it must not be forgotten that the free energy of the cohesive forces, and thus the surface tension, varies in magnitude with the temperature. In general on expansion of a surface the surface cools; the total surface energy being related to the free surface energy or surface tension by the relationship.

$$u = \sigma - \theta\left[\frac{\delta\sigma}{\delta\theta}\right]$$

Over a wide range in temperature the temperature coefficient of the surface tension $-\frac{\delta\sigma}{\delta\theta}$ is constant, and σ is found to decrease with the temperature. Thus we should expect that the adsorption at interfaces would decrease with elevation of the temperature, and this actually occurs.

Owing to the existence of such surface energy, substances, unless otherwise constrained, will attempt to lower the free energy associated with the exposure of the interface: this, as we have seen, can be accomplished by acquiring a spherical shape. We can likewise imagine the coalescence of small spheres to form a large one with less specific surface. The surface energy may also be lowered by adsorption; thus the addition of fatty acids to water lowers the air liquid surface tension and in consequence the fatty acids will tend to collect at the air liquid interface, but a limit will be set to the amount there collected by the opposing osmotic forces created by the difference in concentration between the bulk of the solution and the surface layer. Gibbs showed that there existed a close relationship between the excess concentration at the surface per sq. cm. (Σ) over the bulk concentration(ε) and the effect of the solute on the surface tension of the solution is usually expressed in the form

$$\Sigma = -\frac{\delta\sigma}{\delta\mu}$$

where μ is the activity or chemical potential of the substance in the solution. Substances which would cause an increase in the surface energy will conversely tend to leave the surface layer and move into the bulk of the solution.

In the same way a solid surface will adsorb gases, liquids or liquids and dissolved solutes if a diminution in the free surface energy of the system may be effected by such adsorption.

As we have already had occasion to note, the forces of adsorption are intimately connected with the forces of cohesion, and are thus chemical in their nature; we would thus expect that all substances are not adsorbed with equal facility. There is a preferential adsorption for those substances in which the reaction of adsorption, proceeds with the greatest decrease in the free energy of the system. Thus if a silica jel be exposed to a mixture of hydrogen and benzene vapour, the benzene will be more readily adsorbed than the hydrogen. Similarly carbon monoxide is more readily adsorbed by metals than hydrogen, but both gases are actually adsorbed. Thus the adsorption of hydrogen, carbon monoxide and of a 90 : 10 hydrogen carbon monoxide mixture by 1.45 c.c. of clean copper made to expose a large area by special preparation yielded the following results:

Vol. of CO adsorbed, 0.99 c.c.
Vol. of H_2 adsorbed, 0.12 c.c.
Vol. of mixture adsorbed, 0.23 c.c.
Composition of mixture, CO : H_2 16 : 1

In solutions as well we find that selective adsorption occurs not only at the air liquid interface, but also at interfaces produced on the insertion of a solid in the liquid. Thus the fatty acids, various colouring matters and many salts are preferentially adsorbed by charcoal from aqueous solutions. In all cases, however, both solvent and solute are adsorbed. This property of adsorption from solution is made use of in the many processes of purification and decolorisation. In the case of solids it is evident that we cannot test the Gibbs equation expressing the relationship between the decrease in the surface energy of the solid liquid or solid gas interface, and the concentration in the adsorbing layer. So many attempts have been made to obtain a relationship between the concentration or activity of the material undergoing selective adsorption in the liquid or the gas phase and the amount adsorbed.

The most general formula is that proposed by Freundlich in which the relationship between the amount adsorbed x and the concentration of the solute c, or the pressure of the gas is expressed by means of an equation of the type

$$x=ac^{\frac{1}{n}} \text{ or } x = ap^{\frac{1}{n}}$$

containing two constants a and n.

As typical of the values obtained the following may be cited:

(a) *Gases.*	Charcoal. Adsorbing material. $\frac{1}{n}$	Glass. Adsorbing material. $\frac{1}{n}$
CO_2	0,394	0,66
$N.H_3$	0,437	0.53
SO_2	0,324	0,28

(b) *Aqueous Solutions.*	+n
Iodine on starch	5
Methylene blue on cellulose	2
Indigo carmine on silk ..	2
Alizarine on chromic oxide..	3
Iodine in alcohol on charcoal	4
Potassium chloride on charcoal	1

Although the equation of Freundlich represents the results fairly closely it is by no means accurate, for, as we have noted, in a gas mixture or a solution all constituents are adsorbed, the more reactive being more readily adsorbed. In some cases the phenomenon of negative adsorption is noted; the strength of a solution instead of being decreased by passage through a layer of charcoal or bauxite apparently becomes stronger since relatively more solvent than solute is adsorbed by the material. Thus dilute solutions of potassium nitrate exhibit the phenomenon of negative adsorption when exposed to a charcoal surface.

Again, there is a large volume of experimental evidence that the adsorption of many substances, especially what are termed non-polar substances, at high temperatures and low concentrations does not proceed indefinitely as the pressure or concentration is raised, as would be anticipated if Freundlich's equation held true ; but that a saturation maximum is attained as if the surface could hold so much adsorbed material and no more. Langmuir has in fact shown that for such substances each atom of the adsorbent holds one atom of the adsorbate, and that the surface is saturated when it is covered with a film only one molecule deep.

The work of Hardy, Langmuir and N. K. Adam on surface tension of solutions and interfacial tensions between liquids, gives us a yet deeper insight into the mechanism of adsorption. If we bring two liquid surfaces together a certain decrease in the free energy will take place; thus if σA σB σAB be the surface energies of the two liquids and of the interface, then the decrease in free energy on bringing the surfaces together is given by the expression

$$W=\sigma A+\sigma B-\sigma AB$$

In the following table are summarised some of the values for this decrease in free energy when various liquids are brought into contact with water and mercury.

Substance.	*With Water.* *W.*	*With Mercury* *W.*
Petane	18.9	
Heptane	20.6	60.8
Octane	21.6	65.5
$C\,Cl_4$	24.0	74.8
Water	73	91.5
Ethyl iodide	—	110
Methyl iodide	—	110
Carbon disulphide	21	90
Ethyl ether	39.9	
Alcohols	47.8—51.8	
Organic Acids	46—50	
Ethyl esters	37—46	

It is evident that the decrease in free energy, when a liquid is brought into contact with the water or mercury, is most marked when the former contains a reactive group such as the hydroxyl, ether and carboxyl for water, the halide, sulphide and hydroxyl for mercury.

The action of the adsorptive forces is apparently to attack the adsorbed molecule by means of a specially reactive part of the molecule, and the molecule is orientated. Thus in the case of the fatty acids floating upon water we would expect from these considerations that they are orientated with the reactive carboxyl groups in the water and the paraffin chains emerging in a vertical plane from the water surface. If we count the number of molecules required just to saturate the surface of a known area of water, and measure also the molecular volume of the substance being adsorbed, we can evidently compute both the cross sectional area and the length of the molecule. This work, which was commenced by the late Lord Rayleigh and brought into prominence by I. Langmuir, is now being continued by Mr. Adam, and is of great interest owing to the fact that we can check the sizes of the molecules measured in this way by the data obtained by Sir William Bragg and Mr. Shearer with the X-ray goniometer. As an example some of the data obtained by Langmuir and Adam for fatty acids and alcohol on water may be given :—

Substance.	*No. of atoms in chain.*	*Cross Section Area.*	*Cross Section Side.*	*Length*	*Length per carbon atom.*
Palmitic acid	16	21	4.6	24.0	1.5
Stearic acid	18	22	4.7	25.0	1.39
Cerotic Acid	26	25	5.0	31.0	1.20
Myricyl alcohol	31	27	5.2	41.0	1.37

It will be noted that the cross sectional area of each acid is practically constant and that the increase in length for each carbon atom added to the chain is likewise so. The most accurate surface tension data indicate a mean area of 20.1 A, whilst calculation from a knowledge of the molecular volume of a methylene group 17.8 cc., and the distance between the carbon atoms in a diamond from X-ray measurements of 1.52 A°, yields a value for the cross section of 19.3 A°. In a similar manner Adam found the area of the unit cell of benzene to be 23.8 A°, whilst Shearer and Bragg obtained 23.3 A°.

The orientated film of fatty acid floating on the surface of the water can be compressed or expanded by decreasing or increasing the area of the surface on which a known amount of fatty acid is present. A typical curve obtained in this way is shown in the following diagram:

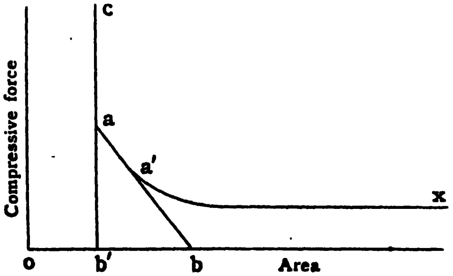

Fig. 1.

At high compressions in the region *ac* the curve is nearly parallel with the *y* axis, the molecules of fatty acid are packed as closely as possible and form the prolongation of the curve to *b'*, we obtain in *ob'* measure of the cross section of the paraffin chains which we have noted is 21 A°. From the slope of the curve *ac* it is evident that we can determine the compressibility of the film, and it is interesting to note (in confirmation of our hypothesis) that the compressibility of the fatty acid determined in this way agrees with the compressibility of a paraffin hydrocarbon. The curve *ca* on expansion shows a portion *aa'*, and the length of the line *ob* representing the area of this portion under zero compression is 25A°. Evidently there are two portions of the molecule which have different areas and different compressibilities. It is extremely probable that this second and larger portion is, as Adam has pointed out, the head of the molecule, *i.e.*, the area of the cross section of the carboxyl group is 25 A°. Adam in this way has measured the sizes of various heads of molecules; thus he finds the following values -COOH 25 A°, -NHCO the following values: -COOH 25 A°, $-NHCOH_2$ 25.5°A, and -CHBrCOOH from 26°A to 32.8°A, depending on the closeness of the packing.

We are thus dealing with a two-dimensional solid which can by suitable elevation of the temperature be turned into a two-dimensional liquid. The melting point of the acids in their two-dimensional layers is some 240°C lower than the same acids when in bulk. Under low pressures the two dimensional liquid expands the relationship between the area and the effective surface pressure, being indicated by the curve *xa'*. We are in this range dealing with a two-dimensional vapour and, as both Langmuir and Adam have shown, the ordinary Van der Waal law connecting pressure and volume, *i.e.*, $(P + \frac{a}{v^2})\ (v - b) = RT$, can be applied to this degraded two-dimensional gas.

The assumption that the Gibbs layer is only one molecule thick leads to very interesting conclusions. As we have noted from the Gibbs equation, the surface concentration should continue to alter as long as the addition of more solute affects the surface energy ; consequently if we measure the critical concentration of the solute in solution or the partial pressure of the gas above a solution at which the surface energy is no longer affected we know that the Gibbs layer is either saturated with solute in cases of positive adsorption, or contains only pure solvent in cases of negative adsorption, and with the aid of Gibbs' equation we can calculate the quantity (per sq. cm.) present. Since we assume that the film is only one molecule deep, we are thus in a position to measure the area and length of the molecules of substances which are soluble in solvents, whereas the method of Langmuir and Adam is only applicable to substances insoluble in the solvent.

The following molecular dimensions have been determined in this way:

	Area in A°.	Length.
On Mercury.		
Methyl acetate	27	—
Rubidium	12.4	4.46
Solvents with K Cl.		
Water	7	4
Ethyl alcohol	22	4.4

The information derived from a study of surface tension leads us to the conclusion that the molecules adsorbed at the surface of a liquid are orientated by attachment to the liquid at specific points, and that in general only one layer of such adsorbed molecules exists. There is little doubt that molecules are adsorbed on solid surfaces by similar forces and are similarly orientated. If the indirect measurements of the surface energy of solids are in any way reliable, their surface energies are much greater than for liquids, and it is to be anticipated that when one molecular layer of the adsorbate has become attached the new surface of adsorpate might still exert a by no means inconsiderable adsorbing power, permitting a bi-molecular film to be formed. Data on the adsorption of gases by solids indicate that, in all probability for those gases in which the intermolecular attraction is normally large as indicated by the $\frac{a}{v^2}$ term of the Van der Waals equation, multimolecular layers on the adsorbed film do in fact exist; this is the case for gases at low temperatures, high pressures, and which possess highly polar molecules.

The conception that adsorption takes place at all interfaces and that the adsorbed layer consists of molecules orientated by attachment at certain specific points in the molecule, is at the present time finding many extremely important industrial applications.

In lubrication it has long been known that a pure hydrocarbon exerts but little lubricating power, but that a hydrocarbon can be converted into a relatively good lubricant by the addition of small quantities of fatty acids or the higher alcohols. This matter is receiving exhaustive examination by Hardy, who has shown that in all probability the fatty acid or alcohol is adsorbed by means of its polar group to the surface of the metal; and the hydrocarbon tail of the adsorbed film, which, as we have seen, possesses but little adhesional power for other hydrocarbon chains, is the real surface at which slip takes place: we are in fact protecting the metal surfaces with a strongly adhering oil film. The data on the decrease in free energy at mercury surfaces wetted with various liquids will doubtless reveal many other possible addition agents, such as the organic halides suitable for conversion of a hydrocarbon into a lubricant.

In the last series of Cantor lectures which I had the honour to give to you, I dealt at some length with the problem of catalysis and we saw there that the mechanism of heterogeneous catalysis was most readily explicable on the assumption that the reacting molecules were adsorbed by the catalyst surface in juxtaposition to one another and there reacted. During the last few years this subject has been receiving a great deal of attention and we now know of many cases in which adsorption does take place, but not any catalytic action. In such cases we have every reason to believe that the adsorbed molecules are oriented in the wrong way for mutual action, for by changing the catalyst so as to effect adsorption by another point of attachment to the molecule, reaction will proceed. Many organic substances, such as alcohols and formic acid, undergo different catalytic decomposition as the catalyst is varied, and in this case also we believe that the molecules of the adsorbate may be attached to the solid by more than one point of attachment, the relative strengths of these bonds being the determining factor in the subsequent molecular decomposition. It must be admitted that exact experimental proof of this hypothesis is still lacking, but the amount of indirect evidence in favour of such a hypothesis is rapidly increasing.

In biological investigations also the conception of orientated adsorption is proving fruitful in the better understanding of many complicated surface reactions.

The enzymes are the organic catalysts, and their catalytic activity must be interpreted in the light of our knowledge that the reactants are adsorbed on the surface of the enzyme. The numerous studies that have been made on the rate of enzyme action by Armstrong, Bayliss and others, have shown that such adsorption does in fact take place, and that the reaction velocity is affected by the strength of such adsorption. Thus if the reactant is adsorbed strongly the enzyme surface will, over a great range of bulk concentration, possess a constant surface concentration, and the reaction velocity will be dependent merely on the quantity of enzyme present and independent of the concentration of the reactant. In some hydrolytic processes the products of the reaction are strongly adsorbed and the active surface of the enzyme gradually diminishes during the course of the reaction, due to such adsorption, and a species of negative autocatalysis is impressed upon the reaction velocity time curve.

Both the inorganic catalysts and the enzymes are highly susceptible to poisons. All other substances which are more strongly adsorbed than the reactants may be regarded as poisons, but some poisons are less virulent than others in that the adsorptive forces are weaker, permitting of their subsequent ready removal.

In the inorganic catalysts we have noted that in a few cases evidence is forthcoming that the adsorbate may become attached to the adsorbent by more than one point of attachment.

The organic enzymes appear to permit of such multi-point attachment. Although little is known at present as to the nature of enzymes, they appear to contain a number of reactive groups in each molecule, *e.g.* -N.H$_2$.-OH, -COOH. The enzyme particle likewise appears to be an aggregate of these complex molecules similar to the micellæ of a soap which we shall have occasion to discuss, and thus we may regard the surface of an enzyme as a regular chequer board with these active groups arranged in pattern on the surface. A reactant that can undergo reaction with the aid of the enzyme must attach itself to one or more of these reactive groups. Similar considerations can be applied to the action of germicides on micro-organism. In this case the presence of both acid and basic groups (acceptors) in the micro-organism can readily be demonstrated. In stapylococcus, for example, the basic acceptors are stronger than the acid ones, and the micro-organism is as a result more sensitive to acid germicides, With B. coli the reverse holds true. We thus see the beginning of selective action, which is the great characteristic of the more complicated organic structures met with in biology. If we imagine that the surface of the enzyme or of the bacterium contains two reactive groups or acceptors, *e.g.*, *a* —NH$_2$ and *a* —COOH group in each molecule, at a distance apart depending on the number of carbon atoms between them, then a reactant which can react with both of these groups must contain its complementary reacting groups at approximately the same spacing in its molecule. Thus the hypothesis of multipoint adsorption leads us at once to a new interpretation of the old simile of the key and the lock.

SWEDISH HYDRO-ELECTRIC POWER RESOURCES.

According to the Report on the economic commercial and industrial situation of Sweden by the Commercial Secretary to H.M. Legation at Stockholm, it is estimated that the total energy available from waterfalls in Sweden amounts to about 6,000,000 h.p., of which some 4,500,000 h.p. is owned by municipalities and private concerns. Of this amount about 1,322,000 h.p. has already been developed and work is in progress for the harnessing of a further 90,000 h.p. In terms of hydro-electric energy the total utilisable resources are put at 42,625 million kilowatt hours per annum. It is stated, on expert authority, that this estimated energy could be more than doubled if the maximum fall of the entire volume of water in the country could be utilised. A recent estimate points out that about 40 per cent. of the Swedish rural districts are supplied with electricity by means of state, municipal, and private plants. Many plans are being studied for further extensions, among which may be mentioned the regulation of the water level of Lake Vänern. These plans will shortly be presented to Parliament, and, if approved, work will be commenced as soon as possible, but it is not anticipated that it can be completed before 1930.

It is expected that work will be commenced during 1924 in connexion with the harnessing of the Norrfors waterfall in Ume river, where some 100,000 h.p. is available. A comprehensive scheme is being prepared for enlarging the well-known Trollhätta power station, and operations are now in train for including the lower waterfall in the Göta river at Lilla Edet in the Trollhätta power net, which will yield an additional 33,000 h.p. The electrification of the main line railway from Stockholm to Gothenburg, work on which is now in full swing, will entail a large scheme for the reinforcement of existing power cables, the erection of new transformer stations, etc. The surplus revenue which the Royal Swedish Waterfall Board was able to hand over to the Treasury for 1923 working year amounted to Kr. 8,300,000, and the estimate for 1924 is put at Kr. 10,000,000.

Journal of the Royal Society of Arts

No. 3,753. VOL. LXXII.

FRIDAY, OCTOBER 24, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. 2.

NOTICES.

OPENING OF THE 171st SESSION.

The Opening Meeting of the 171st Session will be held on Wednesday, November 5th, when an address will be delivered by Senatore Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., Chairman of the Council. The chair will be taken at 8 p.m.

COUNCIL.

A meeting of the Council was held on Monday, October 13th, Present: –

Mr. Alan A. Campbell Swinton, F.R.S., in the Chair; Sir Thomas J. Bennett, C.I.E.; Mr. A. Chaston Chapman, F.R.S.; Sir William Henry Davison, K.B.E., D.L., M.P.; Sir Archibald Denny, Bt., LL.D.; Mr. P. M. Evans, M.A., LL.D.; Sir Robert Hadfield, Bt., D.Sc., D.Met., F.R.S.; Rear-Admiral James de Courcy Hamilton, M.V.O.; Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.; Sir Herbert Jackson, K.B.E., F.R.S.; Major Sir Humphrey Leggett, D.S.O., R.E.; Sir Philip Magnus, Bt.; Colonel Sir A. Henry McMahon, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I.; Mr. Carmichael Thomas; Sir Frank Warner, K.B.E., and Sir Alfred Yarrow, Bt., M.Inst.C.E., F.R.S., with Mr. G. K. Menzies, M.A. (Secretary of the Society) and Mr. S. Digby, C.I.E. (Secretary of the Indian and Dominions and Colonies Sections).

The arrangements for the forthcoming session were considered and approved.

It was reported that a selection of textile designs from the Society's Exhibition at the Victoria and Albert Museum had been sent for further exhibition at Manchester, and that the glass designs had been forwarded to Stourbridge and Wordsley for exhibition at those places.

The sum of £200 has been voted by the Council to be used as prizes for encouraging candidates to take group certificates at the Society's examinations.

The Clothworkers' Company again promised £40 towards providing medals at the Society's Examinations.

A beautiful miniature of William Shipley, the founder of the Society, by William Hincks, was presented to the Society by Mr. Herbert Monckton, of Maidstone.

Subjects for the Peter Le Neve Foster and Fothergill prizes were considered.

Other formal business was transacted.

DOMINIONS AND COLONIES SECTION COMMITTEE.

Senatore Guglielmo Marconi, G.C.V.O., LL.D., D.Sc. (Chairman of the Council).
Lord Blyth (Chairman of the Committee).
Marquess of Aberdeen and Temair, K.T., G.C.M.G., G.C.V.O.
Colonel Hon. Sir James Allen, K.C.B., M.A. (High Commissioner for New Zealand).
Lord Askwith, K.C.B., K.C., D.C.L.
Sir Charles H. Bedford, LL.D., D.Sc.
Byron Brenan, C.M.G.
Sir William H. Clark, K.C.S.I., C.M.G.
Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.
Hon. Sir John A. Cockburn, K.C.M.G.
Hon. Sir Timothy Augustine Coghlan, K.C.M.G., I.S.O. (Agent-General for New South Wales).
Hon. H. P. Colebatch (Agent-General for Western Australia).
Hon. Sir James Daniel Connolly.
Sir Joseph Cook, P.C., G.C.M.G. (High Commissioner for Australia).
Sir Edward Davson.
Edward Dent, M.A.
Hon. G. Fairbairn (Agent-General for Victoria).
W. L. Griffith.
Rear-Admiral James de Courcy Hamilton, M.V.O.
P. J. Hannon.
Sir Thomas H. Holland, K.C.S.I., K.C.I.E., D.Sc., F.R.S.
Hon. J. Huxham (Agent-General for Queensland).
Viscount Inchcape, G.C.S.I., G.C.M.G., K.C.I.E.
Hon. Peter C. Larkin (High Commissioner for Canada).
Major Sir Humphrey Leggett, D.S.O., R.E.
Hon. Sir Edward Lucas (Agent-General for South Australia).
Rt. Hon. Sir Frederick Lugard, G.C.M.G., C.B., D.S.O., D.C.L.

Sir Charles Campbell McLeod.
Sir Charles Metcalfe, Bt.
Sir Robert W. Perks, Bt.
Lieut.-Colonel Sir Thomas Bilbe Robinson, G.B.E., K.C.M.G.
M. L. Shepherd, I.S.O.
Lieut.-Colonel R. E. Snowden (Agent-General for Tasmania).
Major H. Blake Taylor, C.B.E.
Carmichael Thomas.
F. C. Wade, K.C. (Agent-General for British Columbia).
Hon. Sir Edgar Walton, K.C.M.G. (High Commissioner for South Africa).

CANTOR LECTURES.

COLLOID CHEMISTRY.

By Eric K. Rideal, M.B.E., Ph.D., D.Sc., F.I.C.

Lecture II.—*Delivered January 28th*, 1924.

In this lecture I should like to devote the time to the consideration of the suspension colloids in which a solid phase is finely dispersed in either a liquid or gaseous dispersion medium forming sols and smokes respectively, and we shall have occasion to note how different are the properties of such a disperse system from the solid material one, due, as we have already noted in our last lecture, to the operation of surface forces. A solid disperse phase may evidently be prepared in two ways either by growth from molecules in solution or by dispersion of a bulky solid. In industrial practice both these methods are adopted for preparing colloidal sols and we must consider the various factors governing the formation of disperse systems by these means.

Methods of condensation.

If a solution of salt be undercooled the solution will become relatively supersaturated owing to the fact that salt is more soluble in hot than in cold water. The formation and growth of crystals in such a supersaturated solution are in reality two independent processes. For a crystal to start growing it is necessary as we have already noted for a nucleus to be present, the solubility of which is less than concentration of the solution; once a nucleus is formed it proceeds to grow by the diffusion of the molecules of the various minute crystal faces. Gibbs has pointed out that the various crystal faces may possess different surface energies and thus those faces which possess the smallest interfacial surface energy will be most stable. If the conditions are favourable to very rapid growth, however, not only will faces appear which possess higher surface energies but the molecules may actually become attached to the surface in positions which are not in the regular crystalline space lattice and we thus build up a partly regular and partly irregular molecular structure. Such a particle will possess a high superficial surface energy. On warming the energy will gradually decrease since the thermal oscillations of the attached molecules when sufficiently vigorous will permit of their entering their proper position in the crystalline space lattice; such an operation, known as sintering, is frequently made use of in the baking of materials such as are employed for brick and pottery manufacture and in the production of solid metals from powders, as in the case of tungsten.

A sol consists of a highly dispersed solid; thus in order to prevent the growth of a relatively few large crystals it is evidently necessary to ensure the simultaneous formation of a large number of nuclei which must grow extremely rapidly. These principles have been developed in detail by von Weimarn, who has shown that we may obtain materials in either the crystalline or colloidal state by alteration of what is termed the dispersion coefficient; the dispersion coefficient being defined by the equation

$$\delta = \frac{C}{S}$$

where C is the degree of supersaturation or equivalent concentration in the solution and S the solubility. A high dispersion coefficient ensures the formation of a small grain or potential colloid. I might quote the result of one of von Weimarn's numerous experiments on the interaction of barium sulphocyanide and manganous sulphate in aqueous solution resulting in the formation of barium sulphate usually obtained in the crystalline condition.

Dispersion Coefficient.	Nature of product.
0—3	Several years to crystallise.
3—48	A fine crystalline deposit obtained after a period of a month to a week.
48—88,000	First granular, then curdy, then gelatinous.
88,000—200,000	A viscous jelly.

This method of preparation is generally employed for the preparation of metal sols since, owing to the almost vanishingly small value of $\frac{C}{S}$, the solubility of the metal in the dispersion medium, large values of δ favourable to the formation of a system of high dispersity are rapidly obtained.

Methods of dispersion.

Mechanical dispersion may be accomplished by processes of heating, hammering and trituration or in the electrical arc. All these methods are employed for the preparation of sols, the electric arc process being most general in the laboratory, whilst the various colloid mills are used in industrial work.

Such methods of mechanical dispersion, however, do not in themselves, as would be expected, lead to the formation of stable sols, a point which we shall see is of great importance not only in the technical but the theoretical development of colloidal chemistry. The observations of many investigators, commencing with Leeuwenhoek in the seventeenth century, of Robert Brown, Wiener, Jevons and Gouy, in the nineteenth, and the more recent investigations by Zsigmondy, Perrin and Einstein, have shown that the small particles of the solid are in continuous agitation moving across the field of a powerful microscope or as a point of light in the ultramicroscope in a curious tremulous zigzag fashion.

Such motion, the Brownian agitation, has been shown to be due to molecular bombardment; we are in fact observing the movements of particularly large molecules under the impacts constituting the molecular thermal agitation. Although the assemblage of molecules forming the colloidal particle may have an apparent molecular weight of over 50,000 tons, yet it moves in the dispersion medium exactly the same in type and extent of its motion as can be predicted for a gigantic molecule. Its movements are naturally not so lively as the small molecules, since the sudden impact of a molecule bombarding its side would have but little effect on its motion, but every now and again a sufficient number of molecules of the circumambient dispersion medium hit one side to give the particle a movement in that particular direction, thus giving rise to the characteristic zigzag motion previously alluded to. In this connexion it is interesting to note that Perrin has shown that the probability of a sufficient number of air molecules hitting one side of a brick weighing a kilogram, to give the brick a perceptible movement, occurs once in $10^{10^{10}}$ years.

The sol particles behave like large molecules in respect to the movements of thermal agitation and rotation; we should thus expect that chance of collisions between particles would occur with some frequency and that under the influence of the surface forces coalescence would occur and the sol would rapidly flocculate or precipitate. This, however, is, in general, not the case; sols are frequently extremely stable and may be preserved for a number of years. Faraday's original colloidal gold may yet be observed in the Laboratory at the Royal Institution. There are certain factors which render the dispersion stable; the two important factors making for stability of sols are the electric charge and the interfacial surface tension. These two factors are to some extent related since the charge on a surface affects its surface tension, but the exact relationship between these two factors, if any such exists, has not yet been developed in detail.

Colloidal sols to be stable must possess an electric charge; it is found that certain sols such as the colloidal metals, colloidal sulphides, gums and oils possess in general a negative charge, whilst hydroxides and oxides of the metals, many dyes such as Bismarck brown, methylene blue are positively charged.

The production of an electric charge on a colloidal particle may result in two different ways; if an electrolyte be present in the dispersion medium it will be adsorbed at the interface. In general the adsorptive power of the interface is not identical for anion and cation of the electrolyte; there will consequently be a preferential adsorption of one ion, *e.g.*, the anion for colloidal sulphides and oils, the cation for methylene blue.

Evidently the preferential adsorption of an ion produces an interfacial electrification with the result that the ions of opposite sign are held to the outside of the electrified surface producing an electrical double layer, likewise we must note that the ions of opposite sign at the outside of the double layer are attempting to pull off the preferentially adsorbed ion; thus the preferentially adsorbed ion is not adsorbed to its equilibrium concentration, whilst the less adsorbable ion is adsorbed in excess of the concentration at which equilibrium would be attained in the absence of such electrical effects. Again many colloidal sols acquire an electric charge by surface ionisation; thus in the formation of colloidal ferric hydroxide from ferric chloride by a process of dialysis we have every reason to believe that the particle of the sol is constituted of ferric hydroxide containing a small quantity of ferric chloride.

$$\left\{\mathrm{Fe(OH)_3}\right\}_n \quad \mathrm{FeCl_3}$$

which on dispersion in water undergoes partial ionisation to

$$\left\{\mathrm{Fe(OH)_3}\right\}_n \mathrm{Fe}\overset{+}{\mathrm{Cl}}_2 + \mathrm{Cl}^{|}$$

the particle thus acquiring a positive charge.

The electric charge on a particle causes the particle to acquire a potential with respect to its environment. If the particle be spherical at radius r and had a charge e its potential will be $\frac{e}{kr}$ where k is the specific inductive capacity of the material. The stability of a colloid is governed by this potential—the electro-kinetic potential. For water a sol is stable if the potential exceeds some 35 millivolts, and it may rise as high as 70 millivolts. To prepare a sol from an amorphous precipitate it is evident that we must give the particles a charge; this can be done by adding to the solution containing the precipitate a small quantity of an electrolyte of which one ion is readily adsorbed; this is termed ionic peptisation. Colloidal silver iodide may be prepared from precipitated silver iodide by the addition of small quantities of either silver nitrate or sodium iodide, as the solid readily adsorbs both silver and iodine ions; we can in this way form either a positive or negative colloidal solution of silver iodide.

To stabilise small particles we may, as we have seen, lower the interfacial surface tension between the particle and the dispersion medium; this can be accomplished by adding to the solution some material which is more strongly adsorbed by the surface than the dispersion medium. Zsigmondy noted that gelatine, soaps, gums, hæmoglobin, lysalbic and protalbic acids functioned as protecting agents, *i.e.*, increased the stability of the particle by such preferential adsorption. More recent experiments, however, have indicated that the problem of protection is somewhat more complex. Thus colloidal gold is usually negatively charged; if we add to the gold solution some gelatine, protection will ensue, but gelatine can act both as an acid and a base, being in fact an amphoteric electrolyte. Thus on the addition of gelatine on the basic side the gelatine will be negatively charged and the protected colloid will be negative. If, on the other hand, we add gelatine on the acid side of what is termed the isoelectric point, the gelatine will be positively charged; this will adhere to the gold particles, discharge them and precipitate the gold, but on the addition of larger quantities the gold will be repeptised and we shall obtain a stable positively charged protected gold sol.

We have noted that bringing oppositely charged colloids together results first in adsorption, resulting in a lowering of the electro-kinetic potential and consequent precipitation. On further addition the precipitated colloid may adsorb more of the colloid and become stabilised again but of opposite sign.

Precipitation may likewise be produced by the addition of electrolyte containing easily adsorbable ions of opposite sign. Since precipitation is produced by neutralisation of the electric charge very much smaller quantities of trivalent ions, *e.g.*, aluminium, than of divalent or monavalent ions will be required. The adsorption of trivalent ions is likewise more pronounced than those of lesser valency, consequently, but minute amounts of trivalent ions are required to effect precipitation some thirty two times the concentration of divalent ions and about one thousand times the concentration of monovalent ions being required. The adsorptive power of a colloid for an ion depends, as we have noted, not only on the electrical charges of the two but also on the surface forces which are chemical in character, and thus we find that the monovalent organic ions of the dyestuffs or aniline and its homologues are much more effective than the simpler inorganic ions. The following data indicate that although the same electrical equivalent amounts are adsorbed when precipitation results, yet the concentration of electrolytes in the bulk solution may be very different.

Precipitation of colloidal Al $(OH)_3$

Anion.	Bulk concentration millemols per litre.	Adsorbed quantity in mille-equivalents.
Salicylate	8	0·30
Picrate	4	0·18
Osculate	0·36	0·36
Ferrycyanide	0·10	0·27
Ferrocyanide	0·08	0·29

In general both ions are adsorbed and we should expect that the concentration of a cation required to precipitate a negatively charged colloid would vary with the nature of the anion; a feebly absorbed anion will permit of a relatively dilute electrolyte affecting coagulation. The following represent what are termed the liminal coagulating concentrations of salts possessing a common precipitatory ion for a positive and negative colloid :

Colloid.	Sign.	Liminal concentrations in millequivalents per litre.			
Pt	—	$\overset{+}{Na}Cl$	2·5	$\overset{+}{Na}OH$	130
$Fe(OH)_3$	+	$H\,\bar{Cl}$	4·00	$Ba\bar{Cl}_2$	9·64

Evidently the OH is more strongly adsorbed than the $\bar{Cl}$ by platinum, necessitating a higher concentration of the precipitatory $\overset{+}{Na}$ when present as caustic soda, whilst in the case of Fe $(OH)_3$ the Ba is more strongly adsorbed than the $\dot{H}$ by electropositive ferric hydroxide.

The stabilisation of colloids by the addition of protective colloids has received extended application; thus we find colloidal platinum employed for catalytic hydrogenation is always protected by means of gum arabic or lysalbic acid, whilst the colloidal metals and other sols employed for therapeutic purposes must be protected from precipitation of the salts present in the blood. Evidently the factors to be considered in the preparation of such substances are enhancement of stability against precipitation with suitable adjustment of their toxic action. Such action appears to be dependent, at any rate in some cases, on disintegration of the particle and subsequent reaction of the agent in a molecular or ionic form; in other cases on the adsorption of the colloid by surfaces where they can promote catalytic changes, a case of bringing the catalyst to the reactant. Over protection will evidently exert a depressing effect on the activity of such colloidal reagents, whilst the preparation of sols of insufficient dispersity is likewise to be avoided from similar considerations.

The existence of an electrokinetic potential between a particle and the dispersion medium gives rise to the phenomenon of electric cataphoresis and electric endosmose. If a couple of electrodes be placed in a colloidal solution and a difference of potential be applied, the particles, if positively charged will wander to the cathode and the mobility of the particles can readily be calculated with the aid of Stokes' law. On discharge of the particle by the addition of electrolytes the velocity which is governed by the magnitude of the charge will fall until at the isoelectric point no motion will be observed. Similarly, if the dispersion medium be brought in contact with a fixed porous diaphragm the presence of an electrokinetic potential can be demonstrated by the application of an applied electromotive force causing the liquid to move through the diaphragm. The following data obtained by Perrin indicate how the rates of electric endosmose may be caused to vary by altering the electrokinetic potentials by the addition of electrolytes :

Diaphragm material.	Electrolyte.	Diaphragm Charge.	Relative rate of endosmose.
Tungstic acid	water	+	0·26
	0·045 N H Cl	+	0·11
	0·2 N H Cl	+	0·03
	0·8 N H Cl	0	0
Gelatine	$\frac{N}{50}$ H Cl	+	2·2
	$\frac{N}{100}$ NaOH	—	3·5

Practical application of electric endosmose is made use of in the drying or dewatering of many colloidal materials such as peats and clays, and to the removal of sugar from beet, whilst we find application of electric cataphoresis to accelerate the penetration of colloidal tannic acid into hide materials and of various colloidal drugs into living tissues.

A third example of the technical application of protective measures is to be found in the recent development of colloidal fuels. Colloidal fuels consist essentially of a stable suspension of coal in a hydrocarbon oil. Although the oil solid interfacial tension may be relatively high, yet, owing to the high viscosity of the oil dispersion medium, the suspension may appear relatively stable. When, however, storage is contemplated it is necessary to add a fixateur, which is in fact a protective colloid. Tannin is said to prove efficacious, but many soft coals will undergo dispersion to a stable sol when heated to a high temperature in oil under pressure, there being evidently in the asphaltic constituent of the coal some effective peptising agent. Such suspensions may be rendered stable in this way for periods varying from a few days to several months.

Protective agents may also be regarded from a different point of view. It is evident that they are preferentially adsorbed and it is on this property, the preferential wetting of solids, that the practice of ore flotation is based. The operation of ore concentration as carried out in practice is relatively simple; thus galena can be separated from quartz by the addition of a little sulphuric acid and a drop of eucalpytus oil. On blowing air through the solution the galena is brought to the surface by the levitating action of the air bubbles which attach themselves only to this material. When the ore requires concentration for two substances such as galena and blende the problem becomes much more complicated since a selective attachment of the air bubbles to the two minerals must be obtained.

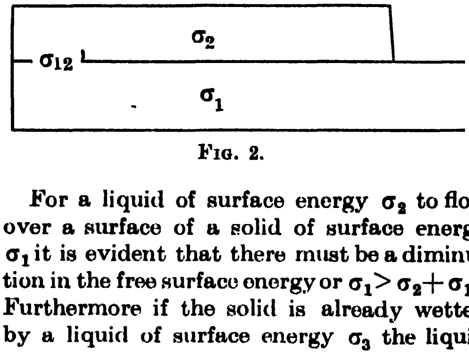

FIG. 2.

For a liquid of surface energy σ_2 to flow over a surface of a solid of surface energy σ_1 it is evident that there must be a diminution in the free surface energy or $\sigma_1 > \sigma_2 + \sigma_{12}$. Furthermore if the solid is already wetted by a liquid of surface energy σ_3 the liquid will displace the former if $\sigma_{13} > \sigma_{12} + \sigma_{23}$. As an example it may be mentioned that the surface energy of sulphur is about 26 ergs. per sq. cm., even if the energy of the sulphur liquid interface were zero it is evident that it can only be wet by liquids in which the surface energy is below 26, for

$$\sigma\begin{matrix}\text{sulphur}\\ \text{air}\end{matrix} \quad \text{must be} \quad > \sigma\begin{matrix}\text{liquid}\\ \text{air}\end{matrix}$$

Water will not wet sulphur, but if its surface energy is reduced by the addition of sodium oleate to below 26, wetting will occur.

Thus by coating the ore particles with a liquid which prevents them being wetted by the water or which will displace water from the surface small gas bubbles can adhere to them and float them to the surface. At the same time the quartz must not be so coated; hence if σ_q and σ_g be the surface energies of the quartz and galena respectively, σ_e that of the flotation liquid, and σ_w that of water, we find that

$$\sigma_{gw} > \sigma_{gl} + \sigma_{ew}$$

but

$$\sigma_{qw} < \sigma_{ql} + \sigma_{ew}$$

Many examples of such preferential wetting of solid particles have been examined by Reinders and Hofmann; thus silver iodide in water if shaken up with amyl alcohol will be preferentially wetted by the alcohol and entirely leave the water. The displacement of air from the surface of leaves by a liquid is an important consideration in the preparation of insecticides and fungicides for plants. For an insecticide to wet a leaf it is evident that the following conditions must hold:

$$\sigma \text{ leaf air} > \sigma \text{ liquid air} + \sigma \text{ liquid leaf}$$

A low liquid air surface tension is evidently a desirable factor.

Solids may be dispersed in gaseous media as well as liquid producing smokes; these are very similar in their properties to the colloidal sols. Owing to the low viscosity of the medium the Brownian agitation is most marked, promoting rapid diffusion. The particles may, in fact, be so small as to be sensibly affected by the pressure of light, as demonstrated by Ehrenhaft by the photopheresis of dusts in the light of a powerful arc lamp. In the hot stars and the tails of comets a balance between the effects of gravitational attraction and the radiation pressure appears to be the important factor in determining their stability. Again the smokes are electrically charged and can be caused to exhibit electric cataphoresis under the influence of a potential gradient which forms the basis of the Lodge and Cottrell methods of removing industrially valuable products such as potassium salts from the gases of cement kilns, the treatment of metallurgical smokes from smelting works, the cleansing of blast furnace gas, the manufacture of lamp black, and the phosphoric acid, among many other industrial operations.

We have, in our previous lecture, noted that solid surfaces adsorb gases when the solid is dispersed in a fine state of subdivision; the adsorption increases with the increase in specific surface, and we must imagine powders as being surrounded with an adsorbed gas film; fine powders can frequently be poured like liquids and certain fumes like P_2O_5 are most difficult to wet; coalescence between the particles or wetting being prevented by the air cushion. Not all gases are adsorbed with great facility and the sensitiveness of the coherers employed in wireless may be altered very appreciably by an alteration in the nature of the gas film adsorbed and insulating the contacts from each other. The effect of bellows in causing a fire to burn with greater readiness may be due to the mechanical removal of adsorbed carbon dioxide as to the supply of fresh oxygen.

The increase in specific surface of a finely powdered solid or the conversion into a mist of a liquid fuel are obvious applications of the effect of increasing the specific surface on increasing the rate of a surface reaction. Dusts in air made from inflammable materials adsorb oxygen on their surface and may give rise to serious explosions such as witnessed with coal dust where a flame velocity of 2,000 ft. per second may be attained. The ignition of such dusts may be prevented by displacing the adsorbed oxygen film by water or carbon dioxide, but these affect the health of the underground workers, and more attention is paid to preventing the propagation of the explosive wave by the addition of shale or stone dust.

In conclusion I would like to comment on one of the most striking peculiarities of colloidal systems, namely, the curious and unusual colours which they present to the eye.

One of the most characteristic of structural colours is to be observed in the case of thin films, where, as shown by Newton, the interference of light of a particular wave-length reflected from the top and bottom surface of a thin film causes the appearance of the complementary colour. Many examples of such will occur to us in the soap bubble, oil films, tempered metals, agates and pearls.

The effect of scattering of light can be noted in the case of snow or triturated coloured salts; with increase in scattering power of the surface the lighter does the solid appear, a matter of importance in the paint industry. Very small particles, scatter, as shown by Rayleigh, blue light more than red light, thus the light transmitted through a layer of finely dispersed material will appear somewhat reddish, whilst the reflected light will appear somewhat bluish. A number of cases caused by such means have been collected and examined by Bancroft; thus we find the blueness of blue eyes, of skim milk, of tobacco smoke, of the sky, and of the deep blue sea due to the scattering caused by small solid particles in a liquid or gaseous dispersion medium, whilst the blue of the kingfisher or the blue jay's feathers is caused by the scattering at the surfaces of minute air bubbles in the horny matter of the feathers. Hair goes white for a similar reason, but as far as I know no case of even acute worry has been able to reduce the bubble size in hair to cause it to turn blue.

The bright red sunsets observed during periods of volcanic activity must again be attributed to the transmission of white light denuded of the blue by scattering at the surface of dust particles.

The colours exhibited by colloidal metals are, however, the result of somewhat more complicated optical effects than mere scattering. In the case of gold the transmission of white light through a fine gold sol leads to a transmission of red light, whilst as the particles get larger the colour of the transmitted light becomes first violet and then blue, thus the small particles reflect green and blue light and the larger yellow and brown. Thin gold sheet transmits green light, thus we are dealing with resonance of light after absorption and re-emission of the metal. The work of Garnett, Gans, Neil and others has indicated that the problem becomes even more complicated when the shapes of the aggregates as affecting the scattering and the optical resonance are taken into consideration. The problem, however, is one of very marked industrial importance since the preparation of substances like enamels which consist of highly disperse sols of stannic or titanium oxides, of paints, of coloured glasses and the tints of various shades of dyes depend in a large measure on the optical effects produced by disperse systems.

NOTES ON BOOKS.

THE ECONOMIC DEVELOPMENT OF THE BRITISH OVERSEAS EMPIRE. By L. C. A. Knowles, M.A., LL.M., Litt.D., Professor of Economic History in the University of London. London: George Routledge & Sons, Ltd. 10*s.* 6*d.* net.

"To know something about the Overseas Empire at the present day is to get some idea of the whole evolution of civilisation." In this aphorism Mrs. Knowles indicates briefly the nature of the stupendous task which she has undertaken. The British Empire ranges from the Arctic to the Antartic zone; its peoples are in every stage of development; it contains almost every stage of industrial development and almost every agricultural and labour problem. "Every product, every clime, every religion, every stage, every possibility, and consequently every experiment and every problem, are encountered in the study of the economic development of the British Empire."

To attempt to boil down this multifarious and, indeed, infinite subject into a book of any reasonable size might well have appalled the boldest, but the work may be said to be the child of necessity. Mrs. Knowles was appointed to lecture at the London School of Economics on the Economic Development of the British Empire, a compulsory subject for the degree of Bachelor of Commerce, and she found that there were no text-books suitable for her students. In the smallest list that could be produced, there were references to no less than seventy books, reports and articles, and this by no means covered the ground. With a courage for which we cannot express too warmly our admiration, she set to work herself, and has produced this intensely informative and eminently readable volume.

The author found that her chief difficulty lay in the scattered and patchy nature of the material available. As a matter of fact, the economic history of most regions is not yet written. Even if it were, the mind that could grasp it in all its ramifications can hardly be expected to exist. As Mrs. Knowles writes: "In a book which ranges from slavery to Factory Acts, from cold storage to ticks and mosquitoes, from peasant culture to plantation products, from bush paths to railways, there are bound to be many gaps." But it is surprising that the gaps are so few, and that the author has such a firm grasp of so many completely different aspects of her subject.

The present volume is divided into two parts, "The Empire as a Whole," and "The British Tropics"; it will be followed by a second volume, dealing with the economic histories of Canada, Australia, New Zealand, the Union of South Africa, and Rhodesia. When the whole is complete it will provide a most admirable synoptic account of the British Empire.

The London School of Economics has now published seventy-six monographs by writers connected with the School. Many of these are very useful contributions to political science, but none of them can compare for general interest and value with this remarkable work by Mrs. Knowles.

THE ROYAL DOULTON POTTERIES. A brief summary of their rise and expansion during six reigns.

In 1815 the foundation stone was laid of what was to become a great and flourishing firm. Two young men, John Watts and John Doulton, started a small pottery in Vauxhall Walk, Lambeth, a district which has long been known as a centre of this industry. A photograph in the volume under notice shows a collection of clay tobacco pipes of the Stuart period, specimens of which are frequently excavated on the company's property.

Originally the staple output of the firm consisted of "stoneware," but about 1830 some red-glazed ware and garden pots were made, while later on a kiln was erected specially for large terra-cotta work. The entry into the firm of Mr. (afterwards Sir) Henry Doulton marked the beginning of great developments. He was the first to introduce steam for driving the wheels, in this ante-dating by ten years the use of steam for this purpose in any other pottery; and he was also the first to realise the significance to the industry of Mr. Edwin Chadwick's suggestion that glazed pipes should be used for sewers. In 1846 he erected a special factory for the production of pipes and other articles of stoneware for house and town drainage. The superiority of these salt-glazed stoneware pipes over the old and filthy brick drains was speedily recognised, and in addition to the Lambeth works, factories were erected at St. Helens, Rowley and Smethwick.

Another development due to Sir Henry Doulton was the production of what came to be known as "Doulton Ware." Much of this was very beautiful and ranged from the largest *tours de force* in exhibition pieces to the daintiest specimens of fine china. In 1885 the Royal Society of Arts conferred on Sir Henry Doulton their Albert Medal "in recognition of the impulse given by him to the production of artistic pottery in this country."

This book, with its fine photographs and coloured plates, gives an excellent idea of the size and ramifications of the great firm which, founded over a century ago, is to-day running more strongly than ever.

THE ESSENTIALS OF PRINTING. By Frank S. Henry. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd. 6*s*. 6*d*. net.

This is a text-book for beginners, and is a shorter and less elaborate work than the author's "Printing for School and Shop." Written in very simple language, it explains to the novice the operations necessary to the production of a piece of printed matter. The book appears to be admirably adapted to its purpose. Mr. Henry was formerly instructor in printing at Philadelphia Trade School; he, therefore, is familiar with the wants of students of printing, and he has the technical knowledge to supply these wants. A useful feature of the book is that a questionnaire is appended to each chapter. By means of these the reader can test his grasp of what he has read, and by the time he has finished the volume he should have a good understanding of everything connected with printing processes, from the various kinds of type to machines for cutting paper.

COLLECTIVE INDEX OF THE JOURNAL OF THE INSTITUTE OF BREWING, 1911-23. Compiled by W. H. Bird, Secretary of the Institute of Brewing. London: Harrison & Sons, Ltd.

This is an admirable index of the *Journal* of the Institute of Brewing for the years 1911-23. It is divided into four parts: (1) Authors; (ii) Subjects; (iii) General matter; and (iv) Lists of Journals from which communications have been abstracted. The work has been carried out with great care; reference is made as easy as possible; and the index should be indispensable to anyone interested in the brewing industry.

THE BRAZIL-NUT OR CASTANHA INDUSTRY OF BRAZIL.

The castanha, or Brazil-nut, is assuming an important position in the export trade of Brazil. At the present time it stands next to rubber as a source of wealth in the State of Amazonas, where more than one-half the nuts exported are produced. The following particulars regarding the Brazil-nut industry, obtained by a representative of the United States Department of Commerce, who ascended the Amazon River and some of its tributaries in making a study of rubber production, are taken from a special Bulletin published by the U.S. Bureau of Foreign and Domestic Commerce:

The Brazil-nut industry, which was of little importance until a few years ago, has recently developed to such an extent as to eclipse in importance all of the other industries of the Amazon Valley, with the single exception of the rubber industry. During the last few years the latter industry has also felt the inroads being made upon it by the prospering Brazil-nut industry. Especially during the past five years, owing to the unprecedented high prices ruling for castanha (as the Brazil-nut is locally known), the interest in the gathering and marketing of this forest resource of Amazonia has attracted much attention on the part of those ordinarily interested only in rubber.

The rise in importance of the castanha industry may be attributed primarily to the very low price prevailing for rubber, making the production of that product practically unremunerative in Brazil, in combination with the above-mentioned high prices for castanha. Another element, and a most extraordinary one, in the increase in production of castanha is a result of the unusually high rises of the rivers which have occurred during recent years. This great increase in the amount of water in the rivers during the rainy season has made possible canoe navigation for greater distances from the main rivers than was previously the case, thus giving access to larger areas of castanha forest. Aside from natural conditions influencing the yield of the trees, the quantity of castanha produced depends on facilities of transportation, for the greater the distance that the forest can be penetrated the greater will be the number of trees the fruit of which can be marketed.

DESCRIPTION OF THE TREE.

The Brazil-nut tree, commonly so called because it is found almost exclusively in Brazil, where it is indigenous, is known to science as *Bertholletia excelsa*. The name given to it in Brazil, however, is "castanha do Para" (Para chestnut) owing to the fact that all Brazilian Amazon country where the nut is encountered was known as Para until 1850, when the State of Amazonas, whose castanha production is now slightly in excess of that of Para, came into existence. Similarly, the name "castanha de Maranhao" was applied before the formation of the State of Para, when all this region was included in the State of Maranhao, but this name is now obsolete.

The tree is one of the largest found in the South American jungles, often attaining a height of more than 150 feet and a diameter of 6 feet at the base of the trunk. In the Rio Trombetas, one of the most important castanha regions, a tree was observed which measured 10 feet in diameter. The tree is unique in appearance among the others surrounding it, being distinguishable by its long straight trunk with the branches limited to its upper section. It is by nature a tree of the terra firma, where it is generally encountered in large groves. A few trees are encountered near the streams, but these are always situated on high areas well above flood water. In order to find trees in sufficient numbers to work it is often necessary to penetrate the forests 20 to 30 kilometres from the main streams. The bark of the tree is of a dark colour, and the leaves are large, deeply ribbed, and dark green in colour. The flower or blossom appears as a small white cluster, the period in which the trees flower being October to March, and the time required for the fruit to develop from the blossom stage is about 14 months. Therefore, the fruit of a tree flowering in October will fall in December of the following year.

In the Acre Territory and Rio Negro region there is a slight variation in the flowering time as compared with the other regions, owing to climatic differences, and consequently the gathering time in these two areas does not coincide with that of the other castanha producing regions. The "castanheiras" (castanha trees) of the two areas named flower from one to two months earlier than the trees of the other regions. The tree flowers first when it is in its fifth year, but does not begin to give fruit until the eighth year. At 12 years of age the tree usually begins producing to the full amount of which it is capable.

Castanha is found in greater abundance than any other fruit in Amazonia, and because of this abundance of a natural and fully developed source of wealth the castanha has combined with rubber, cacao, and the other products indigenous to this region to make the Amazon Valley dependent upon them for its economic existence even up to the present. The fruit of the castanha tree is similar in shape and size to the coconut and varies from 3 to 6 inches in diameter. It weighs from 2 to 3 pounds. The cask or outer shell, called "ouriço," is exceedingly hard and about half an inch in thickness. Inside this shell are found from 12 to 22 nuts, depending on the size of the ouriço, all fitted tightly together in juxtaposition. It is these inner nuts, containing the rich oleaginous fruit, with which the consumer outside of Brazil is acquainted. A castanheira is capable of giving from 500 to 1,000 pounds of nuts, not including the weight of the large outer shell.

History of Industry.

The first record of exports of castanha dates from 1836. The trade was of little consequence at that time, as the chief interest was in cacao, rice, cotton, hides, and coffee. It is probable, however, that a small amount of trade in castanha existed long before this, for references are encountered regarding trade between the Dutch and the aborigines of the Amazon country, even before the entrance there of the Portuguese, in various native products, among which are mentioned oil-bearing and edible forest fruits. By 1850 castanha had risen to third place among the exports of Amazonia. During this period rubber had become the most valuable export, being slightly in excess of the value of the cacao exports, while the value of rice, cotton, and coffee had dwindled to very inconsiderable quantities. Hides were fourth in importance at that time. In 1900 rubber exports were many times the value of the exports of cacao. Castanha exports, despite a considerable increase in value, were still third. During the early years of the twentieth century, owing to the greater remuneration offered, the chief interest of the people was in rubber, to the great disadvantage of other industries. Since 1914 castanha has been the second crop of Amazonia, the increase in the price of the nut, together with the fall in the price of rubber, causing a rapid development in the industry, and giving it an especial importance.

Distribution.

The castanha tree is native to the Amazon Valley, and although several attempts have been made to grow the tree in other regions they have been generally unsuccessful. However, experimental plantings of the ouriços in the Far East are said to be giving satisfactory results. The region where the castanha has its home may be roughly sketched to include practically all the lower Amazon Basin, especially north of the main river, and that part of the basin of the upper Amazon (Solimoes) as far as the upper Beni in the Madeira system, at about 13° south latitude, and the eastern section of the Acre Territory. From here the castanha territory extends northward, following the highland of the various tributaries of the Amazon. Castanha abounds in the Rio Negro and its chief tributary, the Rio Branco, and in the region above Manaos on both sides of the Solimoes for about half the distance from Manaos to the Peruvian border. This species of castanha does not occur in Peru, but another species of edible nut, sometimes classified as castanha, is exported in small quantities from Iquitos.

Throughout the wide area where castanha is found several different grades of the nut exist. On the markets of Para and Manaos they are classified according to size and are divided into three grades—large, medium, and small. The largest and most valuable grade comes from (1) the high land on either side of the Solimoes and particularly in the region of Codajaz, where the nut attains such large proportions that it is considered preferable to the nuts usually classified as "large" and is sold as "grandissima" (extra large); (2) the Rio Negro, and (3) the following areas in the lower Amazon: The high country in the municipality of Obidos, especially in the Rio Trombetas and its affluents and in the lands bordering the Maues and other streams in that section. The grade known as "media" (medium) is encountered in the greatest quantities, being common to the sections where the large grade grows and many other areas where the castanha is all "medium" and "small." Nearly all of the castanha in the lower Amazon, with the exception of that growing in the Trombetas and Maues rivers, mentioned above, is "medium" and "small." The castanha of the Acre Territory and the neighbouring region in Bolivia is also "small" (miuda.) In the upper Amazon the nuts are nearly always of the "large" and "medium" sizes, few "small" being encountered.

In the state of Para about 60 per cent. of the castanha is produced in the three municipal districts of Obidos, Alemquer, and Almeirim—all on the north side of the Amazon. In the State of Amazonas the greater part of the castanha comes from the regions of the Rios Negro, Solimoes, Purus, Medeira and Maues.

During the past two or three years production in the State of Amazonas has increased in such proportions that it is now slightly exceeding that of the State of Para.

EXPORTS OF BRAZIL NUTS FROM THE AMAZON VALLEY.
[Quantities in hectolitres of 112 pounds.]

Year.	From Para	From Manaos	Total	To Europe	To United States
1914......	130,997	198,937	329,934	135,447	194,487
1915......	63,193	79,865	143,058	74,940	68,118
1916......	74,670	124,865	199,535	77,277	122,258
1917......	188,401	148,303	336,704	43,120	293,584
1918......	79,638	64,580	144,218	31,483	89,087
1919......	221,374	335,875	557,249	139,229	418,020
1920......	79,561	109,675	189,236	73,458	115,778
1921......	216,705	297,377	514,082	169,094	344,840
1922......	321,199	361,323	682,522	312,009	369,445

NOTE.—Shipments to southern Brazil were made as follows: 1918, 23,648 hectolitres; 1921, 148 hectolitres and 1922, 1,068 hectolitres.

From the foregoing table the recent rapid increase in production can be seen. The large fluctuation in the yearly production during this period is chiefly due to the labour supply, which in years when rubber paid well neglected the gathering of castanha and *vice versa*. Prices have also increased, and during 1923 the maximum price reached 100 milreis per hectolitre in the early part of the year.

The United States generally takes the greater part of the castanha exported. By far the larger portion of the consignments to Europe is destined for England. France and Germany and to a lesser extent Italy and Belgium are also purchasers of castanha. The market in the south of Brazil is unimportant.

PERIOD OF GATHERING.

The period for gathering the nuts extends generally from November until June, the greater part of the crop falling from January to March. Because of the vast areas to be covered, however, the work is usually carried on through June. In the Acre Territory and the Rio Negro region the nuts begin to fall in November, thus being ready for market over a month in advance of the nuts from the other regions. This is an important advantage for the nuts of these regions, as the Christmas season is the time when they have the greatest sale, and by hastening the gathering here it is possible to secure the advantage of the higher prices which always rule for castanha during the holiday season.

METHOD OF GATHERING.

When the castanha nut reaches maturity, the winds cause the large round hulls to fall to the ground, which they hit with sufficient impact to bury themselves well in the earth when they fall in soft soil. The work of gathering castanha from under the trees is perilous, for it is not an unheard-of occurrence for gatherers to be severely injured, at times fatally, by the heavy nuts falling from the upper part of these high trees. In order to mitigate the dangers connected with the collecting of the nuts, the gatherers set up a shack of thatched palm with a steep slope to the roof in the middle of the forest area which they intend to work. When there is little or no breeze they set out to gather the nuts already fallen. The nuts are thrown out from under the trees as quickly as possible and then gathered in baskets and carried on the backs of the gatherers to their hut. This continues until all the nuts have fallen. The workers utilise the time when the wind is so strong as to make it dangerous to go under the trees in breaking open the outside hulls with machetes and extracting the nuts contained within. These inner nuts are carried to a neighbouring stream, whence they are conveyed by canoes to the nearest shipping point, usually the "barracao" or settlement where the owner of the property resides. The gatherers are bound by the law of the region to sell their castanha only to the owner of the property on which they are found.

Before they are delivered to the proprietor the nuts are washed thoroughly to give them a clean appearance. A slightly better price is realised on washed nuts. The average daily production per man is 1½ "barricas" (1 barrica equals 120 quarts.) The maximum production per man during the entire gathering season never exceeds 70 barricas, and the average production in the castanhaes of all the workers, including the many who are physically unable to work more than a small part of the time, is not more than 20 barricas.

MARKETING.

The marketing of castanha is carried out differently from that of any other product of these regions. The nuts are sent from the barracao to the Manaos or Para markets for sale. A class of merchants known as "aviadores," or commission merchants, handle the nuts from the time they leave the barracao until they are sold to the exporters. A few of these aviadores are exporters, but the majority of them are merely engaged in buying produce from the proprietors in the interior and marketing it in Manaos or Para, where they all have merchandising establishments. They furnish the proprietors with merchandise to be sold to the gatherers and make balance payments in cash. In Para and Manaos there are brokers who negotiate sales of nuts to the exporters for the aviadores. Those aviadores who do an exporting business do not, of course, need the services of a broker but fill their foreign orders from the nuts which they have procured directly from the proprietors. The profit of the aviador is gained from his commission, generally 10 per cent., which he charges the proprietor for handling the nuts, and the profit realised on the goods he sells to the proprietor. The other expenses, involving freight, insurance, payment of the municipal tax, etc., are all for the account of the proprietor. All expenses arising from wharfage, lighterage, storage, etc., before the sale of the nuts to the exporter must also be borne by the proprietor, who is still the owner of the nuts.

The market price is fixed by auction, the bidding for the nuts being carried out in the Associaçao Comercial (Chamber of Commerce) in Para and Manaos; and the rate at which the nuts are sold, being the highest bid of an exporter, is the official quotation of the day, and the exporters must pay this rate to secure nuts with which to fill their orders from abroad.

BY-PRODUCTS.

The large outer cask of the castanha furnishes a species of oakum used widely for calking ships, while the oil extracted from the nuts serves several purposes. It gives an illuminating oil which until a few years ago was extensively used in the Amazon Valley. The oil also contains certain medicinal properties which make it useful in pharmacy. It is also used in a special form to counteract the rusting of iron. The wood of the tree is used in naval construction, although there is little castanha lumber produced, owing to the fact that the value of the lumber does not justify the destruction of the tree and the consequent loss of its produce.

PLANTATION POSSIBILITIES.

Considering the success which has attended the plantation of rubber trees it would seem that a similar success would reward the planting of castanha, yet little effort has been made to develop plantations of this tree. Up to the present there has always been a ready market for all the castanha shipped from Brazil, and with the constantly increasing imports of these nuts into the United States, England, and to a lesser extent several other European countries, it is evident that Brazil's present production will soon be insufficient to meet the demand from abroad. For this reason it would seem that castanha plantations would be in favour in Brazil, but the great inaccessible castanha areas yet to be exploited have no doubt drawn the attention of the Amazonian proprietors of land away from planting.

A plantation of some 10,000 trees near Obidos was destroyed by fire when the trees were progressing favourably. Another plantation of a few hundred trees was observed at Codajaz, on the Solimoes River above Manaos. These trees ranged in age from one to five years. The youngest were about 6 feet in height and averaged 3 inches in circumference, while those 5 years of age stood 25 feet high and averaged 24 inches in circumference. The oldest trees were in flower at the time the plantation was visited, and should reach the production stage within three or four years. The plantation had been set out on land not entirely free from inundation, although the terrain was elevated and the drainage was good. Inasmuch as the castanheira is essentially a tree of the high land, these trees would probably have progressed more favourably had the site for the plantation been located on true terra firma. Moreover, very little attention had been given to the care of the plantation, and the trees have, therefore, made no more headway than if they had developed naturally in the forest. A well-administered plantation, where proper regard would be had for the distance between the trees in planting, for the eradication of all other growths, etc., would undoubtedly show more promising results than have been obtained here.

"PARADISE NUT."

The nut known as "sapucaia" in Brazil (*Lecythis paraensis*) and "paradise nut" in the United States is little known because of the very small quantity that is produced. The sapucaia is similar to the Brazil-nut in that it consists of many small nuts which develop within a large ouriço, just as the Brazil-nut develops. In shape and taste they differ. The sapucaia tree is almost always found on the low level land of the lower Amazon. In this respect it differs from the castanheira, which, as has been noted, is always found on the high land. Small plantations of the sapucaia tree on the alluvial areas of the lower Amazon have developed very favourably. They commence to bear fruit in their fifth or sixth year.

The methods employed in the gathering and marketing of this fruit are the same as for the Brazil-nut. Much better prices are realised on the sapucaia, however, and there is always a ready market for the small amount produced. Owing to the fact that this nut commands a better price and the tree begins to bear at a considerably younger age than the castanheira, it is reasonable to suppose that plantation development would be a more attractive enterprise than the growing of castanha. In addition to its use as a food product, the sapucaia produces a yellow oil, which when fresh is used as olive oil. The principal use of the oil is in making a high-grade white aromatic soap. All the sapucaia exported proceeds from Para, and in 1921 the total amounted to 38 hectolitres, whereas the 1922 exports amounted to 124 hectolitres. The price of sapucaia is generally double that for castanha.

Journal of the Royal Society of Arts

No. 3,754. VOL. LXXII.

FRIDAY, OCTOBER 31, 1924.

All communications for the Society should be addressed to the Secretary, John Street,

3 DEC 1924

NOTICES.

POSTPONEMENT OF OPENING MEETING.

Senatore G. Marconi G.C.V.O., LL.D., D.Sc., (Chairman of the Council), has been unavoidably detained abroad on urgent business and will not be able to return to London by November 5th. The Opening Meeting which was fixed for that date has therefore been postponed. As soon as it is possible to arrange a fresh date, notice will be given in the *Journal.*

The other meetings of the Society will be held in accordance with the announcements printed in the Programme of Sessional Arrangements, copies of which have been posted to all Fellows of the Society.

PETER LE NEVE FOSTER PRIZE.

The late Mr. Reginald Le Neve Foster presented the Society with a donation of £140 for the purpose of founding a Prize in commemoration of his father, Mr. Peter Le Neve Foster, who was Secretary of the Society from 1853 to 1879.

The Council have resolved to offer the Prize of £25 for an essay on "The Effect of Trade Union Regulations on Industrial Output."

Intending competitors must send in their essays not later than March 31st, 1925, to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.2.

The essays must be typed or clearly written. They may be sent in under the author's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The judges will be appointed by the Council.

The Council reserve the right of withholding the Prize or of awarding a smaller Prize or smaller Prizes, if in the opinion of the Judges nothing deserving the full award is submitted.

GEORGE KENNETH MENZIES.
Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

COLLOID CHEMISTRY.

By ERIC K. RIDEAL, M.B.E., Ph.D., D.Sc., F.I.C.

LECTURE III.—*Delivered February 4th,* 1924

An emulsion consists of a liquid phase dispersed in another liquid phase, *e.g.*, oil dispersed in water. It is evident that we may obtain with the same pair of liquids another emulsion with inverted phases, *e.g.*, water dispersed in oil.

In preparing an emulsion by shaking up two pure immiscible liquids together, we notice that although, under favourable conditions of agitation, the solution may become turbid and an emulsion be formed, yet in a short time the emulsion breaks or separates again into two layers. By dispersing one liquid in another we increase the interfacial surface energy and although, as we saw in our first lecture, the interfacial surface energies of liquids are much smaller than between solids and liquids, yet they are frequently sufficiently great to cause separation of the emulsion unless we introduce some mechanism for the prevention of coalescence caused by the Browman agitation. Emulsions of solid paraffin in heavy oil such as vaseline may be cited as a case of apparent stability due to the slow rate of diffusion. The two general methods of stabilising dispersed solid phases were, as we noted, the introduction of electric charges or the formation of a surface film. In the case of emulsions also these methods may be employed, the lowering of the interfacial surface tension by the addition of a stabilising agent being, however, most general.

For a definite film to be formed at the interface between two liquids the stabilising agent must lower the surface tension of both liquids. We have noted that in the case of the fatty acids floating upon water the molecules in the film are orientated; thus we should expect to find that the layer of molecules of the stabilising agent, causing the film at the surface between two liquids, is likewise orientated. This conception throws a great deal of light on the conditions under which a particular liquid will become the disperse phase on emulsification.

If we consider a perfectly plane sheet of interface it is evident that if the sheet bends towards the oil layer the oil will become the internal phase. On the addition of a soap such as sodium oleate to the mixture of the two liquids, the soap goes to the interface and in accordance with our hypothesis becomes orientated there

Water.	Oil.
NaOOC	R
NaOOC	R
NaOOC	R

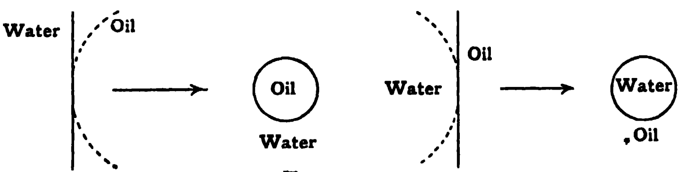

FIG. 3.

Metal Soap	Stability	Atomic Volume
C_s	8 weeks	70·6
K	8 weeks	45·3
Na	6 weeks	22·9

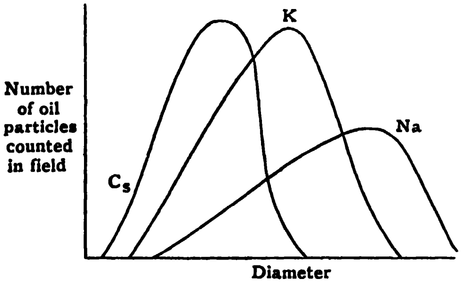

FIG. 4.

We found that the cross sectional area of the hydrocarbon chain was *ca* 21 A°; thus if the cross sectional area of the hydrated —COONa head is greater than 21 A° the molecules of the film will be more closely crowded on the water than on the oil side; thus the action of the film will be to increase the available area on the water side at the expense of a crowding in of the tails and we shall obtain an oil in water emulsion.

Although the degree of hydration, and thus the effective area of the heads constituting the metallic salts of the fatty acids, are unknown some conception of their minimum value may be obtained from a knowledge of the specific volume of the metal forming the soap. The following data of Hildebrand indicate the correlation between the stability and size of the oil in water emulsion with the atomic value of metal:

Metal Soap.	Stability.	Atomic volume.
Cs	8 weeks	70.6
K	8 weeks	45.3
Na	6 weeks	22.9

It will be noted how the curvature and the stability of the oil particles increase with increasing size of the head of the stabilising molecule.

In the case of silver oleate $VAg = 10.3$ the head is now so small that it can apparently be more easily compressed than the tail to a smaller area, and thus we obtain a very unstable (one day) water in oil emulsion.

In the case of groups of the divalent elements *Ca, Mg, Zn,* and of the trivalent ions, aluminium and iron, the cross sectional area of two and three hydrocarbon chains respectively is greater than one head, and we thus always obtain water in oil emulsions.

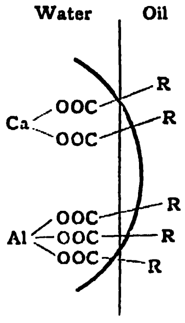

FIG. 5.

But here again the close correspondence between stability and head size as computed by means of the atomic volumes is evident.

Soap.	Stability.	Atomic value.
Ca″	1 hour	12.6
Mg″	2 days	7.0
Zn″	24 days	4.6
Al‴	7 days	3.4
Fe‴	10 days	2.3

This property of inversion of the more usual oil in water emulsions to a water in oil emulsion by the change in the stabilising agent from, say, a sodium oleate to a calcium oleate, has been made use of in a number of industrial operations, and appears to be of fundamental importance to the biologist. Lubricating oils which, as we have seen, contain small quantities of fatty acids or alkali metal soaps on admixture and dispersion with water will naturally form an oil in water emulsion, but on the addition of a trace of lime the phases will invert and we obtain a grease with oil as the continuous phase. The hard waters exert a similar action on soaps employed for washing materials containing oils, the continuous oil phase being extremely difficult to remove. Again the fact that water may be made the disperse phase and in consequence produce but little change in the appearance of the material gives us a convenient and easy method of adulteration in such substances as varied as white-lead, leather dubbing and butter.

Clowes has shown that by a suitable admixture of calcium and sodium soaps it is possible to prepare an emulsion which is practically balanced; the slightest addition of sodium soap will throw it over to the oil in water type; whilst the calcium will effect the contrary action. The balanced oil emulsion is seen from the work of Loeb and Osterhout to be of biological importance since marine organisms will apparently only flourish in solutions in which the liquids of the protoplasm are in this unstable state as regards phase inversion. It is of interest to note that the calcium sodium ion ratio in sea-water is practically identical with the ratio, formed by Clowes, necessary to prepare a balanced emulsion.

The emulsions thus require stabilising agents which naturally vary with the type of emulsion. In milk, the milk fat is emulsified in water, being stabilised by the naturally occurring albuminous substance casein, which in turn is protected by the lactalbumen. In rubber latex the hydrocarbon complex of isoprene and its homologues are stabilised by a naturally occurring protein which is apparently not without effect on the rate of vulcanisation.

In the preparation of the emulsified coal tar disinfectants the fineness of the dispersion of the high boiling point of tar acids in water, as well as their subsequent stability, depends in great measure on the nature of the stabilising agents employed, both soaps and other stabilising agents such as gelatine being employed.

Artificial milks may readily be prepared by the emulsification of 3% of oil with a stabilising agent such as the protein matter of the soya bean or the casein from skim milk, small quantities of lactose or other sugars being added to imitate natural milk.

Since the emulsoids possess a lower interfacial surface tension than the suspensoids they do not absorb ions from solution as readily as the colloidal metals, and are thus not so sensitive to precipitation. We have already noted how, by the protection of a suspension such as gold with an emulsion such as gelatine, a great enhancement in stability may be obtained.

The emulsoids are, however, by no means insensitive to electrolytes, and an emulsion will "break" and separate into its phases when the electrokinetic potential has dropped to below the critical value of ± 30 millevolts. The breaking of such emulsions is an important problem to be considered in the refining of vegetable and some mineral oils in the cream and butter industries, and in the preparation of rubber from latex, whilst the need for some test on the protection against breaking for disinfectants employed in the presence of salts is very evident.

Coalescence of the emulsoid particles may also be prevented by the addition of solids which are more easily wetted by one liquid than by the other. Thus Pickering has obtained emulsions of oil in water with basic iron copper and metal salts and more with the aid of carbon. A study of the composite nature of the mechanical skin indicates clearly that the external phase must be the one which displaces the other from the particle surface, exerting a wedge pressure similar to that exerted by the molecules of the soaps.

If we imagine the disperse phase to grow in a point will come when the spheres of the phase just touch one another. This occurs when the free space left is some $\frac{1}{3}\frac{3}{7}$ of the total volume. If the spheres were undeformable this would be the upper limit of the emulsion, but spheres consisting of a liquid can be deformed, and in fact Pickering has been able to obtain as high as 99% of disperse phase. The emulsoid thus acquires a polyhedral structure and in appearance is like a blancmange or jelly. For such emulsions in which the continuous phase is practically confined to the surface layer it is evident that the protective film must be exceedingly strong.

Before leaving the subject of the emulsoids I should like to refer to an important test which is apparently a purely colloidal reaction. I refer to the precipitation tests employed in the diagnosis of syphilis. The general method of testing for luetic serum is to compare the precipitating power of normal and luetic serum or cerebro-spinal fluid on an emulsoid termed an antigen. From a consideration of the vast number of modifications of antigens which can be employed it would appear that the precipitating reaction is in reality the result of the mutual action of an electronegative colloidal suspension with an electropositive material present in luetic serum and cerebrospinal fluid, but present in much smaller quantites in normal sera. The electro-negative antigen must be brought to the requisite degree of sensitiveness for it to come within the precipitating region of 30 millevolts on the addition of small quantities of serum. It would appear probable that as our knowledge of colloidal protection increases we should be able to prepare colloidal emulsions of the required sensitiveness without having recourse to the various complex heart extracts embodied in many of the preparations.

The jellies or greases prepared in the manner described are, however, entirely different in structure from the adsorbing jels, such as silica, alumina or ferric oxide. We have already noted that we can precipitate a substance like barium sulphate in a form which is not macrocrystalline or granular, but as a jelly containing appreciable quantities of solvent. The hydrated oxides of iron and copper can be precipitated in a flocculent form at low, and a granular form at high temperatures, even more gelatinous are the precipitates of alumina, silica and gelatine. Flocculent precipitates evidently represent a transitional stage between granular precipitates and gels, which are always prepared by methods of condensation either as the result of interaction of two reagents, or by cooling a solution containing a gel forming material of a high solubility temperature coefficient.

The gels evidently consist of two phases, one a solid and the other a liquid, and the question arises as to the structure of the solid phase. We have already noted that emulsions may be prepared in a rigid form and that these possess a honey-comb or polyhedral structure, and for a long time it was considered that such a structure must be attributed to the true gels. The gels are exceedingly elastic, a point somewhat difficult to explain if they consist of isolated spherical particles embedded in a relatively non-elastic medium; further they are relatively extremely rigid, and these and many other properties are best interpreted on the assumption that the solid phase of the gels consists of a number of particles joined together to form relatively short fibrils or threads which intersect one another in all possible directions to form a gel in the irregular meshes of which the mobile liquid phase penetrates. Under high magnification in coarse gels such as dibenzoyl cystine and some soaps the fibrillar structure can be readily observed. The X-ray examination of a number of gels including silica, stannic oxide and vegetable fibres such as cellulose and ramie fibre, has confirmed the presence of a crystalline structure in these gels.

The fibrillar structure is likewise supported by examination of the crystals of gel forming substances; they are almost invariably long and needle shaped such as benzophenone and dibenzoyl cystine molecules and can apparently hang on to one another in a series of chains; thus we can imagine a chain formation in a soap to take place by the following:

CH_3CH_2 Na
$NaOOC—CH_2CH_2—CH_3$
$NaOOC—CH_2CH_2CH_3$
$CH_3CH_2—COONa$ $CH_3CH_2—COONa$

the mutual adhesion between the non-polar and the polar ends prolonging the molecular structure.

Similarly, we may readily imagine a chain formation in the gelatinous hydroxides; thus Pauli has brought forward evidence for the existence of salts of the type

$$[Zn\,(OH)_4\,Zn\,(OH)_4\,Zn\,O\,Cl_2\,Zn\,\overset{++}{O}]\,Cl_2{}''$$
$$[Zn(OH)_4\,Zn\,O\,Cl_2\,Zn\,\overset{++}{O}]\,Cl_2{}''$$
$$[Zn(OH)_4\,Zn\,\overset{++}{O}]\,Cl_2{}''$$

Gels consisting of fine fibrils are usually dry and rigid, whilst the coarser the fibril the more moist and elastic do they become. Silica and gelatine may be cited as examples of each case. The rigid gels may be dried and the interfibrillar liquid removed without collapse, and indeed it has been found possible to replace the water in a silica gel by other liquids, such as alcohol or benzene. The interfibrillar volume and average diameter of the interfibrillar capillaries per gm. of a silica gel have been measured with the following results:

Liquid.	*In c.c. per gm. of gel.*	*δ of capillaries.*	
		Largest	*Smallest.*
Water	0,6210	54·9 A	27·5 A
Benzene	0,6270	59·8 A	27·0 A
Acetylene tetrabromide	0,6160		

The gels possess many interesting electrical properties which are of great importance in the practice of dyeing the crystalline gels, such as cotton, silk fibre and wool, and in the process of tanning.

The gel fibres are generally charged, those of wool, silk and cotton acquiring a negative charge in water; positively charged dyes of the methylene blue type will readily be adsorbed and thus effect dyeing of the fibre. In the same way many positively charged sols of the metallic hydroxides, such as aluminium, iron chromium and tin, are adsorbed and act as mordants. The fibres of silk and wool, however, appear to behave in some respects like gelatine, which we noted when discussing protection could acquire either a positive charge in acid solution or a negative charge in alkaline solutions. The most plausible assumption to explain this phenomenon is to assume that these fibres, like gelatine, contain both acid and basic groups, and are in fact amphoteric electrolytes. It is thus clear that acid as well as basic dyes can be caused to adhere to silk and wool fibres by attachment to the basic groupings which confer on the colloid its positive charge on combination with hydrogen ions. The fact that the gel fibres are charged and are in all probability highly solvated likewise gives a ready interpretation of the fact that most gels will swell when immersed in dilute acids or alkalies, but the water content is at a minimum at the isoelectric point. This has been elucidated by the work of Professor Donnan at University College on membrane equilibria. We may take as a typical instance the case of gelatine in a dilute and hydrochloric solution. Part of the gelatine G is converted into gelatine hydrochloric GH Cl, which ionises into its ions $G\overset{+}{H}\ C\overset{\prime}{l}$. The $G\overset{+}{H}$ ion, however, differs from the others in that it is immobilised, being in fact part of the gelatine fibril. We can thus represent the concentrations outside and inside the gelatine fibril diagrammatically as follows:

Inside.	*Outside.*
G	
$c\ G\overset{+}{H}$	$x\ \overset{+}{H}$
$a\ \overset{+}{H}$	$x\ \acute{C}l$
$b\ \acute{C}l$	

Under conditions of equilibrium by the law of mass action we obtain the following relationship:

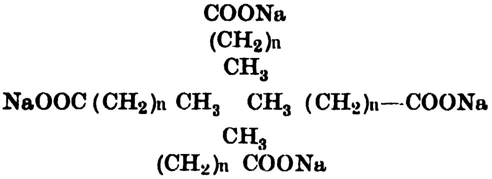
$$x^2 = ab$$

Hence since $a + b$ must always exceed $2x$ except when $a = b$, the number of diffusible ions inside the solvated gel must exceed those outside. Since the osmotic pressure is due to the diffusible ions this will be greater inside than out, causing the gel to swell until the cohesive elastic force of the fibrils just balances the difference in osmotic pressure. It is evident also that the ionic concentrations on each side of the membrane will be unequal and will give rise to differences of potential; these have been investigated by Donnan and his co-workers and the experimentally determined values agree remarkably closely with the theoretical values expected.

In addition to colloidal systems which I have alluded to during this course of lectures there is one other important class about which I should like to say a few words. I refer to the soaps, many mysteries of which have been revealed by the researches of Professor McBain at Bristol.

The soaps dissolve in alcohol to form simple solutions; in water to form colloidal solutions. The critical examination of physico-chemical properties of aqueous solutions of soap have indicated that the colloidal particles consist of an agglomeration of soap molecules containing water of solvation. These colloidal aggregates are also charged, as shown by experimental work on electric cataphoresis, but they differ from the colloidal aggregates which we have examined in the case of the more usual sols and emulsoids in that the electric mobility of the charged particles appears to be comparable to that of an ion ; and in addition the equivalent conductivity is comparable to that of an ion. This can only be accounted for on the hypothesis that the colloidal particle has undergone extensive surface ionisation ; to such particles McBain has given the very fortunate name of ionic micelle and its general chemical formula can be denoted by $(Na\ P)x\ (P')y\ (H_2O)z$.

The saponaceous character of soaps can be imparted to hydro-carbon chains by the insertion of groups such as — COO Na — SO_3 Na — $N(H_3)$ I and other similar polar assemblages and it would appear that the micellar structure and the detergent action of such substances may be attributed to the same cause, *i.e.*, the property of the non-polar hydrocarbon chains adhering to one another or to a hydrocarbon, an adherence which we can represent diagrammatically as follows :



$$\begin{array}{c} COONa \\ (CH_2)n \\ CH_3 \\ NaOOC\,(CH_2)n\ CH_3 \quad CH_3\ (CH_2)n{-}COONa \\ CH_3 \\ (CH_2)n\ COONa \end{array}$$

We have noted in our survey of the properties of colloids that the operation of forces at interfaces may produce unexpected mechanical, chemical and electrical effects, which, however, on ultimate analysis lend themselves to theoretical treatment and experimental verification. In addition we have had occasion to mention a great number of technical and industrial operations in which a proper understanding of surface phenomena is necessary before we may legitimately expect an improvement on the somewhat haphazard and rule of thumb methods frequently employed. There is, however, little doubt that the progress of industrial chemistry will in future be ever increasingly regulated by the tempo of research prosecuted in this important field of physico-chemical investigation.

NOTES ON BOOKS.

Reinforced Concrete Design. By G. P. Manning. London : Longmans, Green and Co. 21s. net.

Mr. Manning presents us with a treatise well suited for the thorough, but active and driving aspects of the present age, and in his total of 484 + XVI pages, with numerous diagrams, graphs, folders, formulæ, and labour-saving tables, our author gives us a full and concisely worded guide to the practice of the time.

A very complete mathematical study of strains, stresses, and the like is embodied in Mr. Manning's volume : and, indeed it may be considered that such study forms the ground-work of the volume, but nevertheless the student is reminded in the preface (p. V) that "long and laborious mathematical processes increase office costs, give greater opportunities for error, and discourage and fatigue the designer."

When one looks more and more closely into the details of Mr. Manning's book, its wholly and unmixedly practical character becomes increasingly manifest. We have no discursive plunges into the history of by-gone times, but we have frequent aphoristic and anecdotal cautions as to dangers and risks which beset the designer who relies too much on theory or on theory alone. This view in no way weakens our author in his thorough mathematical development of the subject even to the smallest details. On p. 468 he tells a story of six persons—he was one of them—who in a preliminary sense passed a design which lacked an essential member, and he points out how comparable blunders are to be avoided; as by frequently pausing in detail work to take general views, and also by a final broad study in which "the designer's common sense will tell him if his sizes are far wrong." As an example of our author's numerous aphorisms, we may quote from p. 402 : "Drawings and calculations should be checked over by some person who has taken no part in the preliminary designs."

Domes are dealt with at considerable length in chapter XXIV, and we learn that they have been made with a thickness as low as three inches for a dome of 50 feet in diameter. Among other subjects treated of in separate chapters are chimneys, staircases, flat-slab floors, hollow-tile floors, circular tanks, and bridges.

From the above it will be realised that Mr. Manning's thorough and comprehensive (and we may say admirable) volume is a text-book for the present generation, and in reference to our time condition of somewhat rigid standardisation as regards the cements as sold; also as to the general aspects of reinforced concrete construction. How thoroughly our author realises the present position is shown by the following on p. 468 : "Above all things the beginner must pin his faith to standard practice and to actual structures. All theories and text-books should be examined with the utmost scepticism."

It was the illustrious Smeaton and his associate Cookworthy (about 1756) who took the first notable step towards certainty as regards the composition and condition of water resisting calcareous cements ; such cements having been in use, on an uncertain basis, for about two thousand years.

Early in the 19th century M. Vicat followed in the path indicated by Cookworthy and made analyses of such limestones found in France a., were known to yield hydraulic lime. Vicat having thus noted the variable proportions of silica and alumina in the natural hydraulic limestones, he endeavoured to realise the best conditions (or constant or standard conditions) by making the required additions to fat lime, working with water into a paste, and calcining balls made of the paste. The results were so satisfactory that Vicat's cement was used on a large scale at Toulon for public works in 1819 and 1820.

Vicat, in the production of cements which were produced and used on a large scale during those years, employed all the essential features which characterise the present-time manufacture of "Portland Cement" (a term which we think is due to Aspdin), together with the very vital feature of a chemically adjusted or controlled single preparation or frit, independent of such uncertain additions as pozzolana, trass, or an artificial substitute.

The researches of Smeaton and Cookworthy are described in detail on pages 11 to 16 of the printed text of Bertram Blount's "Lectures on Cement," published in 1912 by the Institute of Chemistry, while Vicat's long period of varied labour in relation to cement is detailed in the 1881 edition of the Roret (Paris), "Manuel Complet du Chaufournier."

An Introduction to the Strowger System of Automatic Telephony. By H. H. Harrison. London: Longmans, Green and Co. 7*s*. 6*d*. net.

In his preface Mr. Harrison explains that all the systems but one are similar, so for detailed study he takes the Strowger system, this having been chosen for installation in London. Page 1 of the text embodies a mild protest against the application of the term "automatic" telephony to "an elaborate system of remotely controlled switch-gear in which the calling subscriber exercises a controlling function over centrally located switches." He also (pp. 1 and 2) favours the term "machine-switching," which has been introduced by the American communication engineers, as "more logical"; further, it "accurately defines the functions of the apparatus."

In the case of the Strowger system, which we may expect in London shortly, the removal of the telephone from its switch-hook by the calling subscriber, instead of lighting a lamp at the exchange, sets a highly complex device in motion called a pre-selector, the function of this device (p. 41, Fig. 28) being to take the first mechanical steps towards finding a clear route or path for the new call.

When the pre-selector at the Exchange has functioned and put all in readiness, the calling subscriber has discriminative or indicating work to do, the complexity and difficulty of which must vary much according to the details and magnitude of the system, and for an example of high complexity and difficulty which may arise on the London system, we may refer the reader to pp. 139-140. We fail, however, to gather from Mr. Harrison's book how the calling subscriber is made aware that the pre-selecting machinery has functioned and is ready for him, or of the probable average time required. The main duty of the calling-subscriber is to send impulses of from 1 to 10 in series, at the right time on stages by a calling-dial machine (p. 8, Fig. 8; p. 4, Fig. 32; as to lettering for routes or exchanges p. 139 and p. 141, Fig. 86. There are mechanical features of the Strowger digiting switch or calling-dial, which are worthy of mention, namely, the device for governing or slowing-down speed in passing-on impulses so that they may not be blurred into each other; also the pull round of the disc by the tip of the finger; but as regards the actual working, the instructions will probably vary according to special or local conditions, and our author's final remark on p. 1 suggests that he is by no means sure of a working altogether on the machine basis or without supervisory help, a view much emphasised by his pages (104-110) on supervisory arrangements, mainly in relation to trunk calls.

We think the position may be summarised by postulating that in a small unit, as for inter-communication in a business-house, there is notable economy and convenience in the machine-switching system (or "automatic" system); also for a village or small town, with about 500 instruments, the advantages are real, or about balanced against the disadvantages, but as the scope of the system becomes larger, the disadvantages of machine-switching may tend to increase rapidly owing to the heavy and complex duties imposed on the calling subscriber, and the increased complication of the machinery. The pending experiment in London, the most complex and difficult unit in the world, should be watched with the greatest interest, and there appears to be a general impression that the *crux* of the experiment will centre largely on the question of machine-switching as applied to metering the charges for message rates with zone variations. In America the rule appears to be the non-registration of calls on machine-switching systems, as saving time in the passing of calls. It is suggested in *Nature* (October 11th, 1924, p. 533), that a new tariff system will be proposed (indeed this seems inevitable if the subscriber has to do work hitherto done by the Exchange), but the difficulty of convincing users as to the fairness of proposals is hinted at. The wage value of a telephone operator is approximately a constant, but the wage value of subscribers' time must vary enormously, this perhaps being the economic fact that will bear on the most real difficulties in the London experiment.

We find no particulars as to the minimum possible times for passing calls under specified conditions, nor are we told by Mr. Harrison how ordinary untrained people will pass emergency calls, as police, fire or ambulance, especially in dim light.

This we may say emphatically: Every Londoner should be deeply interested in London's great experiment on mechanical telephony, and should carefully study Mr. Harrison's lucidly written and well illustrated book.

DOCK LABOUR AND DECASUALISATION. By E. C. P. Lascelles and S. S. Bullock. London: P. S. King and Son, Ltd. 10s. *net.*

Casual service, as distinguished from regular salaried (or wage) service is, in a certain sense, the subject-matter of the work before us, but the scope is pronouncedly narrow; the limitation indicated by the title being so rigidly adhered to as to make the book a study of an exception, or special instance in our social organisation, rather than a study of representative cases calculated to cast light on the general question as to the greater or less desirability of casual work as compared with regular salaried employment.

Many persons, possibly a majority, have a bias towards a kind of social stability which they expect to realise by regular wage service as against casual engagements, and by Mr. Lloyd Jones's 50 year-old principle of a minimum wage for all (*The Beehive*, July, 1874). Other workers, thinkers and economists reject the notion of social stability by the somnolent influence of fixed easy and uncompetitive conditions, and plead for wages in ratio to effort or success; as stimulating true progress and independent character, or mental freedom.

We may, however, bear in mind that very much of our national or staple work, farming for instance, is so fundamentally casual in its nature that occasions arise (haymaking for example) when every available person, whether on the establishment or not, is ordinarily pressed into service. Moreover, a large proportion of the professional work of the nation is so inherently casual in its nature, that to convert it into salaried service seems difficult or impracticable. The medical insurance scheme may be regarded as an effort in this direction.

Our authors, as far as we can gather, do not put forward any definite plea or argument against casual work in general, as contrasted with work at a fixed salary, but they aim at promoting social or syndical, or legislative action to end the stressful and wasteful competition which for seventy years or more has been a feature of the engagement of labour at the dock gates (pp. 1 and 2).

Those who compete for casual work at the docks are, speaking generally, neither those who prefer casual work as such nor standard or normal workmen, but cast-offs from various walks in life of a kind generally to be found in the more densely populated districts of our great cities, and many being within walking distance of the docks, these naturally gather together at the time when work may be expected.

The crowd, we are told (pp. 28-29), includes learned scholars, members of the landed aristocracy, discharged lawyers' clerks and wastrels from some 50 or 60 occupations, but our authors remark that very few men drift from agriculture to the docks; also that "aliens and Jews are now almost unknown in the docks" (p. 30).

We find mention of a better type in p. 47; a glass bottle maker who, as occasion offered, was in the habit of engaging himself as dock labourer, ship repairer, or canvasser. This case seems suggestive. A labour exchange room or shelter near each engaging place might allow the display of notices from employers in the neighbourhood requiring help.

The volume before us is the 74th in the series of monographs by writers connected with the London School of Economics and Political Science; Ratan Tata Foundation. Absence of illustrative historical study in reference to fundamental principles, and the remarkable views as to remedy, views which scarcely go beyond prohibition and the application of interference by irresponsible syndicalism, do not justify us in according to the present volume, the highest position in the above mentioned useful series.

As a remedy we find registration frequently referred to, and from the formal chapter on the subject, pp. 125-132, we learn that "registration" is not to be a mere listing of the names and lodgings of the poor outcasts so as to save them from needless effort and waiting, but an elaborate system, first for selection by "a joint Committee filled with a laudable zeal for decasualisation" (p. 124), and afterwards for exclusion or warning off as the Committee may decide; the first half of page 129 is worth careful study by students of economics as bearing on the suggested powers and action. On p. 98 we read about "officials of the Union, whose business it is to watch the 'calling-on' and prevent the engagement of non-Union interlopers."

SURVEY OF WORK OF THE GRANJA MODELO EN PUNO. By Colonel R. J. Stordy, C.B.E., D.S.O.

In 1920 Colonel Robert J. Stordy read a paper before the Society on "The Breeding of Sheep, Llama and Alpaca in Peru," in which he described an experiment about to be made on a wide scale by the Peruvian Government, with a view to supplying finer raw material for the textile trades. At that time the science of breeding was quite unknown in Peru; the sheep were small and degenerate from close in-breeding, and the primitive methods of the natives, who sheared with a knife or a piece of glass, did not tend to improve the quality or increase the quantity of the wool.

The pamphlet under notice gives an account of the progress that has been made during the period May, 1921—July, 1923. A consignment of livestock, including 130 pure-bred rams, 20 pure-bred Suffolk ewes, mares, shorthorn bulls etc., was exported from England in February, 1921. As their ultimate destination at Chuquibambila, is situated in the Sierra at an altitude of 12,000 feet above sea-level, it was necessary to give them a period of acclimatisation on the way. Naturally some casualties occurred both at sea and on the final stages of their journey, but thanks to the extraordinary skill and care with which they were attended, a very large percentage of the stock reached their destination in good condition.

In a great breeding experiment the period which has so far elapsed is too short to enable the results to be finally judged, but it is satisfactory to learn that the cross-bred lambs which have been already obtained show a marked improvement on the native animal, and the influence of the imported sires is much in evidence. At ages of four to six months the lambs easily outweigh their mothers, and they stand the climatic conditions quite as well as the indigenous stock. The merino cross-breds have been particularly satisfactory and have yielded some beautiful wools, which have been very favourably reported on by Professor Aldred Barker, of the Textile Department of the University of Leeds.

Not only have the sheep themselves been improved by the experiment; the native farmers and shepherds also have learned a great deal about breeding, shearing and the scientific management of stock, and there is every reason to hope that the information freely disseminated from the "Granja Modelo" will exercise a healthy influence over the whole pastoral industry of Peru. Colonel Stordy and his staff are continually experimenting with new types of fodder that can be grown in the Sierra, and some of this work seems likely to prove extraordinarily successful.

The Scottish sheep dogs which accompanied their masters to Peru have done splendidly, and, writes Colonel Stordy, "are the wonder and envy of every Peruvian farmer. All who have witnessed the dogs' intelligent working of sheep have been most anxious to become the proud possessor of one; yet when they hear terms of endearment addressed to them in the broadest Doric, such as 'Creep doun, ye fool,' 'Gie awa' oot, mon,' or 'Ca' 'way to heel, ye muckle gommerle,' the Peruvian farmer thoroughly appreciates that to own and work a dog of Scottish descent is not without its difficulties."

SOME STUDIES IN BIO-CHEMISTRY. By Students of Dr. Gilbert J. Fowler, of the Indian Institute of Science. Bangalore: The Phœnix Printing House.

This is a delightful book in all its aspects. It reflects the cordial relations between an eminent teacher and his pupils, and it gives to the world twenty-six essays for the most part on matters of fundamental importance.

Detailed or systematic research on plant physiology and kindred subjects is a leading feature of the present day in public institutions and the present volume illustrates what is being done in India.

Considering the growing importance of the lac industry it is not surprising to find that six out of the twenty-six essays bear on this subject.

On pp. 60 and 61, Mr. Sreenivasaya studies the lac insect as a capillary phenomenon, but this interesting note includes the vegetable host as a part of the dynamic system. Whether to regard lac as a by-product, waste product, or excrementary outcast of the insect, as against the view that lac is the result of normal metabolism, is the problem which Mr. C. Rama Somayajulu has set himself to solve, the practical aim being to control the quality of the product as far as may be possible (pp. 67-70). The study of Mr. Gupta on natural resins and lacs (pp. 71-77) is, like the previously mentioned contribution, largely analytical. Utilisation of secondary products, including lac-dye, is studied by Mr. Venugopalan (pp. 78-83), and although this investigator sees no hope of the historic colouring matter being again used as a staple dyeing material, he thinks that lac-dye lakes (alumina, tin) may have a future as brilliant red pigments.

Adulteration of shellac appears to be a serious matter at the present time if we may judge from Mr. Rangaswami's paper (pp. 84-90), especially the fusion of shellac with orpiment, such arsenical shellac being, it is suggested, used by confectioners in glazing their goods and in brewing establishments for lining the fermentation tanks.

The secretion of the lac insect in relation to symbiotic fungi is studied by Mr. S. Mahdihassan (pp. 187-190). He mentions two insects found in Mysore, whose secretion does not melt like ordinary shellac, and he includes these in his study. We gather that he believes the secretion products of lac insects generally bear a direct relationship to their symbiotic fungi, but the further elaboration of these studies requires a rather thorough correlation of data collected by the chemist, the entomologist, and the botanist.

Vinegar, leather, cotton, fermentation-acetone, alcoholic-fuel, and other subjects come under consideration in the volume before us, but we have selected the work on shellac in our endeavour to give some faint notion of the class of research now in progress at the great Indian station.

MERCANTILE MARINE CONSTRUCTION.

MOTOR VESSELS.

In the last annual report of the Chamber of Shipping of the United Kingdom, it is pointed out that from the technical point of view, the most notable development has been the accelerated construction of motor ships. Of the motor ships afloat when the report was written, aggregating 1,321,131 tons, 374,873 tons were recorded in June, 1923, as being under the British flag; while at the end of the year 55 vessels of 323,041 tonnage which awaited internal combustion engines were under construction in the shipbuilding yards of this country. "That," say the Council, "is a larger amount of shipping of this type than is being built in all the other shipyards of the world." Returns for the last quarter show that at present there are 43 oil tankers being built here and abroad. Of these, 32 of 133,820 tons are under construction in Great Britain and Ireland, and 11 of 95,500 tons in Germany. The total tonnage of the motor ships under construction at the end of September, 1924, in Great Britain and Ireland was 387,670 tons, representing nearly 36 per cent. of the steam tonnage being built. For all the world the percentage was nearly 58. Taking Germany, Denmark and Sweden together the proportion was nearly 78 per cent.

British shipping, it is stated in the Chamber of Shipping report referred to, is still the most efficient instrument of transport, whether judged by the volume or quality of its tonnage. In June, 1914, 18,877,000 tons (gross register) of shipping were under the British flag, and, in spite of the heavy losses sustained during the war, the amount of shipping at the end of 1923 was larger than it was in 1914 by 200,000 tons, while in the British Dominions the increase had been as much as 812,000 tons. Of the expansion of merchant shipping of all nations which has occurred since the early summer of 1914, amounting in the aggregate to nearly 15,500,000 tons, shipowners in the British Empire were responsible for only just over 1,000,000 tons; the principal contribution to the existing surplus was made by the United States with 10,500,000 tons, while Japan added 1,760,000 tons to her fleet, Italy 1,360,000 tons, France 1,347,000 tons, Holland 1,135,000 tons, and the Scandinavian countries—Norway, Sweden and Denmark—628,000 tons.

In these circumstances the percentage of seagoing shipping of the world owned in the United Kingdom had decreased from just under 44½ per cent. to just under 33 per cent. But these figures, it is explained, cannot be accepted without qualification as indicative of the position of British shipping. Probably half of the 15,500,000 tons might be regarded as obsolete or otherwise uneconomical. The tonnage idle was more than at any pre-war period. At least 6,000,000 tons of shipping under foreign flags was estimated to be unemployed when the report under notice was prepared. Of this huge total two-thirds or more was American, whereas only 750,000 tons was British, "notwithstanding that British shipping is not artificially assisted by subsidies or sheltered by flag discrimination from unrestricted world competition."

The following table shows the tonnage of merchant vessels of 100 tons gross and upwards launched in Great Britain and Ireland, the United States (Coast), Japan and the rest of the world from 1913 to 1923:—

Year	Great Britain & Ireland.	U.S.A. (Coast.)	Japan.	Rest of the World
1913	1,932,153	228,232	64,664	1,107,883
1914	1,683,553	162,937	85,861	920,402
1915	650,919	157,167	49,408	344,144
1916	608,235	384,899	145,624	549,322
1917	1,162,896	821,115	350,141	603,634
1918	1,348,120	2,602,153	489,924	1,007,247
1919	1,620,442	3,579,826	611,883	1,332,398
1920	2,055,624	2,348,725	456,642	1,000,675
1921	1,538,052	995,129	227.425	1,581,073
1922	1,031,081	97,161	83,419	1,255,423
1923	645,651	96,491	72,475	828,564

THE CO-OPERATIVE MOVEMENT IN DANISH AGRICULTURE.

In view of the interest recently manifested in Danish Agriculture, the following notes on the co-operative movement in Denmark, taken from the annual Report by the Commercial Secretary at the British Legation, Copenhagen, may be found of interest:

The first supply association was founded in a Danish town in 1866, and was based on the supply of goods to the working population at market prices, and the distribution of profits in proportion to the value of the goods purchased. In the course of time the movement spread and there are now some 2,000 supply associations throughout the country, both in the towns and in the rural districts, with a membership of about 350,000.

In connexion with these supply associations, a "Joint Association of Denmark's Supply Associations" was founded in 1896, for the purpose of making the wholesale purchases for the various supply associations. In the course of time this central association founded a number of industrial undertakings (tobacco, chocolate, soap, margarine, bicycles, rope, knitted goods, leather and footwear, certain kinds of iron goods, and chemical technical articles) for the supply of the goods required, the turnover of these factories amounting in 1921 to Kr. 35,000,000, while in the same year the turnover of the joint association totalled some 175,000,000 kroners.

In 1898 was founded a Co-operative Fodderstuff Purchasing Association, and now between 35 and 40 per cent. of the country's imports of fodder stuffs (oilcake, maize and particularly in 1923, barley) are handled by such associations. Similarly, the Danish Co-operative Fertiliser Association (founded in 1901), supplies fertilisers to some 1,600 local societies throughout the country, with a membership of about 80,000 farmers. The central institution purchases and distributes to the member societies, on the basis of mutual guarantee, the extent of which is dependent on the size of the agricultural district in question.

Other articles required by the agricultural community are handled on co-operative lines, of which mention may be made of fuel and seeds.

The application of the co-operative principle to agriculture is, in Denmark, most characteristically shown in producing associations—co-operative dairies, "slaughteries" and egg collecting associations.

The Danish Co-operative Dairy Association was founded in the eighties with the object of extending to the smaller farmers the advantages to be gained from the production of milk in bulk, by improving the level and quality. The method employed is for a number of farmers in a district to combine to erect a dairy, the capital for the construction being advanced by a local bank on the basis of the absolute liability of the interested parties. In this manner upwards of 14,000 co-operative dairies have been erected in the country which to-day handle nearly 80 per cent. of the milk output, amounting to some 3,500,000 tons per annum. The farmers, who are bound to deliver all their milk to the dairy of which they are members, are paid by the dairies on what amounts in practice to the actual butter fat contents of the milk delivered. The dairies pay all overhead charges, such as transport, so that in this respect all the members of a dairy are equally placed, whether their farm lies far from or near to the dairy. Of the butter produced in these dairies, some 30 per cent. is moreover sold by the Butter Export Association, the remainder being handled by private firms.

The 46 co-operative "slaughteries," founded on similar lines, now handle about 90 per cent. of the total bacon production of the country. The output is mainly sold through British firms, but one co-operative selling association exists comprising nine "slaughteries." The co-operative "slaughteries" also interest themselves in the improvement of the stock by the establishment of stud farms and the publication of pedigrees, etc.

As regards eggs, the Danish Joint Egg Export Company has a membership of about 500 egg associations throughout the country with some 50,000 members. These members are bound to deliver eggs stamped so that they can be traced back in case of complaint.

Further, a Joint Cattle Export Association exists embracing a number of local associations throughout the country, the members undertaking that their sale of cattle, outside their own district, shall be made through the association. The cattle in question are delivered to the society on a fixed day in the week, and the farmer receives the estimated value, less a small working commission to the association. The cattle are then sold by the association, at the best terms obtainable, and at the annual balancing of the books, the profits or losses are divided among the members in proportion to the number of beasts delivered throughout the year. (*Mutatis mutandis* a similar procedure is followed by the other co-operative selling associations, the seller receiving an amount based on periodical quotations at the time of delivery, and a share of the year's profits *pro rata* of his deliveries.)

The co-operative system is also applied in many other directions, indeed, there is practically no aspect of agricultural life in which, in some degree or other, co-operation has not been called upon to play a part. A cement and a machinery factory, electric power stations, various forms of insurance and finally a joint stock bank, with branches throughout the country, may be mentioned. In 1921 this bank had a turnover of Kr. 11,500,000, while the annual turnover of the various co-operative concerns (apart from the bank and the power stations) is estimated at about Kr. 1,500,000,000.

The question of the establishment of a shipping concern by the co-operative producing associations has recently been revived, but no definite decision has as yet been reached in the matter.

SMOKELESS FUEL.

The Department of Scientific and Industrial Research is empowered to test at the public expense plants for the low temperature carbonisation of bituminous coal. Such a test on "Parker" plant took place at the works of the Low Temperature Carbonisation Company, Barugh, Barnsley, during July last, and an elaborate report on the operation signed by the Director of Fuel Research, Dr. C. H. Lander, has been published under the authority of H.M. Stationery Office. In a prefatory note it is pointed out that no attempt is made to pronounce on the commercial possibilities of the plants tested. "The likelihood of commercial success can only finally be judged after working a plant under a steady load for a long period, and in the light of complete knowledge of local conditions, such as cost of raw material, quantity of raw material available, price and markets for products, cost of labour, etc."

The plant available at Barnsley consisted of two units, each capable of carbonising 50 tons of coal per 24 hours, and the test was carried out by the staff of the Fuel Research Station on one of these units, after it had been in continuous operation for eight days, on Dalton Main coal. After observation of the working of the retort for 48 hours had shown that steady conditions had been obtained, a test was started in which it was intended that over 100 tons of coal should be carbonised. This test, however, had to be discontinued owing to a breakdown of the exhauster plant, and on restarting shortage of coal necessitated the restriction of the test to 92 tons of coal. The coal employed was Dalton Main (Rotherham) coal, with which the Fuel Research Station has had considerable experience.

During the test samples were taken of the coal and of the products of carbonisation while the conditions of working and the labour required were carefully noted. The samples collected were all reduced as far as possible and brought to the Research Station for examination. In order to determine whether the test had been a satisfactory one a weight balance was prepared and found to show a loss of 0.48 per cent. "This, in conjunction with the thermal balance loss of 5.2 per cent., may," says the Report, "be regarded as very satisfactory."

The yields of products per ton of coal carbonised were as follows :—

Coke, 13.92 cwt.
Gas, 5,620 cu. ft., or 39.6 therms.
Tar, 18.62 gallons.
Liquor, 26 gallons.
Crude spirit, 1.78 gallons.
Ammonium sulphate, 13.55lbs.

The coke or smokeless fuel produced was of a very suitable size (1 in. to 3 in. pieces). It was not friable, and contained only 4.6 per cent. of breeze. Analysis showed that it contained rather a low percentage of volatile matter (approximately 4 per cent.). When burnt in a household grate it was readily ignited and gave a good hot fire. This fire showed less flame than the coke cakes as manufactured at the Research Station, as was to be expected from its low content of volatile matter.

The yield of tar was high, representing 68 per cent. of that obtained in the assay apparatus. On examination this tar proved to be a normal low-temperature tar. The yield of gas was fairly high, and throughout the test varied considerably both in volume and in calorific value, owing to variations of pressure in the hydraulic main. The yield of ammonia was also fairly high. The liquor was, however, less than 6oz. strength, and it is questionable whether so dilute a liquor would justify recovery. The spirit obtained by scrubbing the coal gas amounted to 1.78 gallons per ton of coal.

The temperature of carbonisation was not uniform throughout the setting, varying from 600 deg. C. to as high as 800 deg. C. Suggestions are given in the Report for the improvement of temperature control. The amount of fuel consumed in the setting was excessively high owing to this high temperature, to insufficient heat insulation, and to badly designed combustion chambers. There is no doubt, the Report states, but that the 83.5 therms consumed per hour could be reduced considerably.

The conclusions officially drawn from the report are as follows:—

1. The throughput of the plant with all retorts working would be 50 tons per day (32 retorts), and would be in accordance with that claimed.
2. The products obtained were satisfactory in quantity and quality. The yields were on the average slightly better than those which have been obtained with similar coal on an intermediate scale at H.M. Fuel Research Station.
3. Certain defects in the plant showed themselves during the course of the trial, but it is considered that there should be no difficulty in overcoming these defects in future designs.

PINEAPPLE INDUSTRY IN SOUTH AFRICA.

South Africa is reported by the United States Trade Commissioner at Johannesburg to possess the largest industry in the British Empire for the growing and packing of pineapples. Like most fruits of a tropical or semi-tropical character, pineapples thrive in Natal, the eastern part of the Cape Province, and in certain parts of the Transvaal. The principal area, however, is in the eastern part of the Cape Province, where climatic conditions are most favourable.

The last agricultural census was taken in 1921, when there were 5,911 acres under pineapple cultivation in the Union of South Africa. In the Cape Province the area was 3,924 acres; in Natal, 1,875 acres; and in the Transvaal, 112 acres. These districts have, however, expanded considerably during the past three years.

In the Langholm estates (Cape Colony) alone, it is reported that 8,000 acres are to-day under pineapple cultivation, which is an indication of the expansion in the Cape Province. This vast plantation is served by eight miles of private railway line, which join on to the main line to Port Elizabeth, where the company which acquired the Langholm estate several years ago and which consumes its entire production of pines, has its factory.

Tinned South African pineapples are now on the English and Continental markets and have even found their way, in small quantities, to the United States and Canada. Four different pineapple products are tinned at the Port Elizabeth plant, namely, sliced, broken slices, crushed, and grated.

Extensive buildings have been designed for further expansion of the factory at Port Elizabeth to meet the growing output from the Langholm estates. The tin-making apparatus, it is reported, is capable of turning out 25,000 tins a day, and the plant now in use for cleaning, shaking, and cooking the pineapples is capable of dealing with 100 tons of pineapples daily.

It is believed that this industry will continue to progress fairly rapidly, as new markets are now being found (especially in Europe) for South-African pineapples. There is also the local market to develop, which up to this time has hardly been touched. The greater proportion of the high-grade tinned pineapples has been exported overseas, while the establishment of a local market has received little attention up to the present.

In view of the fact that climatic conditions are very suitable in the Cape Province and that the principal tinning factory has more or less guaranteed to purchase from farmers all the pineapples of a certain grade that they can produce, it is very likely that this industry will continue to expand, especially in that Province.

NORWEGIAN WHALING INDUSTRY.

The following table showing the yield of oil obtained by the Norwegian whaling industry in 1923, as compared with 1922, is taken from the annual report by the Commercial Secretary to H.M. Legation at Christiania:

	1922. Barrels.	1923. Barrels.
West Coast of Norway	5,000	8,510
Faroe Islands	4,000	5,852
Iceland	3,050	—
South Georgia	96,000	145,907
South Shetland ..	187,000	187,187
South Orkney	—	13,700
African Coast	20,000	38,885
Spain	22,940	36,506
Greenland	4,300	1,000 about
Newfoundland ..	—	1,600
Total	342,290	439,147

Journal of the Royal Society of Arts.

No. 3,755. VOL. LXXII.

FRIDAY, NOVEMBER 7, 1924.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.2.

6 DEC 192
A.R.I.B.

NOTICES.

NEXT WEEK.

Wednesday, November 12th, at 8 p.m. (Ordinary Meeting.) Colonel R. E. Crompton, C.B., R.E., M.Inst.C.E., M.I.E.E. etc., "The Motor Car: its Birth, its Present, and its Future." Mr. Alan A. Campbell Swinton, F.R.S., Vice-President of the Society and Member of the Council, will preside.

PETER LE NEVE FOSTER PRIZE.

The late Mr. Reginald Le Neve Foster presented the Society with a donation of £140 for the purpose of founding a Prize in commemoration of his father, Mr. Peter Le Neve Foster, who was Secretary of the Society from 1853 to 1879.

The Council have resolved to offer the Prize cf £25 for an essay on "The Effect of Trade Union Regulations on Industrial Output."

Intending competitors must send in their essays not later than March 31st, 1925, to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.2.

The essays must be typed or clearly written. They may be sent in under the author's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The judges will be appointed by the Council.

The Council reserve the right of withholding the Prize or of awarding a smaller Prize or smaller Prizes, if in the opinion of the Judges nothing deserving the full award is submitted.

George Kenneth Menzies,
Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

RECENT PROGRESS IN THE WOOL INDUSTRIES.

By Aldred F. Barker, M.Sc.

Professor of Textile Industries, University of Leeds.

Lecture I.—*Delivered 3rd December,* 1923.

Recent progress in the Wool Industries may conveniently be studied under two heads: Raw Materials and Processes. This evening I propose dealing with the raw materials only, leaving the processes of manipulation to be dealt with next week. Before dealing with the more recent developments in sheep-breeding and wool-growing, a brief review of the progress made during the past hundred years may usefully be considered. Going back to the year 1820, it is interesting to note that both at home and abroad much attention was being given to sheep-breeding, particularly from the wool point of view. Both at home and abroad it would seem that the stimulus was the importations of merino rams from Spain. Perhaps even these importations may be traced to an earlier search for better wool-producing sheep, as some years previously the Dishley Leicester had been developed, and in several parts of the British Isles this line of improvement was being followed. But the more one becomes acquainted with what was going on in sheep-breeding circles at this time, the more one is impressed with the fact that the merino sheep and its possibilities was almost invariably the stimulus. Records still exist of this sheep being tried even as far north as the Lowlands of Scotland, and it is quite evident that the Ryeland and other Down sheep of to-day still carry the merino imprint.

The development of the merino in Australia by Captain Macarthur, of Camden Park, and the Rev. Richard Marsden is in itself almost a romance of the wool industry. From observations made in the Sydney Museum the suggestion arises that attention was first drawn to Australia as a wool-providing country owing to the accidental Mendelian dominance of the merino sheep over the East Indian (and many other) sheep. A merino ram crossed on to an East Indian ewe will apparently give progeny exhibiting marked merino wool characteristics and this—which we now recognise as Mendelian dominance—apparently caused the early settlers in Australia to think that the environment was causing a change in the wool of the very ordinary sheep towards the merino wool. This suggestion was a very happy one as matters turned out, for the determined opposition of Sir Joseph Banks to the proposals of Captain Macarthur would almost certainly have held back the development of Australia as a wool-growing continent for many years, but for the faith of the early settlers. Special recognition must be given to the manner in which Captain Macarthur "stuck to his guns," and it must have been a great satisfaction to him to live to see the Camden Park flock and other merino flocks firmly established, and such a price as 10/4 per lb. realised for the finest qualities grown (1821).

In connexion with the manufacturing of merino wool it is interesting to note that to within a few years of the present time it has been possible to speak with manufacturers who remember purchasing all their merino wool from Spain, then some years later from Saxony and Silesia, and later still from Australia. In List I the three phases of the merino wool manufacturing trade are in evidence. Thus about 1800 Spain dominates, about 1830 Germany dominates, and from 1850 onwards both countries give way to Australia. (Cape wools became a substantial importation into Britain about 1880). Not until about 1900 did importations into Britain from South America attain to large proportions. It would thus seem that Saxony and Silesia drew upon and utilised to the full the Spanish merino sheep some little time before Australia got going (probably about the time that we failed to utilise the merino sheep in its pure form in this country), but that their comparatively small production, about 1850, was swamped by the superabundance of Australian merino wool.

The Cape, about the same time as Australia, had the opportunity of introducing the merino, but either the conditions were not so favourable or there were not the sheep-breeders with the vigour of the Australian sheep-breeders. Although the Cape has for many years sent to this country non-felting and snow-white merino wools, it was only just prior to the War that a really strong endeavour was made to utilise to the full the apparent possibilities of vast stretches of land for merino sheep rearing. It would appear from recent evidence that South America had received the merino sheep from Spain earlier than either England, the Cape or Australia: the non-progressive attitude of the Spanish settlers, and probably the Spanish and British animosity, must be blamed for a better use not having been made of this.

Development and changes in the sources of the World's Wool Supply.

IMPORTATIONS INTO GREAT BRITAIN.

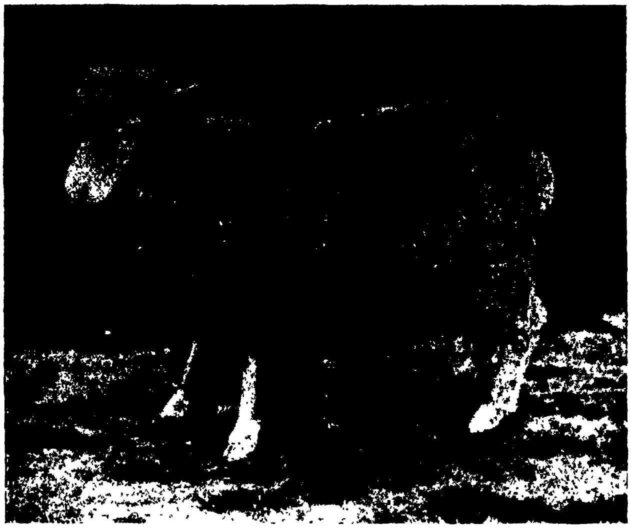

FIG. 1. CAMDEN PARK MERINO.

Evidence has recently been obtained showing that the bases of the merino flocks in Australia and South America were practically identical. In Fig. 1 is given a photograph of a Camden Park merino ewe taken in 1923. This merino is said to be pure-bred from the strain introduced very early in the 19th century by Captain Macarthur. In Fig. 1A is given a photograph of a Peruvian merino ewe imported into this country (a gift from Colonel Robert Stordy) in 1923. The two ewes appear to be almost identical, while a typical Ryeland ewe might well pass muster with either.

FIG. IA. PERUVIAN MERINO.

When dealing with South America, particular reference must be made to the Falkland Islands, where, under British stimulation, splendid flocks of sheep, based upon British Down types, have been developed. Thus Falkland wool is very consistent in possessing those crisp qualities specially associated with such wools as Shropshire, Southdown, etc.

In view of our latter-day knowledge of genetics it is interesting to note how Darwin's demonstration of the principle of the natural selection of favourable varieties has affected sheep-breeding. The appeal to the sheep-breeder was so direct that he may almost be charged with too slavishly accepting this as the only basis worthy of his consideration from a practical point of view. There are several references to sheep sports (or mutations) dispersed throughout Darwin literature, but it would seem that Darwin's idea that evolution was based upon the accumulation of the "fluctuation" (in a favourable direction) and not on the "sport" resulted in only casual mention of the sports which did arise, while the changes of apparently a more gradual nature were tacitly taken as proof of Darwin's idea of the "mechanism of evolution."

Fig. II. The Hornless Suffolk Sheep.

The work of De Vries on "mutations" and the rediscovery of Mendel's work in the early days of the 20th century appear to have supplied the stimulus which the coming of the merino gave a hundred years earlier. Under the stimulating influence of Professor Bateson and R. C. Punnett and the late A. D. Darbishire, some quite interesting work has already been carried out on Mendelian lines. The most picturesque experiment was first tried. The Suffolk sheep is hornless and has a jet-black glossy face. (Fig. II). The Dorset Horn is horned (both male and female) and has a pink-white face. (Fig. III). What better test of the truth of Mendel's ideas than to re-shuffle these "characters!" This was done and there seemed to be no difficulty in obtaining such re-combinations as a hornless sheep with a white face and a horned sheep with a black face. When the possibility of this re-shuffling was realised it was natural that Professor

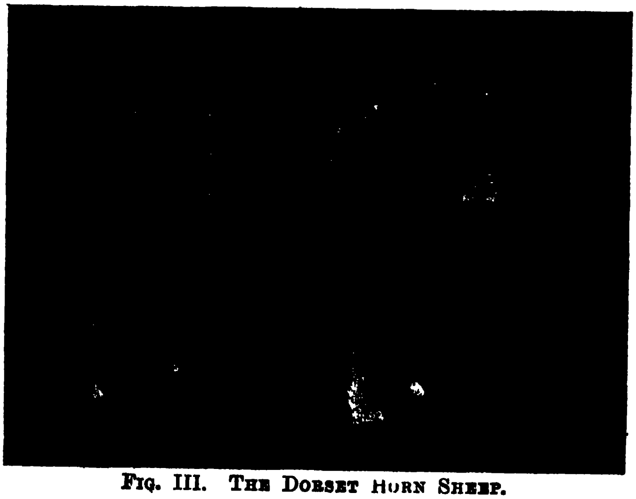

Fig. III. The Dorset Horn Sheep.

T. B. Wood, of Cambridge, who was specially interested in live-stock, should suggest that the attempt should be made to combine a good carcase character with a good wool character. For this purpose Australian merinos were mated with English Shropshires and eventually the cross-bred sheep was crossed with itself. Unfortunately only negative results were obtained—the large-bodied sheep always seemed to carry a coarse wool and the small-bodied sheep a fine wool. It would seem that with the particular individuals employed the linked characters of large body and fine wool were not a possibility, but there is some evidence that with other individuals these two characters may be linked together. The Corriedale and Polworth breeds of New Zealand and Australia would suggest that the wool may take on an intermediate character; but careful examination may show that this is not so. Sheep are built up of many unit characters and the re-combination to obtain the desired double-doses are a work of much difficulty in view of the usual impossibility of "seeing" half-doses in animals. There is no doubt, however, that the re-shuffling of characters brought so prominently to the fore by Mendelian research is likely to have far-reaching effects in the wool industry, for at least in some cases it will make possible the production of the double-purpose animal. A good example of this is illustrated in Fig. IV.

About ten years ago Professor J. Cossar Ewart, of Edinburgh University, put forth the idea that the present-day sheep was not

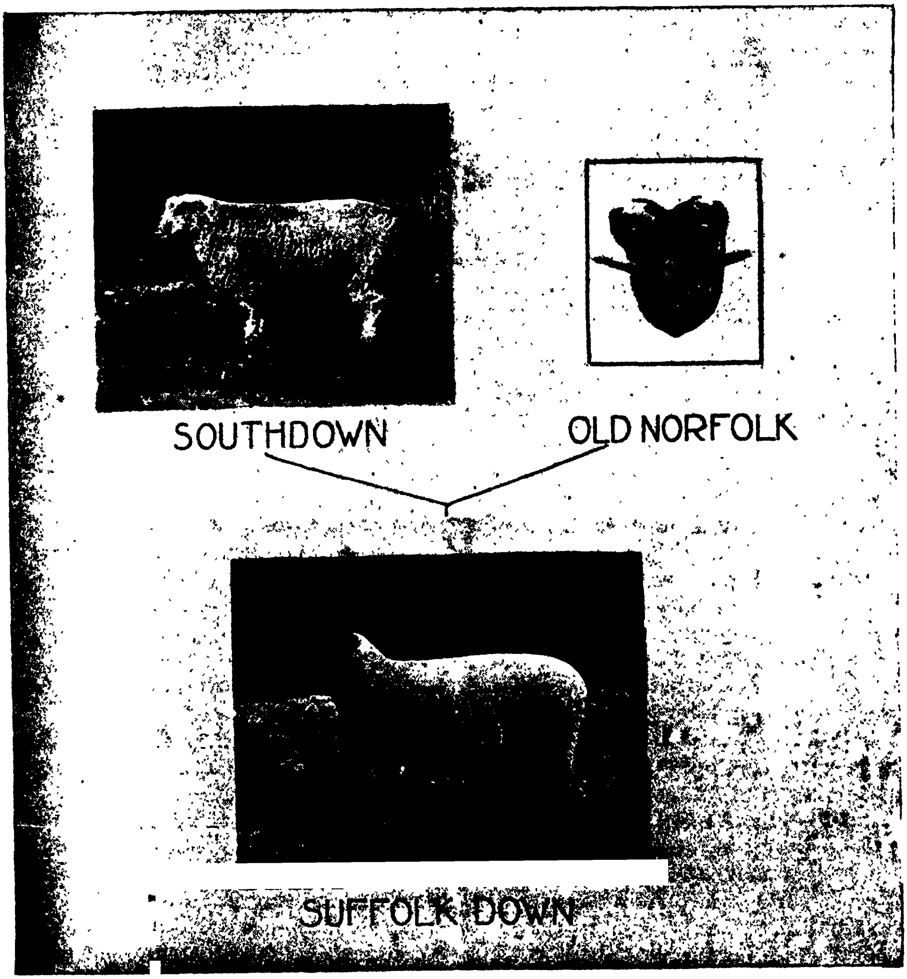

FIG. IV. ILLUSTRATING THE EVOLUTION OF THE SUFFOLK SHEEP.

descended from an unknown ancestor, but was built up on mutations from types still existing. Taking the short-tailed Soay sheep as a basis, by crossing it with the Asiatic fat-tailed sheep he showed how our present-day long-tailed sheep may have originated. Since then several examples tending to prove that this idea is correct have come to hand. In 1922, among a flock of Suffolk lambs, an almost pure fat-tailed was discovered. Again, the double coat of hair (outer) and wool (under) obtainable in the case of the wild sheep is almost invariably present in the domestic sheep. If there were an exception to this rule it would be in the case of the merino sheep, which might be supposed to have the undercoat of wool only. But this year (1923) in Australia the observation was made that all or nearly all the merino lambs examined had the double-coat, but apparently lose the outer hair coat when two or three months old. This observation has since been confirmed by Mr. Henry Robinson, of Reading Agricultural College, who reports a hair coat on most of the lambs from the Peruvian ewes presented by Colonel Robert Stordy.

In view of this work by Professor Ewart it is interesting to note that almost similar results have been obtained by Dr. J. C. Willis and Mr. G. Udny Yule, in dealing with the plants of Ceylon. When it is realised that these workers on distinctly different lines have arrived at similar conclusions, one very important question arises. If present-day variations are not descended from extinct ancestors, but are simply mutations of present-day types, then the old controversy of Special Creation *v.* Evolution is raised again, unless it should prove that in nature, as we know her, there is more than one line of evolution. If this be granted for the present period then it is further thinkable that the present-day distinct lines were evolved from one source at a far distant period.

The stimulating effect of Mendel's work is continually coming into consideration, and perhaps no more interesting case of this could be cited than the investigation at present being conducted at Leeds by the Ackroyd Fellow of the University (Mr. F. W. Dry) into the Wensleydale black problem. The typical Wensleydale blue-faced sheep produces the best lustrous wool known, this growing from the skin in long ringlet form. The sheep should have a level grey-blue face. Unfortunately this face colour is due either to a half-dose of black or to only a half-dose of black-suppressing factor: thus it is obvious that in mating such sheep many blacks are likely to crop up—from well kept records of certain Wensleydale flocks Mr. Dry places the proportion at about 15 per cent. In Wensleydale flocks at least four types of sheep are observable, viz., black (apparently a pure Mendelian recessive), silver-grey, normal and pink. The work of accounting for these types on Mendelian lines is progressing very satisfactorily, and it is thinkable that shortly methods may be discovered of differentiating the whites into heterozygous and homozygous types. From the "wool" point of view the white Wensleydale is much to be desired. Wensleydale wool gives a most beautiful waved appearance in the woven texture if this is raised wet, due to the natural ringlet form of the wool-fibre trying to re-assert itself. Much more of this type of wool will be required in the near future.

Attention may now be turned to the most recent developments in the wool-growing industry. These have followed two well defined lines, viz., developments to increase the world's supply of wool and developments to improve the quality of the wool, in view of the large demand and consequently high prices obtained for merino (*i.e.*, really of fine wool).

As already indicated, South Africa is making a very strong bid for a more important position among the world's wool-producing countries. Pedigree stock carefully selected for the prospective environment is being imported from Australia, and the figures of South African wool-production, both from the point of view of quantity and quality, will be examined with much interest by those engaged in the wool trade. Certainly African merino wools are making a name for themselves in the markets of the world.

But perhaps the most interesting development taking place at the present time is that inaugurated by the President of Peru, which is in the able hands of Colonel Robert Stordy. The base flock is the Spanish merino of a very early type (see Fig. 1A), and this is being improved in one direction towards the finer merino wool and in another direction by the introduction of British Down breeds) towards a hosiery wool of say 50s. to 56s. quality. Peruvian wools seem to possess a peculiar handle, which makes them specially valuable for certain purposes. The sheep-farms are some 10,000 feet up the Andes, but such wonderful tracts of land are available that Colonel Stordy anticipates Peru ultimately yielding about one-third the weight of the present Australian clip.

It is interesting to note that the Crown Colony of Kenya appears to have similar lands upon which sheep will thrive, and attempts are also being made there to increase the quantity and improve the quality of the wools grown.

The demand for merino wools is having a most interesting effect in both New Zealand and Australia. The tendency towards a mutton sheep or even a dual-purpose sheep is now being seriously brought into question. Thus on recently inspecting a flock of Corriedale sheep in Australia—large sheep with heavy fleeces of a medium quality of wool—the question was asked, "Would not a better financial return have resulted from a good merino strain ?" and the answer was "Yes." Now, this is due to the wonderful development of the merino in both weight of body and weight of fleece. Mr. Futter and Mr. Morrison—two of Australia's most noted breeders—recently stated in Sydney that 40% had been added to the weight of the Australian merino within the last forty years, without any sacrifice of fineness. This wonderful development of the merino must have largely suppressed the adoption of the Corriedale (Lincoln cross merino) sheep in Australia and may even attack its position in New Zealand. The most difficult thing the New Zealanders have to face, however, is the maintenance of the early maturing flocks of lambs without loss of quality in the wool; this is really a serious problem.

It is further interesting to note that in Australia attempts to increase the quantity of wool produced are also taking the line of better irrigation of desert lands and the development of the breed of sheep which makes the best use of such lands. This latter problem is by no means so easy as would appear on first thought. If, for example, a Lincoln ram be crossed on a merino ewe for producing the Corriedale type of sheep it seems that the progeny exhibit the gregarious habits of the mother (see Fig. V); while, if the cross is the reverse way, viz., merino ram on Lincoln ewe, the progeny, still exhibiting the habits of the mother, are non-gregarious, and thus make better use of any given tract of land. (See Fig. Va). This would appear to point to the "habits" referred to being inherited through the cytoplasm of the mother-cell. Unfortunately there may be greater difficulties in developing the Va type as against the V type.

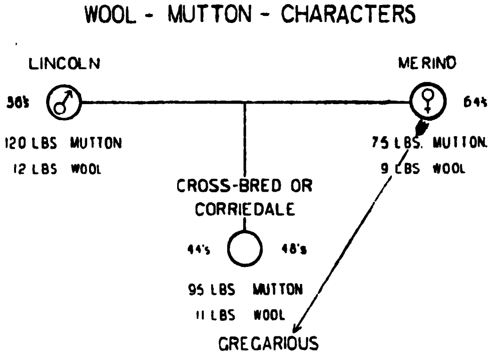

Fig. V. Lincoln and Merino, giving the Corriedale.

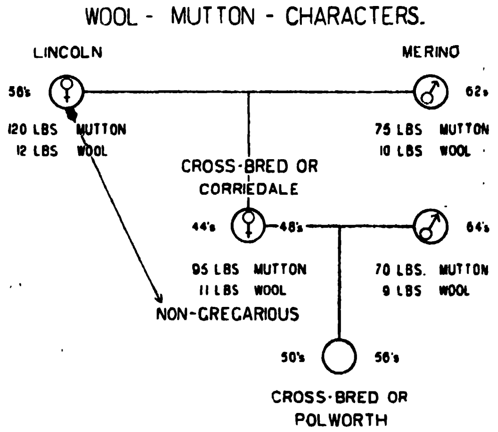

Fig. Va. Merino and Lincoln crossed Merino, giving the Polworth.

Perhaps the most interesting attempt to improve the quality of wool is that being made in Britain. Of the 100,000,000 lbs. produced by Britain, a large portion is of the rough mountain type—Herdwick Black-face, etc. A proposal to improve the mountain wools by the introduction of merino blood was put forward by the University of Leeds, and, in view of a hardy merino obviously being most suitable, the very generous offer of Colonel Stordy of some twenty Peruvian rams and ewes has been accepted, and experiments have been started which already are promising well.

Only recently one of the best known wool-staplers of Yorkshire was criticising this experiment in total ignorance of the fact that there has been a merino flock in England (inbred) during the past forty years which still maintains its physical stamina and its fine wool characteristics. In New Zealand the merinos are in the roughest part of the country and although it is known from experience that certain types of merino will not thrive in England, there is every reason to anticipate that the Peruvian merinos, both as pure-breds and half-breds, will do well.

Reference should also be made to the attempts in certain districts of India to improve the type of wool produced. It is fairly obvious that there must be many districts in India at least as suitable for sheep as the 10,000 feet districts of Peru and Kenya, and, in view of the increasing demand of India and the East for fine wool goods, it is to be hoped that every encouragement will be given to experiments leading in this direction.

Two other fibres employed in the wool industry call for special comment—the Vicuna from the Vicuna Camel of Peru, and the Ovibos fibre from the so-called Musk-Ox of the Arctic regions.

Until quite recently the Vicuna fibre could only be procured by shooting the animal, but Colonel Stordy has crossed the Alpaca with the Vicuna, and the Leeds University tests of the fibre grown by the cross-bred animal show much of it to be almost, if not quite, up to the pure Vicuna standard. A most promising development is here being taken in hand, and along with this the Colonel is also working up a white Alpaca flock and a flock giving the peculiar waved Alpaca so much sought after.

The use of the Ovibos fibre was suggested by Mr. V. Stefansson, on returning from his Arctic exploration of 1919, and only last year the University of Leeds manufactured some of this fibre into a suiting fabric which was most graciously accepted by His Majesty the King. This fibre rivals Cashmere in fineness and should it be possible to produce large quantities of it, it is assured of a place in the wool-manufacturing world. Unfortunately, this fibre is at present only obtainable by shooting the animal, and when the leader and guardian of a flock of Ovibos is shot, this means the destruction of the whole flock. The Canadian Government, however, is moving in the matter, and it may soon be found possible to maintain large flocks of these animals under semi-domesticated conditions in the northern regions of Canada. The creature itself is very fierce and would object to shearing. Fortunately, the fibre is the "under-coat," which it sheds once a year, so that this difficulty is readily surmounted. The occasional coarse strands of the "outer-coat" found with the finer "under-coat," are, however, a greater difficulty, but no doubt these may be got rid of by mechanical means, as in the case of Cashmere.

Perhaps the most serious problem to be faced is that of bringing the wool-grower and the wool-manufacturer together. The famous example of the late Sir Titus Salt's discovery, or rather re-discovery, of Alpaca should teach a lesson, but this lesson still does not appear to have been fully appreciated. Only just recently one of the roughest of British wools, then being sold for carpet yarns to America, was converted, in the Textile Industry Department of the University of Leeds, into tweed fabrics selling at seven times the cost of the wool put into them. There is a quiet work to be done here. It is hoped that eventually so close may be the association between wool-grower and wool-manufacturer that it will always be possible for the wool-manufacturer to obtain the special wool he requires and that the wool-grower will know what wools are likely to be in demand, and thus, within natural limits, will be able to produce the most useful wool and sell to the greatest advantage.

* * *

This lecture would not be complete without some reference to the several vegetable fibres which, in view of the high price of wool, are used as cheapening agents, and to the two or three types of artificial silks which have been such a marked factor in keeping the looms of Yorkshire running.

Of the first-class, flax, hemp and jute wastes may be cited. Spun with wool on the woollen principle, some extraordinarily good yarns and fabrics have been produced. The handle, however, is never that of the "all wool" nor even that of the "mungo" fabric.

At this stage reference should also be made to the recent developments in Colonial cotton-growing. Australia looks at her return of £40,000,000* for her wool clip and then at the United States' return of £400,000,000 for her cotton crop, and dreams of cotton. Although Australian cotton so far is too short for the wool manufacturer, it is possible that it may be improved in length, or it is conceivable that the provision of this cotton might release some of the longer cotton for the wool manufacturers' use.

---

* Said to be possibly £70,000,000 for the year 1924.

The artificial silks have been employed in the pure state, but more frequently with natural silk, or cotton, or wool yarns, these latter usually as warp. Most beautiful fabrics have thus been produced which redound to the credit of Yorkshire manufacturers. Perhaps one of the most difficult problems to be found has been the utilisation of artificial silk wastes. Even this is now successfully attempted. Thus the Yorkshire manufacturer, with all his shortcomings, has to his credit the first successful utilisation of many of the new fibres in the past and is still maintaining his progressive and wide outlook.

LA VIE INDUSTRIELLE EN FRANCE.

LE XIX° SALON DE L'AUTOMOBILE.

(Paris, Octobre, 1924.)

Le Salon annuel de l'Automobile s'étend actuellement sur deux périodes, car le Grand-Palais des Champs-Elysées n'est plus assez grand pour abriter la production des constructeurs français et étrangers. La première période, la plus importante d'ailleurs, réservée aux voitures de tourisme, vient de se terminer sur un éclatant succès, et près de 120 constructeurs de voitures y étaient représentés, sans parler des innombrables fabricants d'accessoires divers.

Les progrès de la construction sont aujourd'hui assez affirmés pour qu'il ne se manifeste guère de nouveautés de principe, mais les constructeurs ont encore fort à faire pour mieux étudier et généraliser l'emploi de dispositifs qui étaient, hier encore, considérés comme un luxe, et qui demain seront des organes indispensables à toute bonne voiture : démarrage électrique, freins avant, gonfleurs de pneus, etc.

Les perfectionnements aux moteurs ne s'arrêtent pas non plus, et la création récente de deux autodromes dont l'un tout près de Paris, est de nature à faciliter beaucoup la mise au point des chassis, en permettant les essais à toute vitesse, sur une piste en ciment parfaitement installée, infiniment plus commode et plus sûre que les routes publiques.

L'impression générale qui se dégage du Salon de cette année est que les constructeurs concentrent leur activité sur un nombre réduit de modèles, parfois même un seul modèle en deux grandeurs, comme Citroën qui fabrique exclusivement des modèles 10 h.p. et 5 h.p. La plupart, d'ailleurs, ont un chassis 10 h.p., qui est le plus courant et le plus demandé par la clientèle moyenne.

Comme modèle plus important et plus luxueux, on trouve, dans de nombreux stands, les chassis à moteurs de 2 litres de cylindrée, qu'on désigne plus couramment par l'expression "Chassis deux litres." Avec de tels moteurs, qui donnent effectivement une cinquantaine de chevaux, on peut circuler à 100 kilom-heure, en emmenant quatre voyageurs et en consommant 12 à 15 litres d'essence par 100 kilomètres. Un chassis de ce type pèse environ 1,000 kilogrammes. Au sujet des moteurs, il est à noter que tous les nouveaux modèles sont munis de soupapes dans la culasse, les moteurs sans soupapes conservent leurs partisans, qui sont peu nombreux, mais qui sont de premier ordre : Panhard et Levassor, notamment, n'en emploie pas d'autres.

Le nombre d'automobiles en service en France actuellement est d'environ 550,000. Il semble devoir augmenter rapidement, car la clientèle se multiplie, même dans les classes modestes. La production de l'année prochaine peut-être prévue d'au moins 200,000 voitures, dont la plus grande partie sera absorbée par la clientèle française.

CABLES TRIPHASES A ENVELOPPE METALLISEE POUR TENSIONS ELEVEES.

Un câble triphasé ordinaire comprend 3 conducteurs recouverts de papier, juxtaposés avec interposition de jute, et enfin enveloppés d'une ceinture de papier. Après séchage et imprégnation d'huile, le tout est enfermé dans une gaîne en plomb.

Le nouveau type de câble, dit métallisé, que fabriquent les Ateliers de Jeumont, en France, et ceux de Charleroi, en Belgique, est caractérisé par les perfectionnements suivants :

Chaque conducteur, recouvert de papier, est entouré d'une bande de papier doublé d'une mince pellicule d'aluminium. Les trois conducteurs sont alors assemblés, avec interposition de jute, et maintenus mécaniquement à l'aide d'une toile ; puis, après le séchage et l'imprégnation d'usage, le câble est recouvert d'une gaîne de plomb.

De nombreux fils de cuivre sont noyés dans la trame de la toile qui maintient pendant la fabrication les trois torons assemblés. Ces fils ont pour but d'assurer le contact électrique des papiers métallisés et de la gaîne de plomb, entre lesquels la différence de potentiel doit être nulle.

L'avantage que présentent ces papiers métallisés recouvrant ainsi chaque toron isolé est double :

1°—Ils diminuent la résistance thermique du câble et permettent d'accroître l'intensité de courant admissible, sans que la température de régime devienne dangereuse pour l'isolant. Ces pellicules métalliques transmettent, en effet, à la gaîne de plomb la chaleur développée par effet Joule à l'intérieure du câble. De ce fait, pour une même température de régime, la densité de courant du câble "métallisé" peut dépasser de 25 à 30 % celle d'un câble ordinaire ; 2°—Chaque conducteur

entouré de son papier et de son feuillard d'aluminium mis à la terre, constitue un câble monopolaire; or, celui-ci, sollicité par un champ électrostatique radial, présente une résistance supérieure, à égalité de fatigue, au câble triphasé soumis à un champ complexe et variable.

En outre, le champ électrostatique est limité dans le câble métallisé entre le conducteur et la pellicule d'aluminium. Dès lors, les jutes et la toile qui, même imprégnés, constituent des matériaux plutôt inférieurs au point de vue rigidité diélectrique, échappent aux phénomènes électrostatiques. De cette répartition du champ dans le câble métallisé, il résulte que l'on peut diminuer l'épaisseur du diélectrique.

Ces avantages sont d'autant plus marqués qu'il s'agit de câbles destinés à des tensions plus élevées, à partir de 30,000 à 35,000 volts, par exemple.

LES RESSOURCES DE L'INDUSTRIE PAPETIÈRE FRANCAISE.

L'industrie papetière française est fortement concurrencée par les importations étrangères, soit de papier, soit de pâte de bois, en provenance des Pays scandinaves, de l'Allemagne, de la Finlande, de la Suisse et de la Tchèco-Slovaquie.

Le total de ces importations, pour le papier seulement, dépasse annuellement 100,000 tonnes. Cette situation provient pour une grande part de ce que les papetiers francais produisent trop peu de pâte, et travaillent principalement les pâtes importées.

Pour fabriquer de la pâte à papier avec des végétaux existant en France, deux procédés ont été récemment imaginés: le traitement des pins par le sulfate de soude, et celui des pailles de céréales par le procédé au chlore et à la soude combinés.

Le procédé au sulfate de soude est excellent pour le traitement des pins maritimes, si abondants dans la région des Landes, en vue de fabriquer les papiers d'emballage, dont on importe environ 1,000 tonnes par mois en France.

L'autre procédé utilise l'électrolyse du chlorure de sodium, qui donne à la fois de la soude et du chlore, facile à transformer en chlorure de chaux: or, la soude et le chlorure de chaux sont les deux produits nécessaires à la fabrication de la pâte dite à la soude. Mais l'électrolyse donne beaucoup plus de chlore qu'il n'en faut pour blanchir la pâte obtenue avec la soude fabriquée simultanément; il faut donc, ou perdre cet excès de chlore, et alors l'opération n'est plus économique, ou l'employer accessoirement à blanchir de la pâte d'une autre provenance, ou enfin utiliser le procédé de Vains, dans lequel l'action du chlore se substitue en partie à celle de la soude, et, où, par conséquent, on emploie moins de soude et plus de chlore, ce qui rétablit à peu près l'égalité entre les productions et les consommations.

Les meilleurs résultats avec le procédé de Vains ont été obtenus, jusqu'ici avec l'alfa et avec les pailles de blé, de seigle et de riz. Or, l'alfa est abondant en Algérie, et les pailles de céréales se trouvent également un peu partout en France.

MEETINGS OF THE SOCIETY.

◆

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock, unless otherwise announced):—

NOVEMBER 12.—COLONEL R. E. CROMPTON C.B., R.E., M.Inst.C.E., M.I.E.E., etc., "The Motor Car: its Birth, its Present, and its Future." ALAN A. CAMPBELL SWINTON, F.R.S., will preside.

NOVEMBER 19.—LLEWELYN B. ATKINSON, M.I.E.E., Past-President of the Institution of Electrical Engineers, "The Scientific Principles of Artificial Incubation." EDWARD BROWN, F.L.S., President of the International Association of Poultry Instructors and Investigators, will preside.

NOVEMBER 26.—C. F. ELWELL, B.A., "Talking Motion Pictures."

DECEMBER 3.—PROFESSOR C. A. CARUS WILSON, M.A., F.R.A.S., "The Teaching of Science in Secondary Schools." SIR ROBERT ABBOTT HADFIELD, Bt., D.Sc., F.R.S., will preside.

DECEMBER 10. (5.0 p.m.).—NORMAN THOMSON, "Colombia as a Field for Development."

DOMINIONS AND COLONIES AND INDIAN SECTIONS: JOINT MEETING.

TUESDAY, NOVEMBER 25, at 4.30 p.m:—LORD STEVENSON, G.C.M.G., "The British Empire Exhibition, 1924." SIR CHARLES CAMPBELL MCLEOD will preside.

INDIAN SECTION.

Friday Afternoon, at 4.30 o'clock:—

DECEMBER 5.—LIEUT.-COLONEL R. MCCARRISON, C.I.E., M.D., B.Ch., B.A.O. (R.U.I.), LL.D., D.Sc., F.R.C.P., Indian Medical Service, "Problems of Food, with Special Reference to India." PROFESSOR HENRY E. ARMSTRONG, Ph.D., LL.D., D.Sc., F.R.S., will preside.

PAPERS TO BE READ AFTER CHRISTMAS.

SIR ERNEST RUTHERFORD, M.A., D.Sc., F.R.S., *Trueman Wood Lecture.*

SIR J. FORTESCUE FLANNERY, Bt., Past-President of the Institute of Marine Engineers, "The Diesel Engine in Navigation." LORD BEARSTED will preside.

SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S. Subject to be announced later.

MAJOR-GENERAL SIR WILLIAM SEFTON BRANCKER, K.C.B., Director of Civil Aviation, Air Ministry, "Commercial Aviation."

J. S. Owens, M.D., A.M.I.C.E., F.G.S., Superintendent Advisory Committee on Atmospheric Pollution, Air Ministry, Meteorological Office, "Modern Atmospheric Conditions."

Sir Samuel Instone, "The Thames Passenger Services."

Cedric Chivers, "Bookbinding."

Professor W. E. S. Turner, O.B.E., D.Sc., F.Inst.P., Department of Glass Technology, University of Sheffield, "The Modern Production of Sheet-glass."

C. R. Peers, C.B.E., F.S.A., Chief Inspector of Ancient Monuments and Historic Buildings. Subject to be announced later.

Lieut.-Colonel Andrew Balfour, C.B., C.M.G., M.D. (Edin.), B.Sc., D.P.H., F.R.C.P.E., "The Trend of Modern Hygiene."

Mrs. Graydon-Stannus, "Irish Glass, Old and New."

Charles A. Baker, Engineering Department, London County Council, "The Electrical Equipment of the London County Hall."

Emile Cammaerts, "The Restoration of Public Buildings in Belgium."

Lieut.-Colonel Sir David Prain, I.M.S., C.M.G., C.I.E., M.A., M.B., LL.D., F.R.S.E., F.R.S., *Sir George Birdwood Memorial Lecture,* "Government Botanical Gardens."

J. T. Marten, M.A., I.C.S., "The Indian Census."

Sir Henry Sharp, C.S.I., C.I.E., M.A., "The Development of Indian Universities."

Sir Gilbert T. Walker, C.S.I., M.A., F.R.A.S., Sc.D., Ph.D., F.R.S., "Indian Meteorology."

Sir Alfred Chatterton, C.I.E., Assoc.M.Inst.C.E. Subject to be announced later.

Hon. William G. A. Ormsby-Gore, M.P. Subject to be announced later.

Lord Blyth, "Penny Postage and Postal Communications Generally."

Brigadier-General Sir Percy M. Sykes, K.C.I.E., C.B., C.M.G., "The Heart of Asia and the Roof of the World."

Cantor Lectures.

Monday evenings, at 8 o'clock.

Louis C. Martin, D.I.C., A.R.C.S., D.Sc., Lecturer in the Department of Optical Engineering and Applied Optics, Imperial College of Science and Technology, South Kensington, "Modern Colour Problems." Three Lectures. November 24, December 1 and 8.

Lecture I.—The relations of light and colour. The physical basis of colour vision. The production of artificial daylight. Early efforts and modern improvements. The application of artificial daylight for time saving in industry.

Lecture II.—The psycho-physical basis of colour measurement. Specification of colour in terms of three variables. Colour systems and charts. Definite problems in colour measurement and their importance in Commerce.

Lecture III.—Colours of material objects. Some colorimeters and their possible accuracy. Limited range colorimeters and nephelometers. General lines of progress. Probable limitations of these methods.

V. E. Pullen, Director, Radiological Research Department, Woolwich, "Radiological Research — A History." Three Lectures. January 19, 26, February 2.

Lecture I.—Natural Philosophy. The Fascination of speculative philosophy. The border line between science and philosophy. Early natural philosophy. Development of theory. Discovery of X-rays. Controversy as to their nature. Modern theory concerning X-rays. Relation to modern atomic theory.

Lecture II.—Early apparatus. Early X-ray generators. Early vacuum tubes. X-ray tubes. Development of electrical generators. Development of X-ray tubes. The X-ray spectrometer. Measuring apparatus. Lines of modern radiological research.

Lecture III.—Early applications of X-rays. Development of medical uses. Modern applications. Physiological dangers. Necessity for protection.

Walter Rosenhain, B.A., B.C.E., D.Sc., F.R.S., Superintendent of the Department of Metallurgy and Metallurgical Chemistry at the National Physical Laboratory, "The Inner Structure of Alloys." Three Lectures February 16, 23, March 2.

Howard Lectures.

Professor John Samuel Strafford Brame, F.I.C., F.C.S., late President of the Institution of Petroleum Technologists, "Motor Fuels." Three Lectures. April 20, 27, May 4.

Dr. Mann Juvenile Lectures.

Wednesday afternoons, at 3 o'clock.

Lieut.-Colonel G. M. Richardson. Two Lectures.

Lecture I.—January 7.—"Dogs in War."

Lecture II.—January 14.—"Dogs in Peace."

(Special tickets are required for the Dr. Mann Juvenile Lectures.)

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, NOVEMBER 10 .. Geographical Society, Lowther Lodge, Kensington Gore, S.W., 5 p.m. Major R. W. G. Hingston, "Physiological Difficulties in the Ascent of Mount Everest."

Metals, Institute of, (Scottish Section), 39, Elmbank Crescent, Glasgow, 7.30 p.m. Mr. C. E. Henshaw, "An Outline of the Process of Casting in Bronze by the 'Cire Perdue' Method."

Electrical Engineers, Institution of, (Informal Meeting), Savoy Place, Victoria Embankment, W.C., 7 p.m. Mr. P. Dunsheath, "Research in the Cable Industry."

(North Eastern Centre), Armstrong College, Newcastle-on-Tyne, 7.15 p.m. Mr. S. C. Bartholomew, "Power Circuit Interference with Telegraphs and Telephones."

University of London, King's College, Strand, W.C., 5.30 p.m. Dr. R. W. Seton-Watson, "Austria-Hungary in 1867-1918." (Lecture VI.)

People's League of Health, at the Medical Society of London, 11, Chandos Street, W., 6 p.m. Sir Maurice Craig, "The Mind and What we ought to know about it." (Lecture IV., "Habit and Adaptation.")

Surveyors' Institution, 12, Great George Street, S.W., 8 p.m. Presidential Address.

Brewing, Institute of, at the Engineers' Club, 39, Coventry Street, W.C., 7.30 p.m. Mr. A. Charton Chapman, "Preservative Properties of Hops."

TUESDAY, NOVEMBER 11 .. Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 7 p.m.

Anthropological Institute, 50, Great Russell Street, W.C., 8.15 p.m.

University of London, King's College, Strand, W.C., 5.30 p.m. Sir Bernard Pares, "Contemporary Russia from 1861." (Lecture VI.)

5.30 p.m. Dr. H. W. Carr, "The Philosophy of Bergson: its relation to Past Systems and to Present Science." (Lecture VI.)

Photographic Society, 35, Russell Square, W.C., 7. p.m. Mr. L. B. Booth, "Traill-Taylor Memorial Lecture."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, Piccadilly, W., 4.30 p.m. Discussion on the "Antioch Chalice."

Asiatic Society, 74, Grosvenor Street, W., 4.30 p.m. Dr. M. Gaster, "Indian Tales in Jewish Literature."

WEDNESDAY, NOVEMBER 12 . Electrical Engineers, Institution of, (South Midland Centre), The University, Edmund Street, Birmingham, 7 p.m. Discussion on the New I.E.E. Wiring Regulations (Buildings).

Royal Academy, Burlington House, Piccadilly, W., 4 p.m. Dr. A. P. Laurie, "Early Methods of Oil Painting."

University of London, University College, Gower Street, W.C., 5.30 p.m. Mr. I. C. Gröndahl, "Nature Feeling in Norwegian Literature." (Lecture I.)

5.30 p.m. Mr. G. F. Barwick, "The British Museum Library." (I. The Reading Room.)

At the School of Oriental Studies, Finsbury Square, E.C., 5 p.m. Rev. W. S. Page, "Ballads of Eastern Bengal."

Public Health, Royal Institute of, 37, Russell Square, W.C., 4 p.m. Colonel Sir Leonard Rogers, "Leprosy as an Imperial Problem."

THURSDAY, NOVEMBER 13 .. Engineering Inspection, Institution of, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m. Mr. A. P. Welch, "The Development of Long and Short Wave Wireless Signalling."

Gilbert and Sullivan Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 8 p.m.

Aeronautical Society, 7, Albemarle Street, W. Prof. L. Bairstow, "Skin Friction."

Royal Society, Burlington House, Piccadilly, W., 4.30 p.m.

Textile Institute, 38, Bloomsbury Square, W.C., 5.45 p.m. Mr. J. S. M. Ward, "Textile Fibres produced within the Empire."

Metals, Institute of, at the Royal School of Mines, South Kensington, S.W., 7.30 p.m. Prof. H. Turner, "The Oxidation of Metals, with special reference to Thin Films."

Geffrye Museum, Kingsland Road, E., 7.30 p.m. Mr. E. Gribble, "Mediæval Woodwork."

Child Study Society, 90, Buckingham Palace Road, S.W., 6 p.m. Commandant Mary Allen, "Women Police Work among Children."

Royal Academy of Arts, Burlington House, Piccadilly, W., 4 p.m. Dr. A. P. Laurie, "Modern Pigments: their Proper Selection and Use."

University of London, University College, Gower Street, W.C., 5.30 p.m. Dr. C. Pellizzi, "La dottrina sociale e storica di G. B. Vico." (In Italian.)

At King's College, Strand, W.C., 5.15 p.m. Mr. F. J. C. Hearnshaw, "Social and Political Ideas of some Great Thinkers of the Renaissance and Reformation." (Lecture IV.) "Nicolo Machiavelli."

5.30 p.m. Mr. E. Prestage, "Luis de Camões; his Life and Lusiads."

5.30 p.m. Prince D. S. Mirsky, "The Russian Novel from Turgenev to Chekhov." (Lecture VI.)

At Bedford College for Women, Regent's Park, N.W., 5.15 p.m. Prof. W. Wilson, "Atomic Structure and Quanta."

Mechanical Engineers, Institution of (North-Western Section), Engineers' Club, Albert Square, Manchester, 7.15 p.m. (Graduates' meeting.) Mr. F. W. L. Heathcote, "Involute Gearing."

Royal Historical Society, 22, Russell Square, W.C., 5 p.m. Prof. P. Geyl, "William IV. of Orange and his English Marriage (1734—1751)."

FRIDAY, NOVEMBER 14 .. London Society, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5 p.m. Dr. S. Sunderland, "Old London's Spas and Wells."

Central Asian Society, at the Royal United Service Institution, Whitehall, S.W., 5 p.m.

Royal Academy of Arts, Burlington House, Piccadilly, W., 4 p.m. Dr. A. P. Laurie, "Painting Media: Oils, Varnishes and Tempera."

Astronomical Society, Burlington House, Piccadilly, W., 5 p.m.

Metals, Institute of (Local Section), University College, Singleton Park, Swansea. Dr. W. Rosenhain, "The Inner Structure of Alloys."

University of London, King's College, Strand, W.C., 5.30 p.m. Dr. O. Vočadlo, "Three Champions of Bohemian Reformation." (Lecture II.)

5.30 p.m. Prof. L. T. Hobhouse, "Scientific Method."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Mr. G. Avenall, "Round about Swanage."

Mechanical Engineers, Institution of (Yorkshire Branch), Philosophical Hall, Park Row, Leeds, 7.30 p.m. Eng. Vice-Admiral Sir George G. Goodwin, "The Trend of Development of Marine Propelling Machinery."

At Storey's Gate, London, S.W., 7 p.m. (Informal meeting.) Discussion on "Driving Belts and Ropes."

Journal of the Royal Society of Arts.

No. 3,756. VOL. LXXII.

FRIDAY, NOVEMBER 14, 1924.

9. DEC. 192

All communications for the Society should be addressed to the Secretary, John Str[illegible]phi, W.C. (2)

NOTICES.

◆

NEXT WEEK.

WEDNESDAY, NOVEMBER, 19th, at 8 p.m. (Ordinary Meeting.) LLEWELYN B. ATKINSON, M.I.E.E., Past-President of the Institution of Electrical Engineers, "The Scientific Principles of Artificial Incubation." MR. EDWARD BROWN, F.L.S., President of the International Association of Poultry Instructors and Investigators, will preside

CHAIRMAN'S INAUGURAL ADDRESS.

◆

The Chairman's Inaugural Address, which had to be postponed owing to the unavoidable absence abroad of Senatore Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., will be delivered on Thursday, December 11th, at 8 p.m.

The subject of the Address will be announced later.

The Swiney Prize and the medals awarded for papers read during the past session will be presented.

Tea and coffee will be served in the Library after the meeting.

REPRINT OF CANTOR LECTURES.

◆

The Cantor Lectures on "A Study of the Destructive Distillation of Coal," by Edward Victor Evans, O.B.E., F.I.C., Chief Chemist and Products Manager, South Metropolitan Gas Company, have been reprinted from the *Journal*, and the pamphlet (price 2s.) can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.

A full list of the lectures which have been published separately and are still on sale can also be obtained on application.

PROCEEDINGS OF THE SOCIETY.

◆

CANTOR LECTURES.

RECENT PROGRESS IN THE WOOL INDUSTRIES.

By ALDRED F. BARKER, M.Sc.,

Professor of Textile Industries, University of Leeds.

LECTURE II.—*Delivered 10th December,* 1923.

Having reviewed the recent progress made in the provision and utilisation of the raw materials of the wool industries, attention may now be directed towards recent progress in the processes of manufacture. Before dealing with these in detail some attention must be given to the "standard of intelligence" observable in the industry, for upon this much depends. It has been said that "the practical man is the man who perpetuates the errors of his forefathers;" and although there may be some truth in this there is more truth in the saying that "the successful man is the man who perpetuates the successes of his forefathers." In fact, so true is the latter saying that there are still many engaged in the textile industries who stake everything upon immediate and direct personal experiences, handed on, say, from father to son, and who are almost incapable of profiting indirectly from the experiences of others. Within very restricted limits these men are usually successful; and as industry in the past has been exercised within such limits, this type of man in the past has been very successful. Hence we are continually coming across the successful business man who started as the "half-timer" or at some such lowly level, and, without schooling, has risen to the top. But capacities which would score success fifty years ago are totally inadequate for success to-day: to-day the direct experiences of the large controller of industry need the flash-light of science upon them to reveal their potentialities. Further, the controller needs training in that logical and sequential reasoning which renders much more extensive lines of control easily manageable; and he also requires that immensely useful capacity of interpreting correctly and using to the greatest advantage, through his own experiences, the experiences of others, thus, perhaps, tenfolding his own inherent potentialities. To put the matter briefly, a different standard of intelligence is needed in the industry of to-day as compared with fifty years ago if progress is to be maintained. Where could the manufacturer be found even twenty-five years ago who could gain the faintest glimmering of such uses of nomography as those introduced into the University of Leeds by Dr. Brodetsky; or, what manufacturer would have considered for one moment such researches upon the evaporation of water from wool—in some cases a single wool fibre only being dealt with—as those recently conducted at Leeds by Messrs. E. A. Fisher and G. Barker? But it is possibly true that the capacity for gaining the scientific outlook required to-day is in inverse proportion to the driving-force outlook of the past—this probably explaining why, for the time being, the British manufacturer is lagging behind his continental competitor—the Frenchman more particularly. But such institutions as the University of Leeds are out to change all this. Thus, while recognising that the "researcher"—the specially gifted and well-trained man (or woman)—is to-day a necessity, it has equally to be recognised that a high standard of intelligence throughout the industry is extraordinarily important. Industry advances in broad sweeps as well as by taking new directions.

Perhaps before dealing with particular processes, the uses of the sciences—particularly mathematics, physics and chemistry—may briefly be referred to. Broadly these uses run upon two lines—(*a*) As aids to the better understanding of actual processes, and (*b*) as aids to the organisation and control of processes of manufacture.

Many facts observed in textile manufacturing cannot be understood without scientific insight, but once understood are not only more surely held, but may form the basis for further advances.

Again, any organisation other than the simplest cannot well be controlled without the use of mathematics in one form or another. If the slide rule, graphs and all systematic recording methods were eliminated, what possibilities of progress would there be to-day?

Of advances in processes which are being made to-day the following are noteworthy:—

Worsted Drawing Processes. These are now being based on the movement, control during movement, and arrangement of the fibres, composing the worsted sliver. Thus, the slow building-up of direct experience is being speeded up by scientific insight.

Twisting for (a) Fibre Control and (b) for Maximum Strength. The effects of twist are being investigated and the results so far achieved are proving most useful. Defining twist by the exterior fibre angle formed with the length of the thread, it is now possible to define within reasonable limits twists for fibre control and twists for maximum strength of yarns. Frictional co-efficients have yet to be taken into account, but already marked advances have been made in scientific yarn construction.

In yarn analysis the most useful recent discovery is the ease with which the twists in single yarns may be ascertained or defined by the accurate measurement of the expansion or contraction during untwisting or twisting. A simple instrument, based on a tenfold multiplication of the expansion or contraction of a thread, recently designed in the University of Leeds, bids fair to revolutionise single-twist testing in the works. This work had not proceeded far, however, before certain problems arose which both for their definition and elucidation required the easy use of the calculus.

Cloth Structures. If yarn structures are being more scientifically investigated, much more are cloths being so treated. Every year the tendency to regard a fabric as a "mass of balancing strains" is being emphasised, with the result that not only is the making of all the standard fabrics better understood, but ideas for new interlacings or "strainings" are continually coming up. Thus, fabric in which both warp and weft deviate from the straight line, in imitation of knitted effects, are now readily produced.

Finishing Processes: Not less interesting are the effects observed during the "finishing" operations. Examination of the wool-fibre by polarised light shows fibre-strains varying very considerably in the different wool-qualities. Thus, fibre, thread and interlacing or fabric strains have to be dealt with by the finisher and play a most important part in producing, for example, the dull, crimped surface of the "crape" cloth as against the bright, smart surface of the "satin" cloth. These strains in their various combinations are the basis of "texture," and when the French manufacturer successfully competes with the British manufacturer it is because he has taken the trouble to train himself so that he has that scientific insight which will enable him to control strains in his cloths to the very best advantage.

This problem, however, is further complicated by the vagaries of fashion so far as women are concerned. So long as the present simple dress prevails British goods will hold their own, but if—to exaggerate for a moment—the crinoline were again to come into fashion, then a fabric about one-quarter the weight per area of the present fabric would be demanded, and as the French are much finer spinners than the British, a most serious blow to British trade would follow. This, perhaps, is the tendency most seriously to be apprehended and guarded against at the present moment by the introduction of more French drawing and mule and ring spinning into the British manufacturing districts.

Mechanical Developments. The call for the same scientific insight is evident in dealing with the mechanical side of the industry as on the cloth structure side. Thus one engineer will design, say, a fancy lever for the back-rest of a loom, which looks nice, but does not act correctly; while another engineer will first clearly visualise the problem and then make the lever to give the exact effect required. Slowly, but we hope surely, our textile engineers are realising the necessity for sound theory as a basis for sound practice, and if it be still true that much spinning and weaving machinery in its design still leaves much to be desired, it is equally true that marked advances are being made.

THE DISTRIBUTION OF THE WOOL MANUFACTURING INDUSTRY.

The past, present and prospective distribution of the wool industry forms a study of quite-out-of-the-common interest. Recognising that weaving skill has come to us from the East, it is not astonishing to find after careful study that before the coming of the spinning-frame and the power-loom, skill in craftsmanship increased, as one travelled eastward. Flanders and the Rhine Valley, for example, were markedly ahead of Britain in the production of the finest and best textures, with perhaps the one or two notable exceptions where we had learnt our lesson well from our political or religious refugee teacher. Thus up to the mechanical era the line of skill seems to have been pretty much the line of the eastward migration of man, in the inverse direction.

With the coming of iron and coal, however, at least "economic production" centred in Britain and radiated outwards, naturally taking its chief line of development back along the line of migration already referred to. Whether this tendency will seriously reach so far as India, China and Japan remains to be seen. So far as the employment of mechanical means is concerned, this is already happening, and it is already thinkable that these countries may ultimately direct their known manipulative skill along mechanical lines.

But the most important migration of the mechanical industry is forward into America and to Australia. In view of the demands of the more recently settled countries for the simpler types of fabrics, this mechanical development was easily to be foreseen. Possibly an equally interesting development is that of one of the oldest of these countries—the United States of America—along the line of more complexity and greater subtlety in textile manufacturing. It is fair to say to-day that in both silk and wool America can achieve the possible—she can make the very best possible of either of these materials, although, of course, just like Europe, she does not always succeed in achieving this ideal.

Granted then that perfection of production is equally open to all, save with reference to those natural conditions over which man has little or no control—conditions which also condition those subject to them—the question may be asked, "What will be the distribution of the wool industry in the future?" Perhaps more particularly from Britain's point of view the question may be asked, "Are the agricultural tracts of the world going to manufacture for themselves, and are the specialised manufactured products of Britain going to be a drug upon the world's markets?" This latter question, and indirectly the former question, is perhaps best answered by graphing (see Fig. II) the production of the necessaries of life—food, shelter, clothing—and the interchange of certain of these necessaries on the lines of specialised production; *i.e.*, suppose in this case that Britain, man for man, can naturally produce twice as much clothing as, say, Australia, and, conversely, Australia, man for man, can produce twice as much food. Then it is obvious that anything that stands in the way of free interchange is good for neither country. But suppose that one country, say, Australia, does pass legislation which stands in the way of free interchange, then what happens to (*a*) herself and (*b*) Britain? Before adjustment takes place Australia will be producing too much food and Britain too much clothing. This would seem to be pretty much the state of things at the present moment. The adjustment will naturally be for Britain to turn some of her skilled producers of clothing into unskilled producers of corn, and for Australia to turn some of her skilled producers of corn into less productive producers of clothing—to the disadvantage of both nations, unless one of the nations is free to deal with other nations. This, of course, is the position occupied by Britain; so that it would seem that Britain's free trade policy cannot be wrong for her. On the other hand, it does seem as though legislation was actually desirable in the case of newly developed countries to "try out" if they have the capacity for economic production. If this be admitted then no better case can be cited than that of Australia attempting to manufacture her own wool into cloth—wool which otherwise must be shipped to Europe for manufacturing and then be re-shipped back to Australia as cloth. It is furthermore arguable that a country should try to legislate with the object of employing its citizens in congenial occupations, and it is thinkable that among the many migrants to Australia there will be some who best respond to the manufacturing life. But, perhaps, the question may then be asked—Would these not find their particular vocation without legislation? Possibly they would, but there does at least appear to be some excuse for legislation such as that at present being enacted by Australia.

IV WITH IRREGULARLY DEVELOPED SPECIALIZED PRODUCTION & EXCHANGE OF GOODS TOTALLY SUPPRESSED BY TARIFF
POPULATION WORKING 3/3
POPULATION FREE 0/3

FIG. 6.

The graphical method of investigating these important problems, here shown very briefly in Fig. VI, is well worth applying much more extensively, leading to clear vision with reference to such matters as the prospective re-distribution of the textile industry the world over.

In Fig. VI the basis is the production of shelter, food and clothing with reference to a manufacturing and comparatively non-food-producing country (Britain) and a food-producing and comparatively non-manufacturing country (Australia).

In I the distribution prior to specialisation of production is illustrated; each country by the work of its whole population is able to support itself with the bare necessaries of life.

In II Britain is shewn to be producing no food, but one-third of its population is producing double the clothing required. This it is exchanging for food with Australia, which is producing no clothing, but one-third of its population is producing double the food required. In this case there is no increase in the "standard of living," but one-third of the population is freed to develop the Arts of Life (or may be regarded as unemployed), or the whole population need only work two-thirds of its time, thus gaining some leisure.

In III the effects of a tariff totally suppressing exchange of goods is shewn along with the prospective advantages of specialised production. In this case both Britain and Australia are supposed to have doubled the food and clothing production, and as a consequence there is no advantage to either to exchange—in fact, it is probable that this condition would of itself, without a tariff, have resulted in little or no interchange of commodities. It will be noticed that the whole population in each country is fully employed—there being no free time and no leisured class—but both are better fed and better clothed than under I.

In IV irregularly developed specialised production is illustrated with any mutually advantageous levelling up totally suppressed by tariff. Britain is shewn as just housing herself, producing no food, but producing much more clothing than she requires (or can afford to wear), while Australia is producing four times as much food as she requires and twice as much clothing as is absolutely necessary. Thus Britain will be starving and over-clothed while Australia will be wallowing in food and well clothed. If these circumstances actually prevailed, Britain would, of course, be famine stricken and Australia would either freely send to her relief her surplus food, or, perhaps better still, remove Britain's population to Australia until the condition shown in I prevailed in Britain. This sort of adjustment undoubtedly does go on, but the fact that Britain is not yet producing food under the conditions shewn in I is suggestive.

But the question may now be asked, Will there not be over-production of clothing in Great Britain and food in Australia, and will not this naturally adjust itself by some of Britain's population going on to the land and producing food, and some of Australia's population leaving the land and becoming an army of unemployed ?

One other use of this graphical method may be noted. In III, for instance, the results of developed specialised production may be regarded as capital. Thus, under I there would be no capital but simply production and consumption from hand to mouth. This method of graphing is only partially and simply developed here, improvements and extended uses naturally suggesting themselves ; but it is possible that by this means clear vision leading to right action may be obtained where heretofore anything but clear vision, with its consequent indecisive and wavering action, has been all too much in evidence.

With the "new order of intelligence" which we see gradually taking charge of our industrial activities, we may well believe that in the future industry will more and more gravitate into the hands of the super-efficient people, and the man who to-day may boast that he can purchase for £5 all the technical skill needed, to-morrow will either have to recognise the breaking of science and scientific methods into industry, and thankfully accept the proffered assistance, or gradually submit to being beaten in the world's markets—apparently by economic conditions, but actually by the efficiency of others being matched against his comparative inefficiency. And it is not the individual expert only we require, but the intelligent rank and file, the level of intelligence of which appears to determine the level of intelligence of the controller and expert.

CORRESPONDENCE.

REPORT ON THE SOCIETY'S EXAMINATIONS.

Will you allow me to call the attention of readers of the *Journal* to some remarks of the Examiners in this excellent and useful Report, *e.g.*, "The want of intelligence on the part of the candidates in reading the questions," etc. (page

824), "the deficiency in common sense," the large number of failures in Arithmetic (Page 822), "elementary mistakes in spelling," the bad spelling of typists (page 823).

In this way the Examiners are continually emphasising the unsatisfactory state of elementary education in this country. The cause is not difficult to discover.

The teacher's time is wholly occupied in explaining away our illogical print, while he is endeavouring, contrary to natural physiological laws, to make the child do something with his hand and his eyes, contradicting that which he does with his mouth and ears. Children are born with common sense, but this is destroyed in early years by a so-called education, which costs this nation £18,000,000 a year.

If the habit of reading *out loud* the results of an arithmetical calculation were adopted in school, the absurdity of "One thousand, one hundred and thirty one million, six hundred and forty two thousand, one hundred and fifty nine pounds, twelve shillings and eight pence," as the cost of a gravelled garden path, would have been discovered by the student himself, but neither pronunciation, nor reading aloud is taught, nor can be taught without a logical notation, such as is used in music, chemistry, mathematics and all other sciences.

Oral Examinations (*page* 827).

A logical International Notation for all Speech Sounds would enable any student to read all languages at sight and to write down in a rational shorthand anything that the examiners dictate, exactly as he hears it, after which he can transcribe it into the ordinary printed form of the language used. Ordinary dictation is merely a temptation to the student to imprint upon his brain false visual impressions, in the vain hope that they may be erased by future impressions or corrections.

Unless the printer can be induced to bring his art up to date, and to write down what we say, and what we mean, there is no hope of any improvement in education, or any advance in civilisation. Professor Daniel Jones promises us new letters in three hundred years, but three hundred *days* is quite sufficient for the printer to adopt a simple international notation by means of which he can send the English language along with the commercial traveller wherever we wish to sell English manufactures.

A. DEANE BUTCHER.

NOTES ON BOOKS

EMBROIDERED AND LACED LEATHER. By Ann Macbeth. London: Methuen & Co., Ltd. 3*s.* 6*d.* net.

Leather is a very attractive material to work with, and numberless articles of use and beauty may be made out of it in one's spare time; but in spite of these points in its favour few women take up leatherwork compared with the many who spend their leisure on, say, embroidery or knitting. This is possibly because they are scared of it; the tools are unfamiliar, and they do not know how or where to start. It is for such as these that Miss Macbeth's handbook is devised. The essential tools are not numerous and are easily mastered, and the beginner will be surprised to learn with how slender an equipment work of quite a presentable kind may be turned out. Such things as hats, waistcoats, bags, blotters, gloves, etc., may be produced by any one who will follow the instructions given in this book.

It is hardly necessary in this *Journal* to labour the advantages of any handcraft. The person who has designed and executed a piece of work, however simple, has experienced something of the joy of an artist and has also rendered himself more capable of appreciating the beauties of other people's work. It is to be hoped that those who read Miss Macbeth's book will not be content to follow her instructions, but will be tempted, as she hopes they may be, to originate patterns for themselves. There is something in the very nature of leather which seems to stimulate invention; the material itself is delightful to handle; the colours are soft and harmonious, and the most pleasing results may be obtained by the most simple means. We earnestly hope that this handbook may lead to the craft being taken up much more widely than it is at present in such places as Women's Institutes, Girls' Clubs, and Continuation Schools.

MEETINGS OF OTHER SOCIETIES DURING THE ENSUING WEEK.

MONDAY, NOVEMBER 17. .. Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C., 5.30 p.m.

Arts, Royal Academy of, Burlington House, Piccadilly, W., 4 p.m. Dr. A. P. Laurie, "Methods of Wall Painting."

Chemical Industry, Society of, Joint Meeting with the Institution of Rubber Industry, at the Engineers' Club, Coventry Street, W., 8 p.m. Dr. A. Van Rossem and Mr. B. D. Porritt, "Latex: its Chemistry and the Development of its Industrial Applications."

Geographical Society, 135, New Bond Street, W., 8.30 p.m. Mr. M. W. Hilton-Simpson, "The Peoples of the Aures Massif."

Textile Institute, at the Clothworkers' Hall, 41, Mincing Lane, E.C., 5.45 p.m. Mr. H. B. Heylin, "Principles of Construction of Fabrics for particular purposes."

Faraday Society, at the Chemical Society, Burlington House, Piccadilly, W., 8 p.m. 1, Messrs. R. W. E. B. Harman and F. P. Worley, "The Hydrolysis of Alkali Cyanides in Aqueous Solution." 2, Dr. A. P. Laurie, "Note on the Expansion of Water while Freezing." 3, Mr. S. S. Joshi, "The Viscosity of Reversible Emulsions." 4 (a), Mr. D. B. MacLeod, "On the Viscosities of Liquids at their Boiling Points." (b), Mr. D. B. MacLeod, "The Kinetic Theory of Evaporation." 5, Messrs. J. T. Howarth and F. P. Burt, "New Design for Apparatus to Measure the Coefficient of Deviation from Boyle's Law, and the Determination of this Coefficient for Acetylene."

Electrical Engineers, Institution of, (Mersey and North Wales Centre), The University, Liverpool, 7 p.m. Messrs. J. D. Cockroft, R. T. Coe, J. A. Tyacke and Prof. M. Walker, "An Electric Harmonic Method of Analysis."

British Architects, Royal Institute of, 9, Conduit Street, W., 8 p.m. Mr. H. Bagenal, "Planning for Good Acoustics."

Mechanical Engineers, Institution of, (Graduates' Section), Storey's Gate, S.W., 7 p.m. Mr. L. Pendred, "The Production of a Modern Technical Journal."

University of London, King's College, Strand, W.C., 5.30 p.m. Dr. R. W. Seton-Watson, "Austria Hungary, 1867-1918." (Lecture VII.)

People's League of Health, at the Medical Society, 11, Chandos Street, W., o p.m. Sir Robert Armstrong-Jones, "Fatigue and Sleep."

East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Major-General Sir Gerald Giffard, "Some Aspects of the Future of Medicine in India."

TUESDAY, NOVEMBER 18 .. Statistical Society, at the ROYAL SOCIETY OF ARTS, John Street, Strand, W.C., 5.15 p.m. Mr. G. U. Yule, President's Address: "The Growth of Population and the Factors which Control it."

Illuminating Engineers' Society, at the ROYAL SOCIETY OF ARTS, John Street, Strand, W.C., 8 p.m. Opening meeting of the session.

Civil Engineers, Institution of, Great George Street, S.W., 6 p.m. Mr. W. J. Hadfield, "Notes on Modern Practice in Road Making."

Botanic Society, Inner Circle, Regent's Park, N.W. Prof. Bickerton, "The Forces of Nature."

Marine Engineers, Institute of, 85, The Minories, E., 6.30 p.m. Mr. J. McGovern, "The Influence of Internal Combustion Engines on the Design of Merchant Ships."

Anthropological Institute, at the London School of Economics, Houghton Street, W.C., 8.15 p.m. Capt. M. W. Hilton-Simpson and Mr. J. A. Haessler, "Native Life in the Algerian Hills illustrated by the Cinema."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Meeting of the Scientific and Industrial Group.

Arts, Royal Academy of, Burlington House, Piccadilly, W., 4 p.m. Dr. A. P. Laurie, "The Theory of Colour and its Application to Painting."

Electrical Engineers, Institution of, (East Midland Sub-Centre), The College, Loughborough, 6.45 p.m. Mr. W. Lawson, "General and Technical Ideas from the Experience of a Meter Engineer."

University of London, King's College, Strand, W.C., 5.30 p.m. Sir Bernard Pares, "Contemporary Russia from 1861." (Lecture VII.)
5.30 p.m. Miss Hilda D. Oakley, "The Philosophy of the Absolute in English Thought." (Lecture I.)

Sanitary Institute, 90, Buckingham Palace Road, S.W., 6 p.m. Miss J. N. B. Paterson "The Economic Value of the Healthy Infant and the New Zealand Welfare Work of the State."

WEDNESDAY, NOVEMBER 19 .. United Service Institution, Whitehall, 3 p.m. Colonel J. F. C. Fuller, "Progress in the Mechanicalisation of Modern Armies."

Meteorological Society, 49, Cromwell Road, S.W., 5 p.m.

Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

Microscopical Society, 20, Hanover Square, W., 8 p.m. 1. Mr. G. R. de Beer, "Comparative Histology and Cytology of the Pituitary Body. 2. Miss J. Latter, "Pollen Development in Lathyrus." 3. Dr. W. N. F. Woodland, "Some Remarkable Caryophylloeids from Siluroid Fishes of the Sudan."

Constructive Birth Control, Society for, Essex Hall, Essex Street, Strand, W.C., 8 p.m. Dr. C. W. Saleeby, "Heredity and Degeneracy—Some New Discoveries."

Arts, Royal Academy of, Burlington House, Piccadilly, W., 4 p.m. Dr. A. P. Laurie, "Some English Cathedrals and Stone Decay."

University of London, King's College, Strand, W.C., 5.30 p.m. Prof. B. O. E. Ekwall, "English Place Names." (Lecture I.)

Civil Engineers, Institution of, Great George Street, S.W. 6 p.m. (Students' Meeting.) Address by Mr. P. W. Thomas.

THURSDAY, NOVEMBER 20 .. Women House Property Managers, Association of, at the ROYAL SOCIETY OF ARTS, John Street, Strand, W.C., 5 p.m.

Royal Society, Burlington House, Piccadilly, W., 4 p.m. General Meeting to consider Annual Report of Council.

Chemical Society, Burlington House, Piccadilly, W., 8 p.m.

Linnean Society, Burlington House, Piccadilly, 5 p.m.

Antiquaries, Society of, Burlington House, Piccadilly, W., 8.30 p.m.

Mechanical Engineers, Institution of, (Midland Section), Queen's Hotel, Birmingham, 7.30 p.m. Mr. F. W. Suffield, "The Design of an Up-to-date Factory."
(North-Western Section), at the Engineers' Club, Manchester, 7 p.m. Messrs. W. S. Burge and P. J. Chittenden, "Reducing or Pass-out Turbines."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, Piccadilly, W., 5.30 p.m.

London County Council, Geffrye Museum, Kingsland Road, E., 7.30 p.m. Mr. L. A. Shuffrey, "The English Fireplace."

Electrical Engineers, Institution of, Savoy Place, Victoria Embankment, W.C., 6 p.m. Mr. G. Rogers, "Automatic and Semi-Automatic Mercury-Vapour Rectifier Substations."

University of London, King's College, Strand, W.C., 5.15 p.m. Dr. A. W. Reed, "Social and Political Ideas of some Great Thinkers of the Renaissance and Reformation." (Lecture V), "Sir Thomas Moore."
5.30 p.m. Señor O. V. Salomón, "Peru, Old and New." (Lecture I.)
5.30 p.m. Prince D. S. Mirsky, "The Russian Novel from Turgenev to Chekhov." (Lecture VII.)
At the Bedford College for Women, Regent's Park, N.W., 5.15 p.m. Lecture by Dr. J. S. Eakins.

FRIDAY, NOVEMBER 21 .. Central Asian Society, at the Royal United Service Institution, Whitehall, S.W., 5 p.m. Lord Thomson, "My Impressions of a Tour in Iraq."

Metals, Institute of (Sheffield Section), 198, West Street, Sheffield, 7.30 p.m. Mr. A. Marks, "Non-Ferrous Metals in the Foundry."

Photographic Society, 35, Russell Square, W.C., 7 p.m. Meeting of Pictorial Group.

Mechanical Engineers, Institution of, Storey's Gate, Westminster, S.W., 6 p.m. Report of Research Committee on "Marine Oil-Engine Trials."

University of London, King's College, Strand, W.C., 5.30 p.m. Dr. O. Vocadlo, "Three Champions of Bohemian Reformation." (Lecture III.)
5.30 p.m. Prof. E. G. Coker, "Scientific Method."

Shakespeare Association, King's College, Strand, W.C., 5.30 p.m. Dr. C. Sisson, "Shakespeare in the Bombay Bazaar."

TRUEMAN WOOD LECTURE (*see* "Trueman Wood")
MEETINGS, ORDINARY:—Annual report, 553
1st Meeting:—"Exhibitions," opening address by Lord Askwith, K.C.B., K.C., D.C.L., Chairman of the Council, 2
Extra Meeting:—"Amateur Cinematography," by C. E. K. Mees, D.Sc., 20
2nd Meeting: — "Téléphotographie, télautographie, télévision (avec expériences et projections)," by Monsieur Edouard Belin [Not printed]
3rd Meeting:—"Forgeries of ancient stained glass," by J. A. Knowles, 38
4th Meeting:—"The effect of sun, sea and open-air in the treatment of disease," by Sir Henry Gauvain, M.A., M.D., M.Ch., 74
5th Meeting:—"The work of the Royal Botanic Gardens, Kew," by Arthur William Hill, M.A., Sc.D., F.R.S,, F.L.S., 87
6th Meeting:—"Preservation of ancient monuments and historic buildings," by Sir Frank Baines, C.V.O., C.B.E., 120
7th Meeting:—"Cinematography in natural colours," by G. Albert Smith, 213
8th Meeting:—"The history, development and commercial uses of fused silica," by Sir Richard Arthur Surtees Paget, Bt., 33
9th Meeting:—"The earthquake and the work on reconstruction in Japan," by Iyemasa Tokugawa, O.B.E., 224
10th Meeting:—"The treatment of the death-watch beetle in timber roofs," by Prof. H. Maxwell-Lefroy, M.A., 260
11th Meeting:—"New uses for rubber," by P. J. Burgess, M.A., F.C.S., 275
12th Meeting:—"The use of vocational tests in the selection of a vocation," by Charles S. Myers, C.B.E., M.D., Sc.D., F.R.S., 291
13th Meeting:—"Building and decoration of the war cemeteries," by Major-General Sir Fabian Ware, K.C.V.O., K.B.E., C.M.G., C.B., 344
14th Meeting:—"Personal recollections of some notable scientific men," by Alan A. Campbell Swinton, F.R.S., 571
15th Meeting:—"The forests and timber supply of North America," by R. L. Robinson, Forestry Commissioner, 359
16th Meeting:—"The fishing industry and its by-products," by Neal Green, 388
17th Meeting:—"London traffic," by Sir Lynden Macassey, K.B.E., LL.D., D.Sc., 423
Extra Meeting:—"The Amazon Valley and its development," by George Macaulay Booth, 505
18th Meeting:—"The free pendulum," by F. Hope-Jones, M.I.E.E., 446
19th Meeting:—"The Victoria Dock district and its roads," by Sir Henry Maybury, K.C.M.G., C.B., M.Inst.C.E., 463
Extra Meeting:—"Photography in science, industry and medicine," by T. Thorne Baker, F.R.P.S., 495
20th Meeting:—"Wireless navigation," by J. Robinson, M.Sc., Ph.D., F.Inst.P., 516
21st Meeting:—"Furs and the fur trade," by F. C. Ingrams, 593
22nd Meeting:—(*Trueman Wood Lecture*) "The outlook in chemistry," by Sir William J. Pope, K.B.E., F.R.S., LL.D., D.Sc., 581
23rd Meeting:—"The position of the Arabs in art and literature," by Mrs. Arthur McGrath (Rosita Forbes), 649
Extra Meeting:—"Results obtained over very long distances by short wave directional wireless telegraphy, more generally referred to as the beam system," by Senatore Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., 607
Melitus, Paul Gregory, *obituary*, 302
Menzies, G. K., *disc.*, Royal Botanic Gardens, 101; *disc.*, furs and the fur trade, 603
Mercantile marine construction, 857
Meston, Lord, *chair*, manufacture of salt in India, 401, 415
Mexico, undeveloped natural resources of Quintana Roo, 534
Miller, H. E., *disc.*, new uses for rubber, 286
Miller, Sir John O., *disc.*, Survey of India, 205; *disc.*, manufacture of salt in India, 418; *disc.*, Victoria Dock district and its roads, 473
Miller, Dr. W. G., *disc.*, mineral wealth of the pre-Cambrian in Canada, 684
Milner, Viscount, *chair*, the mandate system and British mandates, 548
Mineral resources of Southern Hsinkiang, 442
——— wealth of the pre-Cambrian in Canada, *paper* by Dr. C. V. Corless, 667
Mining operations in the Rand, 857
Mint, new Chinese, 398
Mitra, J. M., *disc.*, co-operative banking in India, 388
Montagu, Hon. Stuart A. S., *disc.*, amateur cinematography, 30
Mordey, William M., *disc.*, recollections of some notable scientific men, 580
Morocco, electric power scheme in, 708
———, harbour works in, 710
———, mineral wealth of French zone, 709
———, resources of Spanish zone, 709
Motor trade of Australia, 784
——— transport in Bulgaria, 766
Murray, J. A., *disc.*, the Amazon Valley, 508
Myers, Dr. Charles S., F.R.S., *paper*, use of vocational tests, 291

N

Naval architecture, recent developments in, 802
Negro (American), vital statistics of, 32
Newcomen Society, the, 84
New Guinea, Dutch, projected development of, 738
Nicholson, Captain Colin, *disc.*, wireless navigation, 529
Noble, Saxton, *disc.*, recollections of some notable scientific men, 581
Noxon, Wm. C., *paper*, Empire settlement, 138

O

OBITUARY:—
Annual report, 567
Agius, Edward Tancred, 803
Beilby, Sir George T., F.R.S., LL.D., 706
Duke, Sir (Frederick) William, G.C.I.E., K.C.S.I., 581
Freeman, Henry Somerson, 270
Kimber, Sir Henry, Bt., 103
Maw, William Henry, LL.D., M.Inst.C.E., 319
Melitus, Paul Gregory, C.S.I., C.I.E., I.C.S., 302
Stewart-Clark, Sir John, Bt., 288
Taylor, George William, 206
Veitch, Sir Harry James, 605
Waring, Francis John, C.M.G., M.Inst.C.E., 218
Wenger, Albert Francis, 288
Ochre, French, production, 551
Oil (Empire): the progress of Sarawak, *paper* by Hon. T. G. Cochrane, 308
—— (palm) cultivation in Sumatra, 399
Oliver, Prof. F. W., F.R.S., *disc.*, the work of the Royal Botanic Gardens, Kew, 100
Olivier, Lord, *disc.*, co-operative banking in India, 381
Opium, Macedonian, 116
Ormsby-Gore, Hon. William, M.P., *disc.*, the mandate system and British mandates, 549; *chair*, recent developments in the Belgian Congo, 711, 723
Ostrich feather industry, South African, 533
Oversea settlement, 460

P

Paget, Sir Richard A. S., Bt., *paper*, fused silica, 323; silver medal awarded for his *paper*, 564
Papua, the resources of, 550
Parker, Dr. W. Rushton, *disc.*, sun, sea and open-air treatment of disease, 82; *disc.*, death-watch beetle, 269; *disc.*, new uses for rubber, 286; *disc.*, recollections of some notable scientific men, 579; *disc.*, the Amazon Valley, 508

Parnacott, A. E., *letter*, treatment of death-watch beetle, 302
Parry, M. S. *disc.*, new uses for rubber, 285
Parsons, Hon. Sir Charles A., F.R.S., *disc.*, fused silica, 336
Patchouli leaves and oil trade of Singapore, 355
Pearl fishery of Manaar, 784
Pencil cedar from East Africa, 818
Pendulum, the free, *paper* by F. Hope-Jones, 446
Persia, lack of communications and of transport, 131
Peter le Neve Foster prize, *notice*, 849
Photography, aerial, and surveying, 784
——— certain fundamental problems in, *Cobb Lectures*, by Dr. T. Slater price, F.R.S., 725, 739, 753
———in science, industry and medicine, *paper* by T. Thorne Baker, 495
Pick, Frank, *disc.*, London traffic, 438
Pickard, Colonel J. A. A., *disc.*, London traffic, 439
Pig breeding in Scotland in 1923, 303
Pineapple industry in South Africa, 860
Play-bills and theatrical programmes (Enthoven collection) 803
Poland, Ernest, *chair*, furs and the fur trade, 603
Pope, Sir William J., F.R.S., *paper*, the outlook in chemistry (*Trueman Wood Lecture*), 581
Porcelain and pottery industry of Japan, 256
Porritt, B. D., *disc.*, new uses for rubber, 285
Portugal, social conditions in, 568
Powys, A. R., *disc.*, preservation of ancient monuments and historic buildings, 129; *disc.*, death-watch beetle in timber roofs, 268
Price, Dr. T. Slater, F.R.S., *Cobb Lectures*, certain fundamental problems in photography, 725, 739, 753
Prince, Major C. E., *disc.*, the free pendulum, 459
Prune growing in France, 398
Pyrethrum flowers in Japan, 621

R

Rackham, Bernard, *chair*, forgeries of ancient stained glass, 52
Red oxide of iron industry in Malaga, 271
Redmayne, Sir Richard A. S., presentation of medal to, 13; *chair*, mineral wealth of the pre-Cambrian in Canada, 683
Reid, Walter F., *disc.*, furs and the fur trade, 604
Resin, production of by the Harzgesellschaft, 71
Rhubarb in Szechwan, 782
Ribbon industry of St. Etienne, 736
Rice, G., *disc.*, furs and the fur trade, 604
Richardson, E. W., disc, the Amazon Valley, 508
Rideal, Dr. Eric Keightley, *Cantor Lectures*, colloid chemistry, 830, 838, 849
Roberts, Charles H., *disc.*, commercial future of the backward races, 251
Robertson, Sir Robert, F.R.S., *disc.*, chemical research in India, 491
Robinson, Dr. J., *paper*, wireless navigation, 516; beam system of wireless telegraphy, 619
Robinson, R. L., *paper*, forests and timber supply of North America, 360
Rodman, Dr. G. H., *disc.*, photography in science, industry and medicines, 504
Rogers, Lieut.-Col. Sir Leonard, presentation of medal to, 13
Ronaldshay, Earl of, presentation of medal to, 13; *chair*, art of the Pal empire, 697, 703
Rothfeld, Otto, *paper*, co-operative banking in India, 373
Rowland, Father J. P., *disc.*, the free pendulum, 459
Royal Botanic Gardens, Kew, *paper* by Dr. A. W. Hill, F.R.S., 87
Rubber in Sumatra, 305
———, new uses for, *paper* by P. J. Burgess, 276
——— production of in Ecuador, 534
Rumball, H. Medlicott, *disc.*, the West Indies, 69
Rutherford, R., *disc.*, the West Indies, 69; *letter*, 71
Ryan, G. M., *disc.*, the Amazon Valley, 509

S

Saklatvala, S., *disc.*, co-operative banking in India, 383
Salt, manufacture of in India, *paper* by Sir Richard M. Dane, 402
Sandalwood oil production in Mysore, 648
Saunders, A. L., *disc.*, art of the Pal empire, 706
Sawmills in France, 820
Schilowsky, Pierre, *disc.*, wireless navigation, 529
Schoenfeld, Louis N., *disc.*, the geology and mineral resources of Cyprus, 646
Schryver, Prof. S. B., *disc.*, the fishing industry, 396
Scientific men, personal recollections of some notable *paper* by Alan A. Campbell Swinton, F.R.S., 571
Scott, E. Kilburn, *disc.*, commercial future of the backward races, 252
Scott, Miss Mary, wax flower making in Victorian times, 764
Scrutton, J. Herbert, *disc.*, wireless navigation, 529
Sculpture, early Chinese, 494
Sericulture in Algeria, 570
Severn barrage scheme, 784
Seward, Prof. C. A., F.R.S., *chair*, the work of the Royal Botanic Gardens, Kew, 99, 101
Shaughnessy, E. H., *disc.*, the beam system of wireless telegraphy, 618
Shine, E., *disc.*, the work of the Royal Botanic Gardens, Kew, 101
Shipbuilding on the Clyde, 356
Silica, fused, *paper* by Sir Richard A. S. Paget, Bt., 323
Silk, artificial, manufacture of in France, 784
——industry in Hungary, 569
——————— Valencia, 134
——*Journal*, 570
—— production in the Empire, 570
Simpson, Colonel C. N., *disc.*, photography in science, industry and medicine, 504
Sinnatt, F. S., appointment as assistant director of fuel research, 399
Sir George Birdwood Memorial Lecture, archives of the Honourable East India Company, by William Foster, 106
Sisal hemp production in the Empire, 622
Slee, Commander J. A., *disc.*, wireless navigation, 528
Sleeping sickness remedy, "Bayer 205," 253
Slippers, knitted bead, 606
Smith, Sir Cecil Harcourt, retirement from directorship of Victoria and Albert Museum, 570
Smith, G. Albert, *paper*, cinematography in natural colours, 214
Smith, Lieut.-Col. J. Obed, *disc.*, Empire settlement, 147
Smith, Overingenieur Dr. Sigurd, presentation of medal to, 13
Smokeless fuel, 859
Society's house: subscriptions, 119, 209, 387
South African dried fruit and pineapple industries, 357
Stained glass (ancient) forgeries of, *paper* by J. A. Knowles, 38; *letter*, G. Wüthrich, 55
Stebbing, Prof. E. P., presentation of medal to, 13
Stelling, Robert, *disc.*, vocational tests, 300
Stevens, Dr. H. P., *disc.*, new uses for rubber, 284
Stewart-Clark, Sir John, Bt., *obituary*, 288
Sulphur industry of Chile, 33
Sumac, American *versus* European, 154
Sun, sea and open-air treatment of disease, *paper* by Sir Henry Gauvain, 74
Swiney prize, *notice*, 2; awarded to Prof. Sir Paul Vinogradoff, F.B.A., 223; annual report, 565
Swinton, Alan A. Campbell, F.R.S., vote of thanks to chairman, opening meeting, 14; *chair*, Mann Juvenile Lectures, 119, 137; *paper*, personal recollections of some notable scientific men, 571; *disc.*, the outlook in chemistry, 590; *chair*, results from the beam system of wireless telegraphy, 607, 620
Sykes, Brig.-Gen. Sir Percy M., *disc.*, Arabs in art and literature, 662

T

Tar sands, Canadian, 116
Taylor, George William, *obituary*, 206
Teak plantations of Milampur, 190
Thomae, F. A. W., *disc.*, the geology and mineral resources of Cyprus, 646
Thomas, Carmichael, annual meeting, 568
Thornton, J. G., *disc.*, sun, sea and open-air treatment of disease, 83
Thorpe, Prof. Jocelyn, F., F.R.S., *paper*, chemical research in India, 478
Tobacco industry, South African, 551
Torday, E., *disc.*, recent developments in the Belgian Congo. 722

Tower, Walter, *disc.*, forgeries of ancient stained glass, 54
Towler, Lieut.-Colonel H. F., *disc.*, wireless navigation, 530; *letter*, 531
Transport in Persia, 131
Tredwen, E. B., *disc.*, Victoria Dock district and its roads, 474
Tree-planting machine, 421
Trueman Wood Lecture, the outlook in chemistry, by Sir William J. Pope, F.R.S., 581
Tucker, Major W. S., presentation of medal to, 13
Tunny fish industry of Tunisia, 512
Turkey, industry in, 820
Tymms, Captain F., *disc.*, wireless navigation, 530

U

Upjohn, A. A., *disc.*, forgeries of ancient stained glass, 55

V

Veitch, Sir Harry James, *obituary*, 605
Veneer industry of Finland, 103
Vermilion, manufacture of in Hong Kong, 621
Victoria and Albert Museum, 494, 552, 570, 666, 724, 803
Victoria Dock district and its roads, *paper* by Sir Henry Maybury, 464
Vinogradoff, Prof. Sir Paul, awarded Swiney prize, 223
Vocational tests, *paper* by Dr. Charles S. Myers, F.R.S., 291
Voelcker, Dr. J. A., *disc.*, the West Indies, 70; *disc.*, the work of the Royal Botanic Gardens, Kew, 100; *disc.*, Indian ordnance factories, 187; *disc.*, chemical research in India, 490; annual meeting, 567

W

Wade, F. C., *disc.*, Empire settlement, 148
Wales, H.R.H. Prince of, Albert medal awarded to, 463
Walker, F. W., *paper*, commercial future of the backward races, 239
War cemeteries, *paper* by Major-General Sir Fabian Ware, 344
Ware, Major-General Sir Fabian, *paper*, war cemeteries, 344; silver medal awarded for his *paper*, 564
Waring, Francis John, *obituary*, 218
Warren, Edward P., *disc.*, preservation of ancient monuments and historic buildings, 129
Water-power in New Zealand, 134
—— of the St. Lawrence, 372
—— powers of Canada, 783
—— resources of Dutch East Indies, 320
Watkins, C.G., *disc.*, vocational tests, 299
Wax, Madagascar ant, 688
Wax flower making in Victorian times, 764
Webb, Sir Aston, P.R.A., *chair*, preservation of ancient monuments and historic buildings, 131; *chair*, death-watch beetle in timber roofs, 260
Wenger, Albert Francis, *obituary*, 288
West Indian agricultural college, 256
West Indies, *paper* by Viscount Burnham, 60
Whaling in Ross Sea, 256
—— Norwegian, industry 860
Wileman, Miss E. St. John, *disc.*, Empire settlement, 150
Wine glasses, Jacobite, 443
Wireless navigation, *paper* by Dr. J. Robinson, 516
—— telegraphy, results of the beam system of, *paper* by Senatore G. Marconi, 607
Woods, Australian, for pulp and paper manufacture, 419
Woodward, William, *disc.*, death-watch beetle in timber roofs, 266
Wolff, Henry William, *disc.*, co-operative banking in India, 382
Wool fur, 443
—— industries, recent progress in the, *Cantor Lectures*, by Prof. Aldred F. Barker, 861, 873
—— industry of Czechoslovakia, 647
Wuthrich, G., *letter*, forgeries of ancient stained glass, 55

Y

Yarrow, Sir Alfred, Bt., *disc.*, London traffic, 433
Yate, Colonel Sir Charles E., Bt., M.P., *disc.*, Survey of India, 206; *disc.*, commercial future of the backward races, 252
Young, Brig.-Gen. H. A., *paper*, Indian ordnance factories 175; silver medal awarded for his *paper*, 565
Yusuf-Ali, A., *disc.*, art of the Pal empire, 704

Z

Zorn, D. F. L., *disc.*, new uses for rubber, 286
Zuyder Zee, reclamation of, 666
